ON Feb. 29th the driver of a tramcar was summoned before a magistrate's court to answer the following charge. Over a year ago, in January, 1907, the car which he was driving ran into a cab, the driver of which, a man called Chebance, was thrown to the ground. In his fall he sustained severe injuries and he died six months afterwards. His widow claimed 10,000 francs (£400) damages. The court held the car-driver responsible for the accident but it decided that expert evidence was necessary to discover whether the cabman's death was really due to the injuries which he sustained in his fall. The judgment was an interesting pronouncement and I will quote from it, as it affords an excellent comment on the paragraph which I wrote last week about the professional scandal regarding certificates for compensation. The judgment is to the effect that the evidence shows a state of affairs that is all too common in accident claims—that is to say, the intervention of a commission agent, who by the exercise of a vivid imagination, backed by medical certificates, has tried to make the defendant pay compensation money, the ultimate destination of which is only too evident. This is clear from a study of the letter of claim written on April 3rd by the agent and signed by Chebance, to which a medical certificate is appended, with a letter in the same hand and signed by the widow, and with a third letter, dated Feb. 4th, 1908, also written by the same person, who this time, instead of getting the woman's signature, signed it outright "Widow Chebance" in his own hand, since it is obvious that the woman in question could not have written such a good signature. It is also suspicious that a cab-driver with hardly enough means to get properly looked after outside hospital could have afforded a consultation of two medical men, and in this connexion it must be remembered that the commission agent had intervened on the very first day. Taking these facts into consideration, the court has commissioned a medico-legal expert to take the evidence of the two practitioners who had medical charge of Chebance and to report whether his death on June 25th, 1907, was really the result of the accident in the preceding January.

Military Hygiene and Epidemiology.

The decree instituting a Supreme Commission of military hygiene and epidemiology, which is to last until 1914, has recently been slightly modified, as follows. The commission is to be composed of 20 members, one *ex-officio*, the Director-General of the Army Medical Service, and 19 to be nominated by the Minister of War. Among these 19 are to be the following: one senator, one deputy, two civil medical men chosen from the members of the Academy of Medicine, seven army surgeons, either surgeon-inspector-generals or surgeon-inspectors of the active or reserve forces, and a general officer of engineers.

The Adulteration of Drugs.

The Parliamentary Commission on Public Health has approved a Bill to repress fraudulent dealing in drugs. It provides for the regular inspection, not less often than once a year, of druggists' shops, surgeries of medical men and veterinary practitioners, pharmaceutical laboratories, herbalist and grocery shops, hairdressers' and perfumers' establishments, factories and stores of natural and artificial mineral waters, and in general all places where pharmaceutical or hygienic commodities are made, stored, or exposed for sale. Pharmacists, druggists, and all purveyors of pharmaceutical products will be liable to produce any of these which they may have on their premises for inspection by officers whose powers will be exactly laid down and who will be appointed by an order of the Public Administration.

The Roland Bonaparte Benefactions for Scientific Research.

At a meeting of the Academy of Science on March 2nd Prince Roland Bonaparte offered to put at its disposal the sum of 100,000 francs not to be invested as capital but in a series of annual grants to be awarded quickly. He wishes these grants to stimulate progress by helping the researches of workers who have already shown some promise by their original investigations but who, not being members of the Academy, are hampered by lack of funds in pursuing them. The Academy has decided that applicants must ask for the grants before Jan. 1st in each year, except in the present year, when May 1st will be the day. The successful applicants must during the ensuing year submit to the Academy a summary of the use that they have made of their subsidies and the results which they have obtained. If anyone who has received a grant fails to send in his report in the specified time he will be disqualified from any further aid from the fund. The Academy will have the sole right of publishing the discoveries that are made with the help of these grants, whatever form they may take. If this condition is transgressed the offender will forfeit any claim to a further subsidy.

Congress of Climatotherapy and Urban Hygiene.

This congress will be held at Biarritz from April 20th to 26th. The mornings of each day will be devoted to the reading of papers and the afternoons to excursions. On April 25th the congress will be held in Spain at San Sebastian, and on the following day it will meet at Arcachon. The meetings are open not only to medical men but also to anyone who is interested in the two subjects under discussion.

March 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Serum Diagnosis of Syphilis.

THE serum diagnosis of syphilis according to the methods devised by Dr. Bordet and Dr. Gengou of Paris and by Dr. Wassermann of Berlin was the subject of several papers read and discussed at meetings of the Berlin Medical Society on Feb. 19th and 26th and March 4th. Dr. Fleischmann said that the Bordet-Gengou reaction was of great value, as in 89 cases of syphilis with manifest symptoms a positive result was obtained; in 64 patients known to be syphilitic but not showing manifest symptoms the reaction was positive in 52 per cent. and in 38 cases of non-syphilitic persons it was negative. He considered that the reaction was of special importance when in certain cases symptoms have developed which were suspected to be of syphilitic origin, although there was no antecedent history of the primary stage of that disease. A positive reaction might be regarded as a certain proof that the patient was syphilitic. The result of the reaction might, moreover, be of value in deciding whether anti-syphilitic treatment was indicated or not. Dr. Blaschko gave a summary of 400 cases examined by himself and Dr. Julius Citron. In no instance did non-syphilitic patients suffering from eczema, psoriasis, balanitis, herpes, and cancer give a positive reaction. In some doubtful instances the result of the reaction, whether positive or negative, was always verified by the further development of the case. Observations made on 300 syphilitic patients gave the following results. During the primary stage the reaction was positive in 90 per cent.; during the secondary stage attended with obvious symptoms it was positive in 98 per cent.; during the secondary stage without characteristic symptoms it was positive in 80 per cent.; during the tertiary stage with obvious symptoms it was positive in 91 per cent.; and during the tertiary stage without characteristic symptoms it was positive in 57 per cent. Under anti-syphilitic treatment the positive reaction might sometimes become negative but in some cases it remained unaltered. Dr. Blaschko, however, stated that a positive reaction was not to be regarded as indicating an unfavourable prognosis. Many persons who had given such a reaction had nevertheless been to all appearance in good health for years, were married, and had healthy children. Obviously the positive reaction must spontaneously become negative after the lapse of some years. A positive reaction in patients who did not show characteristic symptoms was not an indication for a continuation or repetition of antisyphilitic treatment, because it often happened that even after prolonged treatment by Fournier's intermittent method the reaction remained positive. Dr. Citron read a paper on Modern Researches in Syphilis and their Value in Connexion with Treatment. He said that in recent times our knowledge of syphilis had been

Williams and Isaac Davies do attend the said committee to-morrow, at half-past eleven of the clock." The House thereupon made an order requiring the attendance of the two gentlemen.

The Funds of the General Medical Council.

The return of the receipts and expenditure of the General Medical Council and of the branch councils, and also of the receipts and expenditure of the Dental Registration Fund, for the year 1907 has just been presented to Parliament.

Tropical Diseases Research.

The report of the Advisory Committee for the Tropical Diseases Research Fund for the year 1907 has been presented to Parliament.

A Public Health Bill.

Mr. COOPER has presented a Bill in the House of Commons "to amend the Public Health Act, 1875, and the Local Government (England and Wales) Act, 1888." It has been read a first time.

HOUSE OF LORDS.

WEDNESDAY, MARCH 18TH.

Malta Fever.

Earl CAWDOR in his speech on naval matters incidentally asked the First Lord of the Admiralty what had happened to the goats in Malta through the agency of which Malta fever had been spread amongst the sailors of the fleet.

Lord TWEEDMOUTH, in reply, said that the goats in Malta still lived. It was their milk that spread the microbes. The way in which the naval authorities had got rid of Malta fever was by preventing the sailors and marines of the fleet from using any of the goats' milk. As a matter of fact the Malta goat lived in a very dirty manner. It fed on filthy garbage and consequently it was liable to get its milk contaminated.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 18TH.

Trained Nurses in Ireland.

Mr. CULLINAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he would state what proofs of efficient teaching, of efficient examining, and of the possession of adequate *matériel* and of a capable and industrious staff the Local Government Board required before sanctioning any hospital for the training of nurses, whether trained or merely qualified; and whether they would take the medical profession generally into their confidence on those points.—Mr. BIRRELL replied (by written answer): Under the Local Government Board's Nursing Order, 1901, a trained nurse means any person who has resided for not less than two years in a general clinical or other hospital recognised by the Board and who, after examination, has obtained from such hospital a certificate of proficiency in nursing; and the term qualified nurse means any person who, after examination, has obtained a certificate of proficiency in nursing from any (1) public general hospital, or (2) workhouse infirmary and fever hospital, or (3) nursing institution, that may be recognised by the Board as an efficient school for medical and surgical nurses. The Board require, as evidence of the due training or qualification of a nurse, the production of the original certificate of proficiency from a recognised hospital. Before recognising for the purpose in question any hospital other than a general clinical hospital the Board make careful inquiries respecting such hospital. The Board have always received and welcomed assistance from the medical profession, both as regards the general question of recognition of the training of nurses and as regards the capacity for teaching of any particular hospital. It may be added that a general clinical hospital is one recognised by examining bodies for the instruction of medical students.

Proof Spirit in Temperance Drinks.

Mr. STAVELEY-HILL asked the Chancellor of the Exchequer whether he would state the number of samples of herb beer and other beverages sold as temperance drinks analysed at the Government laboratory during the past three years; the number found to contain more than 2 per cent. of proof spirit; and the percentage of proof spirit there disclosed.—Mr. ASQUITH, in reply, furnished the following tabular statement:—

Herb and Botanic Beer and similar Beverages examined in the Government Laboratory.

Year to March 31st.	Number of samples containing proof spirit in excess of legal limit of 2 per cent.	Containing proof spirit of—			Highest percentage of proof spirit contained in one sample.
		3 per cent., but less than 4 per cent.	4 per cent., but less than 6 per cent.	6 per cent. or more.	
1905	361	78	42	8	8·3 ginger beer.
1906	349	58	35	8	9·5 ginger beer.
1907	422	71	37	8	10·5 herb beer. 12·3 dandelion stout.
April 1st, 1907, to March 10th, 1908	417	81	32	6	8·5 herb beer.
Total	1549	288	146	30	—

The total number of samples examined in the year to March 31st, 1905, was 1011; in 1906, 924; in 1907, 1133; and from April 1st, 1907, to March 10th, 1908, 1079—a grand total of 4147.

THURSDAY, MARCH 19TH.

Medical Referees and the Workmen's Compensation Act.

Mr. ARTHUR HENDERSON asked the Secretary of State for the Home Department whether any case had been considered by the medical referees appointed under the Workmen's Compensation Act; and, if so, in what trade and with what result.—Mr. GLADSTONE replied: The total number of cases considered by medical referees in the six months from July 1st, 1907, the date on which the Workmen's Compensation Act, 1906, came into force, up to Dec. 31st, 1907, after which date figures are not yet available, is 117. The numbers in the respective branches of employment were as follows: Railways, 4; factories, 27; mines, 64; engineering, 2; building, 9; agriculture 3; not stated, 8. I cannot give the results, as the reports of the referees are not made to the Home Office but to the county court and other persons. Such information as is furnished to the Home Office is principally required for the proper payment of the fees. I should like to add that I do not think any trustworthy inference as to the working of the provisions of the new Act can be drawn from the results of the first six months of its operation.

Mr. WEDGWOOD: May I ask whether any steps are being taken to see that the medical referees have not previously been interested in the cases as certifying surgeons or otherwise?

Mr. GLADSTONE: Yes, steps have been taken.

Meat Inspection in Scotland.

Answering Mr. CATHCART WASON, Mr. SINCLAIR, the Secretary for Scotland, said: I am informed that there are six qualified veterinary surgeons in Glasgow who act as inspectors for inspecting cattle in public sale yards. Three act under the Diseases of Animals Act and three under the Public Health Acts. None of these inspectors have any official information from Dublin that cattle unfit for human food are sent to Glasgow to be consumed there. In all such cases, however, the carcasses of the animals are seized and destroyed.

In reply to a question put by Mr. MORTON, Mr. SINCLAIR said: There is no provision requiring local authorities in Scotland to see that animals exposed for sale in any market, whether provided with weighing machines or not, are inspected by a veterinary surgeon and certified as to their fitness for human food. There is no power to fix a standard of inspection, but on Oct. 19th, 1899, the Local Government Board for Scotland issued a circular suggesting that in the inspection of tuberculous carcasses of cattle the principle laid down in the report of the Royal Commission on Tuberculosis of 1898 should be followed. There is no intention to recommend any standard for the inspection of living animals.

Insane Persons and Marriage.

Mr. EDWARD DUNN asked the Prime Minister whether he was aware that, according to a recently published report of the Commissioners in Lunacy, of 123,938 persons certified as incurably insane in England and Wales over 40 per cent. were married, and that consequently upwards of 57,000 persons were thus condemned by law to enforced celibacy; and whether, having regard to the fact that the greater number of such persons were in poor circumstances and to the evils arising from the existing state of the law he would afford facilities for the consideration of the Bill for the amendment of the present law of divorce.—Mr. ASQUITH (in the absence of Sir HENRY CAMPBELL-BANNERMAN) replied by written answer: My right honourable friend has asked me to answer this question for him. The number of persons certified to be insane and known to be under care is, I understand, as stated. Of the males so certified the official statistics show that 47·6 were married and of the females 45 per cent. These persons, however, are not certified as incurably insane and a proportion of them recover. The Government cannot undertake to afford facilities for the consideration of the Bill for the amendment of the present law of divorce.

FRIDAY, MARCH 20TH.

Housing of the Working Classes in Ireland.

Mr. HOGAN, in moving the second reading of the Housing of the Working Classes (Ireland) Bill, explained that the measure was designed to facilitate the granting of loans for the erection of houses for the working classes in the cities and towns of Ireland and also for improving the administrative machinery in connexion with this question.

Mr. CLANCY, in supporting the motion, said that one was appalled by the state of the housing of the working classes in all the cities and towns in Ireland. In Dublin the state of things amounted to a national scandal. There, in 1903, out of 70,000 families there were no fewer than 21,747 families living in one-room tenements. Comparing the condition of affairs in Ireland with that in England and Scotland he said that in Manchester there were 0·04 per cent. of one-room tenements having five or more occupants, in Liverpool 0·22 per cent., in London 0·57 per cent., in Edinburgh 1·80 per cent., in Glasgow 3·28 per cent., while in Dublin there were 8·69 per cent. Overcrowded as Glasgow was it was still not so bad as Dublin. Local authorities were being urged to build sanatoriums all over the country, but what earthly use was it to erect sanatoriums if they allowed these breeding haunts of consumption to exist by the thousand in Dublin and by the hundred in small centres of Ireland? If the satisfactory housing of the people was not carried out more rapidly in the future than it had been during the last 30 years then the prospect was one to make his heart sink within him. He did not suppose that any objection to the provisions of the Bill would be taken except with respect to the money clauses.

Mr. LONSDALE, in the course of the debate, said that the Ulster Members were in favour of improving housing for the working classes in Ireland which would promote the welfare of the whole people. There had been great improvement but further financial aid from the State as proposed by the Bill was required. The census figures showed that there was still much overcrowding, especially in Dublin, where in 1901 40·6 per cent. of the population occupied overcrowded dwellings. Belfast, on the other hand, had only 8·28 per cent. of its population in overcrowded conditions. Correspondingly the death-rate was lower in Belfast than in Dublin. While he cordially supported the principle of the Bill he thought that some of the novel provisions required such careful consideration that he suggested the measure should be referred to a Select Committee.

Mr. BIRRELL (Chief Secretary to the Lord Lieutenant of Ireland), replying to the debate, said that it would be impossible for the House to refuse a second reading to a measure which had received such happy and unusual support from all quarters of the House. The city of had been a decrease in the death-rate of 15 per cent. In the opinion of Mr. Gage the National Sanitarium Association had materially helped in this decrease. During the course of its deliberations the conference appointed a deputation to approach the Government and to solicit an increase from $1.50 a week for the patients to $5 per week. The Premier (Hon. Mr. Whitney) stated for his government that the proposition would receive at their hands more than ordinary consideration.

Hospitals and Charities in Ontario.

The report of the Inspector of Hospitals and Public Charities in Ontario for the year ending Sept. 30th, 1907, has been laid before the Ontario legislature now in session. There are now 65 hospitals in Ontario, four new ones having been established in the year—35 refuges, 31 orphanages, three homes for incurables, two convalescent homes, two Magdalen asylums, and 28 county houses of refuge, each of which shared in the Government grants. The hospitals have enjoyed a most successful and prosperous year and the total number under treatment during the year was 45,551, not including those who received medicine and treatment as outside patients. The expenditure of $1,415,140 for the support and maintenance of the hospitals of Ontario indicates a spirit of liberality that has never been equalled in any past year in the province. Referring to hospitals for consumptives the inspector in his report says that there is a necessity for some action being taken by the Government which will result in the establishment of sanatoriums in accordance with the Act relating thereto. In Ontario during the past year 2667 persons died from tuberculosis. The Government grant to every municipality establishing a sanatorium for the treatment of consumptives is $4000 and afterwards $1.50 a week is paid by the Government for each patient's maintenance while in residence. The municipalities in Ontario, however, have been slow to take advantage of the provisions of this Act, even though the many instances of consumption being cured in Ontario afford sufficient evidence to justify the establishment of these sanatoriums. The inspector found during the course of his visits of inspection to the various hospitals that want and suffering were particularly evident in immigrants newly arrived from the old lands and rather severely criticises the Federal Government with regard to its immigration inspection laws.

Annual Report of Montreal General Hospital.

At the annual meeting of the supporters of the Montreal General Hospital held on Feb. 18th there was announced a deficit of $20,000 for the year 1907. In referring to the work that this hospital has done in the last half-century the chairman of the board of governors said that in 1857 the number of indoor patients who received attendance in the wards of the hospital was 966, and in the outdoor departments, 4953, or a total of 5919, as against 54,187 for 1907. The number of patients who passed through the wards of the hospital in 1907 was 3347; out-patients numbered 50,840, being 3858 in excess of 1906. During the year an addition to the nurses' home had been completed at a cost of $16,623 and fire-proof galleries between the two surgical wards at a cost of $11,626. The income from all sources for the past year amounted to $105,907 and the expenditure to $124,738. To the endowment fund a total of $39,182 was added during the year, which brings that fund up to $137,182.

March 14th.

Obituary.

WILLIAM CLARKSON, L.F.P.S. GLASG., L.R.C.P. EDIN.

IN the death of Mr. William Clarkson of West View, Morpeth, a striking personality has disappeared from the medical practitioners of Mid-Northumberland. A native of Wiston, in the upper ward of Lanarkshire, from its parish school he entered the University of Glasgow at an early age. He studied first in the arts classes and then entered on the study of medicine, obtaining several distinctions. Having taken the Licence of the Faculty of Physicians and Surgeons, Glasgow, in 1856, he held appointments and assistantships in several places both in Scotland and England. In 1865 he was elected surgeon to the dispensary at Morpeth. The success which attended his treatment of his cases during a simultaneous outbreak of small-pox and scarlet fever led to his obtaining several public appointments. He took the Licence of the Royal College of Physicians, Edinburgh, in 1874. Among the appointments which he held were medical officer of health of the borough of Morpeth, surgeon to the workhouse of Morpeth Union, Poor-law medical officer and vaccination officer to several large parishes in Morpeth Union, and medical officer of health to Morpeth rural district council, the area of which is one of the largest and most populous in the country, including then what is now said to be the largest colliery in the world, raised some years ago to the independent position of Ashington urban district with a vigorous council of its own managing the health affairs of a population of 20,000. He was also medical officer to Pegswood colliery. His reports as a medical officer of health were recognised by the profession and by the public as models of what such reports should be as to the use of admirable English, the precision of acute inference, and valuable suggestions. The reputation gained at the dispensary secured him an extensive private practice. Having retired from the position of medical officer of health of the borough he was elected to the town council and in 1868 was chosen as mayor. From all the other appointments he retired some years ago except those of Poor-law and vaccination officer for the parishes alluded to. These he retained until his death which occurred on March 6th in the seventy-ninth year of his age. In his latter less arduous years he frequently lectured on Scottish songs, especially on those of Burns and of the Jacobite era, illustrating his subject matter by singing appropriate songs in his own inimitable style. These lectures were always freely given on behalf of literary, charitable, or religious institutions.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Isaac R. Trimble, professor of anatomy and surgery in the College of Physicians and Surgeons, Baltimore.—Dr. Richard Douglas, formerly professor of gynæcology in the Vanderbilt University, Nashville.—Dr. Robert Luedeking, professor of children's diseases in the Washington University, St. Louis.

Medical News.

UNIVERSITY OF OXFORD.—Mr. H. R. Dean, B.M., B.Ch., New College, M.R.C.P. Lond., formerly Senior Demy of Magdalen College, has been elected to a Radcliffe Travelling Fellowship for three years.—The following degrees have been conferred:—

B.M., B.Ch.—Samuel Ernest Whitnall, Magdalen College.
B.Sc.—Harvey Sutton (M.B. Melb.), New College.

—The degree days for next term are as follows: Thursday, April 30th, at 10 A.M.; Saturday, May 23rd, at 2.30 P.M.; Thursday, June 18th, at 10 A.M.; Thursday, June 25th, at 10 A.M.; and Saturday, July 11th, at 10 A.M.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful in the subjects indicated:—

DEGREES OF M.B. AND CH.B.

Second Examination, Part A., Anatomy and Physiology.—A. Adams, A. Bamforth, J. E. Barnes, J. Campbell, A. A. Dear, E. S. Miller, Phœbe M. Powell, W. R. Wade, and T. W. Wadsworth.
Part B., Materia Medica.—H. el Arculli, T. C. Clarke, and W. F. Young.
Final Examination, Part I.—J. A. Parkes and A. A. Rees.
Part II.—A. C. Edwards, J. F. L. McCann, and A. M. M. Roberts.

DIPLOMA IN DENTAL SURGERY.

Second Examination.—G. P. P. Clapham.
Third Examination.—R. P. Allenby.

DIPLOMA IN TROPICAL MEDICINE.

A. M. Caverhill, M.B., Ch.B. Edin.; Major G. Dansey-Browning, R.A.M.C., M.R.C.S. Eng., L.R.C.P. Lond.; Major J. Davidson, I.M.S., M.D. Edin.; A. M. Dowdall, M.R.C.S. Eng., L.R.C.P. Lond. L. L. Joshi, M.D. Cornell Univ.; C. V. M. E. Le Fanu, M.B., Ch.B. Aberd.; C. W. L. Luethgen, M.B., Ch.B. Edin.; F. W. McCay, L.R.C.P. & S. Edin., L.F.P. & S. Glasg; Major G. W. Tate, R.A.M.C., M.B., B.Ch. Irel.; and R. Whyte, M.B., B.Ch. Irel.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—S. Speelman (Section II.), Amsterdam; and A. H. Turner (Sections I. and II.), Leeds.
Medicine.—E. J. Crew (Section II.), Guy's Hospital; H. E. Middlebrooke (Section II.), London Hospital; and A. H. Turner (Sections I. and II.), Leeds.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Aberdare, Urban District Council Education Committee.—School Medical Officer. Salary £220, rising to £250.

Ayr District Asylum.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

Bedford County Hospital.—House Physician. Salary £60 per annum, with apartments, board, and laundry.

Birmingham and Midland Free Hospital for Sick Children.—Resident Medical Officer, also Resident Surgical Officer. Salary in each case £80 per annum, with board, washing, and attendance.

Bristol Royal Infirmary.—House Physician. Salary £100 per annum, with apartments, board, and laundry.

Cambridge, Borough of.—Medical Officer of Health. Salary £500 per annum.

Cambridgeshire, &c., Asylum, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.

Canterbury Borough Asylum.—Assistant Medical Officer, unmarried. Salary £140 per annum, with board, lodging, washing, and attendance.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence. (Incorrectly given last week as £70 per annum.)

Chelsea Guardians.—Medical Officer for No 3 Relief District. Salary £100 per annum and fees.

Cheltenham General Hospital.—House Physician, unmarried. Salary £70 per annum, with board and lodging.

Cheshire County Council Education Committee.—Two Assistants to the Medical Officer of Health. Salary in each case £350 per annum and travelling expenses.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, washing, and residence. Also Clinical Assistant.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Physician to Out-patients.

Derbyshire, Devonshire Hospital, Buxton.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

Dublin, Royal Victoria Eye and Ear Hospital, Adelaide-road.—House Surgeon. Salary £40 per annum, with board and residence.

Dumfries and Galloway Royal Infirmary.—House Surgeon, also Assistant House Surgeon. Salaries £80 and £40 respectively, with board and lodging.

East Suffolk County Education Committee.—School Doctor. Salary £350 per annum, with out-of-pocket expenses.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £70 per annum, with board and washing.

Edinburgh District Asylum, Bangour Village.—Second Assistant Physician, unmarried. Salary £120, with board, apartments, and laundry.

Egyptian Government, Kasr El Ainy Hospital.—Resident Surgical Officer. Salary £250 per annum, with quarters, servants, washing, coal, and light.

Grocers' Company.—Two Scholarships for Research in Sanitary Science value £300 a year each, with allowance to meet the cost of apparatus and other expenses.

Hastings, St. Leonards, and East Sussex Hospital.—Assistant House Surgeon for six months. Salary £20, with residence, board, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Salary £25.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon for six months. Salary £20. Also House Physician for six months. Salary £20. Also Assistant Casualty Medical Officer for six months. Salary £20. All with board and residence.

Hospital for Women, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £60 per annum.

Ipswich, East Suffolk and Ipswich Hospital.—Senior House Surgeon. Salary £80 per annum.

King's College Hospital.—Senior Medical Registrar and Tutor.

Leyton Urban District Council.—Assistant Medical Officer of Health. Salary £250 per annum, rising to £300.

Liverpool Dispensaries.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

London Fever Hospital, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with residence and board.

London School of Tropical Medicine, Royal Albert Dock, E.—Cragg's Research Prize. Value £50.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

Maidstone, West Kent General Hospital.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

Middlesex County Asylum, Upper Tooting, S.W.—Fourth Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

Middlesex Hospital, W.—Assistant Obstetric Physician. Also Second and Third Assistants to the Director of the Cancer Research Laboratories. Salary of Second Assistant £150 and Third Assistant £100 per annum.

National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, W.C.—Registrar. Salary £150 per annum.

Northamptonshire County Council Education Committee.—School Medical Officer. Salary £400 per annum and travelling expenses.

Nottingham General Hospital.—Assistant House Surgeon, also Assistant House Physician. Salary in each case £60 per annum, with board, lodging, and washing.

Rotherham Hospital and Dispensary.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

Royal Navy, Medical Department.—Examination for not less than 15 Commissions.

St. George's Union, London.—Medical Officer. Salary £100 per annum, with fees.

Seamen's Hospital Society, Greenwich, S.E.—Two House Physicians and Two House Surgeons. Salary in each case £50 per annum, with board, residence, and washing.

Sheffield Education Committee.—Assistant Medical Officer. Salary £250 per annum, rising to £300.

Shrewsbury, Salop Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Also House Physician for six months. Salary at rate of £50 per annum, with board and apartments.

South Uist (Southern Division).—Medical Officer. Salary £77 10s.

Southwark Union Infirmary, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

Southport Infirmary.—Resident Junior House and Visiting Surgeon, unmarried, for six months, renewable. Salary at rate of £70 per annum, with residence, board, and washing.

Stafford, Staffordshire General Infirmary.—Assistant House Surgeon. Salary £82 per annum, with board, residence and laundry.

Stoke-on-Trent, North Staffordshire Infirmary and Eye Hospital, Hartshill.—House Physician. Salary £100 per annum, with apartments, board, and washing.

Surrey County Council Education Committee.—Four Assistant Medical Officers. Salary of each £250 per annum, with expenses.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Walsall, Education Committee for the County Borough.—School Medical Officer. Salary £200 per annum.

Warrington, County Borough of.—Assistant Medical Officer of Health. Salary £125 per annum, with board and residence.

West Ham County Borough Education Committee.—Two Medical Inspectors of School Children. Salary £250 per annum, rising to £300 in each case.

Wolverhampton and Staffordshire General Hospital.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

Worcester General Infirmary.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

Worcestershire, Barnsley Hall Asylum, Bromsgrove.—Second Assistant Medical Officer. Salary £150 per annum, with quarters, board, washing, and attendance.

Worcestershire Education Committee.—Inspector of School Children and Midwives. Salary £400 per annum, with travelling expenses. Also Two Assistant Inspectors. Salary £175 per annum, with travelling expenses.

York Dispensary.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Doneraile, in the county of Cork; at Turriff, in the county of Aberdeen; at Erith, in the county of Kent; at Lynton, in the county of Devon; at Worthen, in the county of Salop; and at Loftus, in the county of York.

Births, Marriages, and Deaths.

BIRTHS.

Bennett.—On March 21st, at Hillcrest, Northwood, the wife of Norman G. Bennett, M.A., M.B., B.C., L.D.S., of Brook-street, Grosvenor-square, W., of a daughter.

Lee.—On March 21st, the wife of Fredk. W. Lee, M.R.C.S., L.R.C.P., of Southdown House, Storrington, Sussex, of a son.

Lee.—On March 19th, at 45, Muswell-rise, the wife of William Edward Lee, M.D., F.R.C.S., of 45, Muswell-rise, N., and 36, Finsbury-pavement, E.C., of a son.

MARRIAGE.

Dickson—McLaggan.—On March 25th, at St. John's Church, Buxton, by the Rev. C. C. Nation, M.A., R.D., Vicar, Francis Henry Dickson, M.B., Ch.B. Edin., of 37, Holywell-street, Oxford, youngest son of the late Francis Kennedy Dickson, F.R.C.P. and F.R.C.S., J.P., to Margaret Sophia McLaggan, eldest daughter of the late Alexander McLaggan, of Bombay, and of Mrs. McLaggan, of Lake Chrissie, Transvaal.

DEATHS.

Abud.—On March 23rd, at Mount Park-road, Ealing, Richard Abud, M.R.C.S. Eng.

Attfield.—On the 23rd March, at San Remo, Italy, in his forty-second year, after suffering for five years from consumption and recently influenza, Donald Harvey Attfield, M.A., M.B., formerly Medical Officer of Health at Watford, and afterwards for several years Chief Maritime Medical Officer of Health for the Egyptian Government at Suez; son of Professor Attfield, F.R.S., of Watford. Friends please accept this, the only, intimation.

Lorimer.—On March 25th, at Nelson House, Nelson-street, Oxford-road, Manchester, George Lorimer, M.A., M.D. Edin., of Buxton, son of the late Rev. Archibald Lorimer of Cockenzie, N.B. Deeply regretted. Friends please accept this, the only, intimation.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

committee has issued a circular to all the correspondents of the council schools on the subject in the hope that some lady or gentleman in each parish will volunteer for the work outlined. The education committee may consider the desirability of having hospital collecting boxes permanently established in the schools and a periodical call made from the parents, through the children, in a similar manner as is being done now in very many business houses. Here would be the nucleus of a fund to assist in responding to the calls of the needy cases.

Cardiff Infirmary.—At the meeting of the board of management of the Cardiff infirmary held on March 11th it was stated that there had only been one applicant for the post of house physician to the institution, and he had afterwards withdrawn his candidature. It was decided to advertise the appointment again.

The annual general meeting of the governors and supporters of the Hospital for Women, Soho-square, London, W., will be held at the hospital on Thursday next, April 2nd, at 3 P.M., to receive the annual report of the committee of management and the audited accounts for the year 1907, and to elect governors and members of the committee of management and auditors for the ensuing year.

Donations and Bequests.—The late Mr. George Harrison, of Manchester, bequeathed £10,000 to the Owens College for scholarships or fellowships, or such like purposes as the council of the college may direct, subject to the words "George Harrison" being always associated with the objects provided for by the bequest.—The following bequests have been made under the will of Mrs. Margaret Stern of East Barnet, Herts:—£1000 to the Manchester Royal Infirmary; £500 to the Owens College, Manchester; £250 to the Children's Hospital, Manchester; £500 to the German Hospital, London; and £250 to the Earlswood Asylum for Idiots.

The London Biblewomen and Nurses Mission.—The report for the year 1907 of the nursing branch of the London Biblewomen and Nurses Mission gives some interesting particulars of the useful work which this institution is carrying out by means of a body of trained hospital nurses who nurse the sick poor in their own homes in various parts of London under the name of the "Ranyard Nurses." During the year under notice the number of cases nursed was as follows: maternity, 1164; medical, 3951; surgical, 2784; cases not requiring daily visits, 623; total, 8522. Subscriptions and donations should be sent to the honorary secretary, Miss Andrews, at Ranyard House, 25, Russell-square, W.C., or to Lord Kinnaird, addressed to the Bank of Messrs. Barclay and Co., 1, Pall Mall East, London, S.W.

Complimentary Dinner to Dr. A. Newsholme.—On March 21st a thoroughly representative gathering of all sections of the townspeople of Brighton, as well as of the adjoining town of Hove, attended at the Royal Pavilion, Brighton, on the occasion of a banquet to Dr. Arthur Newsholme as a mark of appreciation of his work for Brighton during the 20 years that he was medical officer of health. When Dr. Newsholme's appointment as principal medical officer of the Local Government Board became known the medical profession in Brighton and Hove contemplated entertaining him at a banquet but it was soon found that it was the desire of even a wider circle than the medical profession that some such gathering should take place; hence the coöperation of the civic authorities and the medical profession. Following loyal toasts and the toast of "The Medical Profession," proposed by the junior Member of Parliament for the borough (Mr. E. A. Ridsdale) and responded to by Mr. H. H. Taylor and Mr. T. Jenner Verrall, the Mayor (Councillor J. P. Slingsby Roberts) submitted the toast of "Our Guest," recalling Dr. Newsholme's great work in Brighton from the year of his appointment as medical officer of health. Dr. Newsholme was given a hearty reception on rising to reply. He spoke of his work in different directions and the gratification it was to him to see the death-rate of the town fall from 18·7 to 14·7 per 1000. Apart from the occasional invasions of that deadly foe, influenza, he saw no reason why it should ever go higher. Referring to the ravages made by tuberculosis and the successful results attained from the system of curative treatment at the Brighton Sanatorium, Dr. Newsholme expressed the hope that the vigorous prosecution of the fight against consumpton would be continued. He believed that, if they did all that was possible, in 20 years consumption would occupy as small a place in the list of deaths in Brighton as enteric fever did at the present time. Dr. Newsholme paid a warm tribute to the work of those under him and expressed a hope that Dr. Duncan Forbes, his successor, would receive the same assistance as he had done.

West Wales Sanatorium.—It is announced that Princess Christian will formally open the West Wales Sanatorium for Consumption at Alltymynydd on July 20th.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Royal Commission on Sewage Disposal.

A sum of £4537 is provided in the Estimates for the expenses of the Royal Commission on Sewage Disposal during the year 1903-09. This Commission, it is stated in a footnote to the Estimates, was appointed in May, 1898, and has issued several interim reports. The Commissioners hope to present a report early in 1908 dealing with the relative merits of different systems of sewage disposal. The work which the Commission has already done on the purification of distillery refuse will probably also be dealt with in this report. An experimental investigation of the effect on streams of sewage effluents of varying degrees of purity has already been commenced for the purpose of enabling the Commission to formulate a series of standards and in its final report the Commission proposes to deal with this matter and also with the means available for purifying various kinds of trade effluents when not mixed with sewage.

The Royal Commission on Tuberculosis.

For the expenses of the Royal Commission on Tuberculosis a sum of £5491 is earmarked in the Estimates for the year 1908-09. This sum compares with £8554 during the last financial year. This Commission was appointed in 1901 to inquire with respect to tuberculosis whether the disease in animals and man is the same; whether animals and man can be reciprocally infected with it; and under what conditions, if at all, the transmission of the disease from animals to man takes place. The Commission was not appointed for any fixed period and the Commissioners state that it is impossible to say definitely when they will be in a position to give a final answer to all the terms of the reference, but every endeavour will be made to terminate the work in the course of the year 1908-09.

The Royal Commission on Vivisection.

In the Estimates of 1903-09 a sum of £550 is set apart for the expenses of the Royal Commission on Vivisection, as against £1058 in the financial year 1907-08. This Royal Commission was appointed in 1906, and according to the footnote to the Estimate it may be expected to last for the greater part of the financial year 1908-09.

Hospitals and Charities in Ireland.

A sum of £17,110 has been placed on the Estimates to pay charges connected with hospitals and infirmaries and certain miscellaneous charitable and other allowances in Ireland. Last year the estimate was £17,139.

The Poisons and Pharmacy Bill.

Five peers and five commoners are to sit on the Joint Committee of both Houses of Parliament which will consider the Poisons and Pharmacy Bill. The names of the peers are Lord Saltoun, Lord Stanley of Alderley, Lord Lawrence, Lord Monk Bretton, and Lord Haversham, and of the members of the House of Commons Mr. Atherley-Jones, Mr. Godfrey Baring, Mr. Idris, Mr. Vincent Kennedy, and Sir John Batty Tuke.

Official Directory of Nurses Bill.

Lord Balfour of Burleigh has presented a Bill in the House of Lords to provide for the establishment of an official directory of nurses. It has been read a first time.

Another Pharmacy Bill.

Mr. Winfrey has introduced into the House of Commons a Bill to amend the Pharmacy Acts. The Bill has the support of Mr. Idris, Mr. Henniker Heaton, Mr. Gulland, Mr. Remnant, Mr. Dobson, Mr. Cowan, Mr. Crooks, Dr. Vickerman Rutherford, and Mr. Ellis Griffith.

The Evidence of a Medical Officer of Health.

An unusual procedure had to be followed last week to procure the attendance of Dr. William Williams, the medical officer of health of Cardiff, at a sitting of a Select Committee of the House of Commons on a private Bill. The chairman of the committee, Mr. Mooney, on March 18th made the following report to the House: "That the parties promoting the Glyncorrwg Urban District Council Bill had stated that the evidence of Dr. William Williams, medical officer of health, Cardiff, and Isaac Davies, of Abergwynfi, schoolmaster, was essential to their case; and, it having been proved that their attendance could not be procured without the intervention of the House, he had been instructed to move that the said Dr. William practitioners who are interested in the welfare of our children will report cases of illness of all kinds which result from the conditions of school life. The amount of illness, hysteria, insanity, and crime which result from our present educational system is beyond calculation.

I am, Sir, yours faithfully,
H. H. TIDSWELL, M.R.C.S. Eng., L R.C.P. Lond.

Torquay, March 19th, 1908.

MEDICAL MATTERS IN BASUTOLAND.

THE Colonial Office publishes the report of the principal medical officer, Mr. Edward C. Long, for the year 1906–07, during which period, he states, the people have shown an increasing inclination to utilise the Government hospitals and dispensaries. There were no epidemics of any importance and, with the exception of a small outbreak at a village in the Quthing district, the territory has been quite free from small-pox. There are references to an increase of leprosy in two districts. Efforts to ascertain the real extent to which the disease prevails have been made. On three occasions every leper who could be traced was examined and the case recorded. The first leprosy investigation was viewed with suspicion by the natives and doubtless many cases were concealed. The second count, made in 1902, was more successful and most of the cases were then under observation. In 1906 a third investigation was carried out and a special report thereon is in course of preparation. The numbers showed an increase over those observed in 1900 but the increase, after making allowance for cases which probably existed but were not observed on that occasion, was not sufficient to cause the disease to be regarded as a serious menace. The natives now fully realise its contagious nature and voluntarily segregate their lepers. The experiment of forming a leper colony, which is being tried by Chief Jonothan in the Leribe district, deserves encouragement. Mr. Long insists on the necessity of increasing the medical staff and the hospital accommodation of the colony. He also suggests that the time has arrived when the Basutoland Administration should have a public health department. Pending the organisation of such a department something might be done to make the Government reserves an object lesson in sanitary efficiency. Mr. Long adds: "I have lectured for the last two years on public health and sanitation to the native teachers at their vacation course. Unless the principles taught in these lectures are exemplified in practice and the practice enforced on the Government reserves we cannot look for much improvement in the habits of the people or the condition of their own villages."

COLOSSAL LIFE ASSURANCE FIGURES.

THE fifty-ninth annual report of the Prudential Assurance Company for the year ending Dec. 31st, 1907, states that the assets of the company are now over £68,000,000, of which sum in round figures £38,000,000 are assets of the ordinary branch and £30,000 000 are assets of the industrial branch. The total premiums received in the year amounted in round figures to over £11,000,000 and the claims of the year amounted to nearly £5,000,000. About £2,170,000 were also received in interest and rents. The expenses of management, commissions, and salaries amount to about £3,000,000, there being nearly 17,000 agents collecting weekly premiums. The total number of policies in force at the end of the year was 18,303,041. The directors regret the death of Dr. Robert Barnes who had been connected with the company from its foundation and had been a director for 23 years.

THE CAPSULOID COMPANY, LIMITED.

WE learn from our correspondents that the Capsuloid Company is now circularising medical men with the statement that many physicians have discovered the effect of "Capsuloids" upon the hair, the statement being meant to convey a suggestion that there are medical men who believe that the internal use of "Capsuloids" will prevent or remedy baldness. The last line of the circular respectfully calls the attention of the medical man to whom it is addressed to an analysis of "Capsuloids" which appeared in THE LANCET of August 11th, 1900. In this analysis we stated that a preparation which had been submitted to us contained a certain amount of iron in a certain form, and made no mention whatever of the possible use of "Capsuloids" in the treatment of baldness. The Capsuloid Company, Limited, however, diffused advertisements widely the significance of which could only be that we had recommended "Capsuloids" for the treatment of baldness. The circular on which we are commenting, though carefully worded so as to escape protest, is intended to create the old false impression. The company is not one that any medical man should have any dealings with.

◆

W.—We can hardly believe that any dentist ever gave such advice. It is dangerous not to remove false teeth on going to bed, while it is also insanitary and dirty.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*The Court Journal, Portsmouth Evening News, Lancashire Post, Daily Chronicle, Daily Mirror, Daily Graphic, Western Chronicle, Hereford Times, Wimbledon Gazette, Motor Car Journal, Liverpool Daily Post, Liverpool Daily Courier, Cardiff Times, Ely Gazette, Alnwick Express, St. James's Budget, Christchurch Times, Scientific American, Literary Digest (New York), Broad Arrow, Coventry Times, Edinburgh Evening News, &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (31st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (1st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.)

FRIDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2 30 P.M.), St. Peter's (2 P.M.).

SATURDAY (4th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. Jobson Horne, H. S. Barwell): at 5 P.M.

Cases and Specimens:

Dr. Jas. Donelan: (1) Case of marked Nasal Obstruction resulting from Neglected Adenoids; (2) Case of Nasal Obstruction with Deflected Septum.

Dr. StClair Thomson: Two Radiographs illustrating Value of X Rays in Sounding and Washing out the Frontal Sinus.

Dr. Scanes Spicer: Case of Intrinsic Neoplasm of Left Vocal Cord.

Dr. Dundas Grant: (1) Case of Thyro-lingual Fistula treated by Electrolysis and Excision; (2) Case of Chronic Frontal Sinusitis treated by Irrigation.

N.B.—Fellows of the Society are entitled to attend and speak at all Meetings.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith road, W.

FRIDAY.—8 P.M., Clinical Meeting.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY.—4.15 p.m., Discussion: (1) Does Chloroform Administration tend to the Production of Post-partum Hæmorrhage (opened by Dr. Bowie); (2) Anæsthetics in General Practice (opened by Mr. H. Wallace).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Sir James Sawyer: Points of Practice in Maladies of the Heart. (Lumleian Lectures).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M. Lecture:—Dr. C. O. Hawthorne: The Clinical Anatomy and Physiology of the Nervous System.

TUESDAY.—4 P.M., Dr. C. T. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Mr. H. Curtis: Some Interesting Cases of Cranial Surgery.

Glasgow, energetic and magnificent as indeed it was, had long enjoyed an unenviable reputation in this matter, but he did not think it had yet been brought home sufficiently to the minds of people in England and Scotland that the condition of the city of Dublin was twice as bad. The difficulty of dealing with the subject of the Bill arose from the poverty of Ireland. The towns had already borrowed pretty well up to their legal powers and the rates were oppressive. He therefore agreed that the financial proposals of the Bill would require consideration.

The motion for the second reading was ultimately agreed to without a division.

MONDAY, MARCH 23RD.

Tuberculosis in Ireland.

Mr. FFRENCH asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the New Ross urban district council passed resolutions to the effect that all cases of pulmonary consumption should be notified, that there should be more stringent and uniform measures for the regulation of milk and food supplies, that county councils should be enabled to erect and maintain hospitals, sanatoria, and dispensaries for the treatment of consumption, and that there should be a system of medical inspection of schools and school children; and whether he could hold out any hope of legislation in the direction indicated.—Mr. BIRRELL answered: I have received several resolutions on this subject. The Tuberculosis Prevention (Ireland) Bill which I am to introduce will contain a clause providing for the compulsory notification of tuberculosis and will also deal with the official supervision of dairies and the sale of food. As to the medical inspection of schools I would refer to the answer given to the honourable Member for South Down on Feb. 26th.

TUESDAY, MARCH 24TH.

Lead Poisoning.

Mr. ALDEN asked the Secretary of State for the Home Department whether he was aware that during the months of January and February of this year there were 17 cases of lead poisoning in the china and earthenware industry, as against ten for the same two months of 1907; that seven out of the ten persons affected by lead poisoning during the month of February this year were females; whether he could inform the House as to the number of china and earthenware factories represented by these cases; and how many of these cases had resulted in death.—Mr. GLADSTONE replied: The figures quoted by my honourable friend are correct. The 17 cases occurred in 14 factories and one of them was fatal. I am appointing a committee to make a further inquiry with regard to lead poisoning in this industry.

The Children's Bill.

The LORD ADVOCATE (Mr. SHAW) moved the second reading of the Children's Bill. He explained its provisions, which have already been indicated in THE LANCET. The Bill, he mentioned, dealt with the overlying of children and the figures relating to this evil were of an appalling character. A part of the Bill which might cause a little trouble was the portion which related to juvenile smoking. He confessed that when he first read the clauses he thought that the Government was going somewhat far. He had now gone fully into the records of the investigations conducted under the authority of the Crown and he found that the evil was of a most serious kind. The report of the Royal Commission on Physical Training showed that tobacco smoking before maturity was reached had a most prejudicial effect upon physical development. This evil could not be too strongly denounced. The Government had done something to meet it in the Bill and he hoped that the House would assent to the clause dealing with it.

Mr. AKERS DOUGLAS, as Home Secretary in the last Government, expressed himself as in general sympathy with the Bill.

In the course of the subsequent debate, Mr. RAWLINSON criticised the clauses relating to the penalties proposed to be imposed in cases where children were burnt when left with access to unguarded fires and also in cases of the overlying of infants. The House ought not to make an act a criminal act unless the person doing it had a criminal intention. He also criticised the machinery of the clauses dealing with juvenile smoking.

Mr. H. SAMUEL, Under Secretary of State for the Home Department, defended the Bill. Public opinion generally approved of the clauses relating to the deaths of children from unguarded fires and from overlying. The Government would be very sorry to give up these clauses. As to juvenile smoking, he defended the provisions of the Bill, and although no law might suppress the evil finally, still it was necessary for the discipline of the State to step in where that of the home was absent. He firmly believed that the provisions of the Bill would do much to put down a practice which had been condemned by medical men.

The debate was adjourned.

WEDNESDAY, MARCH 25TH.

Medical Inspection of School Children in Ireland.

Mr. JOHN REDMOND asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to a statement recently made by the President of the Board of Education to the effect that the Education Department were prepared to recommend to the Treasury that provision should be made in the coming financial year for the medical inspection of children attending schools, and that this provision should be made in the form of a special grant; and whether he intended to take steps to have a similar procedure followed and a similar grant made in connexion with medical inspection of schools in Ireland, and more especially with regard to the medical inspection of the eyesight of children.—Mr. BIRRELL replied: My right honourable friend the President of the Board of Education informs me that the newspaper report to which the honourable gentleman evidently refers contains a very material mistake. My right honourable friend did not say that he was prepared to make the recommendation in question to the Treasury. What he said was that he was asked to make that recommendation, and the sense of his reply is shown in a subsequent passage of his speech in which he asked the deputation not to press him to go to the Chancellor of the Exchequer for the ensuing year, for in the first place he thought it would be a mistake to introduce any special grant at a moment when they were anxious to get rid of special grants, and secondly he feared that the Chancellor of the Exchequer would not be able to meet their demands at present having regard to the existing claims that were made upon him.

BOOKS, ETC., RECEIVED.

APPLETON, SIDNEY, London.

Modern Clinical Medicine. *Diseases of the Nervous System.* Edited by Archibald Church, M.D., Professor of Nervous and Mental Diseases and Medical Jurisprudence, North-western University Medical Department, Chicago, Illinois. Third edition. Price 25*s*. net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BAYLEY, ERIC, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Co-Divisional Surgeon to Police of G Division stationed at City-road, London.

COPE, V. ZACHARY, M.D., B.S. Lond., has been appointed Surgical Registrar to the London Temperance Hospital.

EDWARDS, ALBERT DAVIES, M.B., B.S. Lond., D.P.H. Edin., has been appointed Assistant Medical Officer and Assistant Schools Medical Officer by the Newport (Mon.) Education Committee.

EVANS, THOMAS, M.B. Lond., has been appointed a Medical Inspector of School Children for the County of Glamorgan.

GILES, JAMES A., M.B., B.S. Durh., has been appointed Assistant Medical Officer of Health of the County Borough of Devonport.

GRIMBLY, RICHARD HENRY, M.R.C.S., L.S.A., has been appointed Medical Officer for the Ipplepen District by the Newton Abbot (Devon) Board of Guardians.

HOWARD, RUSSELL, M.S. Lond., F.R.C.S. Eng., has been appointed Curator of the Museum of the London Hospital Medical College.

JONES, EDITH ANNE, M.B., B.S. Lond., has been appointed a Medical Inspector of School Children for the County of Glamorgan.

LANYON, GEORGE EDWARD, M.B., C.M. Edin., has been appointed Medical Officer of Health for the Falmouth and Truro Port Sanitary Authority.

MAGAREY, RUPERT E., M.B., B.S. Adelaide, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

MILL, G. ROBERTSON, M.D. Edin., has been appointed Honorary Anæsthetist to the Liverpool Dental Hospital.

RICHMOND, D. S., M.B., Ch.B. Glasg., has been appointed Medical Officer and Vaccinator to the Parish of Dalry, Kirkcudbrightshire.

SPICER, R. H. SCANES, has been appointed Honorary Consulting Surgeon for Throat Diseases at St. Mary's Hospital.

Communications, Letters, &c., have been received from—

A.—Monsieur F. Alcan, Paris; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; A. T.; Ayr District Asylum, Medical Superintendent of; Mr. E. Arnold, Lond.; Mr. R. J. Albery, Lond.; Dr. F. R. v. Arlt, Vienna.

B.—Dr. A. G. Bateman, Lond.; Mr. Shirley E. Blacker, Lond.; Bureau of Public Health and Marine-Hospital Service, Washington, D.C.; Berrow's Worcester *Journal Co., Manager of*; Mr. F. E. Bennett, Margate; *Birmingham and Midland Eye Hospital*, Secretary of; Messrs. *Foster Brown and Co.*, Montreal; Mr. W. Bryce, Edinburgh; Mr. C. Birchall, Liverpool; Surgeon-Captain Robert H. Bakewell, Onehunga, New Zealand; Dr. Cesare Ballabene, Berlin; Birmingham and Midland Free Hospital for Sick Children, Secretary of; Messrs. J. B. Brooks and Co., Birmingham; Mr. F. Burgis, Buenos Aires; Mr. F. A. Brockhaus, *Lond.*; *Messrs.* Burgoyne, Burbidges, and Co., Lond.; *British Oxygen Co., Lond.*; Messrs. An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements *on* pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements *or Subscriptions* should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

Notes, Short Comments, and Answers to Correspondents.

THE TITLE OF DOCTOR.

IN the course of an action recently heard in the Probate, Divorce, and Admiralty Division, a barrister appears to have addressed the following questions to a medical man:—

Q. What are your qualifications, Sir?
A. L.S.A. Lond., and also an M.A. Cambridge.
Q. Are you a doctor, Sir?
A. Most certainly.

The barrister, who was cross-examining, probably meant to be offensive, in which connexion it may be remembered that a member of the Bar recently said to a Licentiate of the Society of Apothecaries whose evidence he wished to discredit, "You hold the lowest degree in medicine." But we are not concerned so much with the barrister's manners as with the inability of an educated man to see that the title of doctor has two significances. Academically it belongs only to those who possess a doctorate granted by a recognised University; popularly it belongs to all medical men. Having asked the witness what his qualifications were, the further question was unnecessary unless the barrister wished to involve the witness in some dispute the outcome of which might be that the jury would fancy that the witness was claiming some title to which he had no right. We think that members of the Bar might master the differences between a degree and diploma and between the formal and colloquial usage of the title of doctor, while they might also remember that medical men do not possess their statutory right to give medical evidence because they possess this or that qualification, but because their names are on the Medical Register, after pursuing a course of studies which is satisfactory to the General Medical Council.

A COINCIDENCE IN INVENTION.

To the Editor of THE LANCET.

SIR,—In your issue of March 14th there appears a letter from Mr. H. R. Davies under the above heading. It refers to the similarity existing between a pessary invented by him in 1900 and one described by me in your issue of March 7th. He is correct in saying that they are to all intents and purposes identical, and indeed, so far as I can judge from the illustrations of his instrument, the only distinctive feature is that his instrument is composed of vulcanite throughout, whereas mine consists of a steel stem and bars supporting either an ordinary watch-spring or vulcanite ring, the object in this being that the more perishable ring portion may be replaced as frequently as required without the necessity of purchasing an entire new instrument.

I may add that I was in total ignorance of the existence of Mr. Davies's pessary when I had mine made, and also that I consulted several surgical instrument catalogues in search of an adequate pessary for the class of case I had to treat, but without finding any of the kind I required.

If I had known of Mr. Davies's pessary I should certainly have used it, and I congratulate him sincerely on the invention of his instrument.

I am, Sir, yours faithfully,
SEYMOUR STRITCH,
The Governor, the Apothecaries' Hall, Ireland.
Dublin, March 23rd, 1908.

THE FUTURE OF THE TELEPHONE SERVICE.

A QUESTION which is now exercising the public mind is that of the future of the telephone service, and although the "commercial" community is most directly interested, because the points at issue do not materially affect the medical profession, at the same time the use of the telephone is becoming so universal among medical men that many of our readers ought to know the pros and cons of the question. The administrators of the telephone services have in contemplation the doing away entirely with the "flat-rate" system—the payment of a fixed sum for an unlimited number of calls, and the substitution wholly of the "message-rate" system—the payment of a fixed sum for each call made. This latter system was more or less introduced some few years ago when the Post Office service was inaugurated. The authorities now claim that the enormous increase in the number of telephones compels them to do away with the "flat-rate" system, so as to secure the efficient working of the service, in the interests of telephone users themselves. Much opposition is being manifested towards the proposed change by chambers of commerce and large commercial houses on the ground that such a change would be a tax on trade and commerce, but the matter hardly strikes us in this way, while the "flat-rate" system is certainly a tax on the time and temper of the public. Anyone who has experience of "calling up" any of the large trading concerns knows only too well how persistently the reply is "line engaged," the line being blocked with outward calls. This nuisance is becoming increasingly grievous and is brought about by the systematic overloading of their lines by short-sighted users who will not put in the additional lines which they clearly require. Fortunately, most of the large wholesale houses with which the medical profession have to do business have long since recognised the futility of overloading their lines and have doubled and trebled them, one large firm of manufacturing chemists in particular having six lines running into their City premises. This is as it should be, because it makes for an efficient service, and an efficient service must in the long run be the least expensive service. Above all, it practically eliminates the "engaged" call—the worst feature of the present service. For the great majority of medical men—we should think for all of them—the "message-rate" system is sufficient, and whilst its cost is at present much too high it is obviously cheaper for them than the "flat-rate" system. We incline to the opinion that the "message-rate" system, fixed on an equitable basis, which should not exceed £3 3s. for the minimum service, is the better system: it is a system by which the user pays in proportion to service rendered, while it prevents the abuse under which some users pay an annual subscription greater than it should be because other users on a "flat-rate" or unlimited system do not pay their due share.

EXCESSIVE SMOKING BY A YOUTH.

To the Editor of THE LANCET.

SIR,—To break the cigarette habit in a youth there is nothing better than peppermint drops. He cannot smoke with a "bull's-eye" in his mouth, and even for some time after it is dissolved tobacco will not blend kindly with the taste that remains. Socially the cure may seem worse than the disease, but from a medical point of view the sucking of peppermints is far less hurtful. A common "bull's-eye" will prevent smoking for nearly an hour, so the amount of sweets used need not be great. It would be a good plan to insist upon the youth who will smoke making his own cigarettes without the aid of a machine. Few will smoke to excess if they have to make their own cigarettes.

I am, Sir, yours faithfully,
Silverton, March 24th, 1908. O. CLAYTON JONES.

A TURKISH PERMIT FOR BURIAL 100 YEARS AGO.

"THE following," writes Dr. J. Cropper of Chepstow, "was given me as a literal translation of a Turkish permit for burial. It is 100 years old and was translated for me by an Arab medical man (qualified in Beyrout) as a specimen of the treatment meted out to the 'dog of a Christian' in the old days when it was not permitted to such to carry a walking stick or to walk to the right of a Moslem when passing in the street. The growth of Western ideas and not less the influence of Christian medical missions has altered much of this and the cursing of Christians is now chiefly left to children and small boys who still often 'take the change' out of travellers."

[TRANSLATION.]

From the Most High Court, &c., &c.

Seeing that a petition has been presented by the Bishop of the Infidels on behalf of the deceased [here follows his name], and as he has perished and we know that if he is left unburied his smell will pollute the air breathed by the true Believers, we give hereby permission for him to be buried in their well-known dung hill and to go to his company in Hell.

[Here follow the seals of the signatories.]

"PINOMED" HANDKERCHIEFS.

THESE handkerchiefs are composed of two sheets of fine tissue paper interleaved with a very thin layer of absorbent wool which has been scented with oil of pine. They are very soft and pliable and can imbibe a considerable amount of moisture before becoming limp. They are intended to be destroyed when no longer serviceable and in this respect have an obvious sanitary advantage over cambric handkerchiefs in cases of pulmonary disease or when there is ulceration of the lips, nose, or mouth. They measure about 14 by 16 inches and may be obtained from Mr. Clement A. Graham, 55, Leigham Court-road, Streatham Hill, London, S.W.

CAUSES OF THROAT AND CHEST CATARRH IN CHILDREN.

To the Editor of THE LANCET.

SIR,—I am frequently coming across children suffering from throat and chest affections due to cold caught at school. I believe it is the custom in all schoolrooms in this town to keep the windows open all weathers. This is a crude and barbarous method of ventilating a schoolroom. About half the children who attend school appear to be always suffering from the effects of cold, having chronic rhinitis. About 15 months ago a patient of mine, a delicate boy, aged six years, had several severe colds on the chest in one winter while attending school. I discovered that he caught his colds at school and I ordered him to be kept at home the last winter. The result is most satisfactory; he has not once suffered in his health. One of his former attacks turned to croup and he was so ill one night that I was sent for and found him in a state of great exhaustion. No doubt the schools are responsible for many cases of adenoids.

Another fruitful source of these ailments is due to insufficient clothing and defective boots, not always on account of poverty. Some mothers imagine a boy of six is sufficiently clothed if he wears a thin jacket and pair of knicks of serge, with a shirt of flannelette beneath; the knees and legs are quite exposed. Half the children wear boots or shoes which are not waterproof; they are therefore worse off than barefooted children, because bare feet soon dry, but feet in waterlogged boots must be wet and cold until the boots are removed, by which time the blood is chilled and illness established. I hope other as their beast of burden, for riding purposes, and for war. They were unacquainted with camels, horses, and mules. They had no religious creed. Their food was millet, honey, and the flesh of animals. The Mahomedans carried on traffic with them for ivory, gold, and skins. Wild elephants were numerous and were killed with darts. In 1330 a description of the same districts was given by Ibn Batuta, a native of Tangier. From a little before this time there is in the Chronicle of the Rulers of Kilwa a fairly complete history of this part of the coast of Africa. In 1498 Vasco da Gama begins the European history of the district.

There is a break in the historical knowledge of the western side of Central Africa from the second to the fourteenth centuries, when Norman adventurers sailed past the Canary Archipelago and Cape Verde to the land of the blacks. The Genoese appear to have had some knowledge of the coast as far as the Bight of Biafra, if we can judge from a map dated 1351 in the Medician library at Florence and published by the Hakluyt Society. This map also gives some of the results of the exploration of the Central Soudan by the Arabs, for the upper course of the Niger is delineated and there is an outline of Lake Chad. In the fifteenth century the Portuguese pushed forward several expeditions. De Sintra reached the Liberian coast and gives a description of the natives who came off in canoes, "quite naked," carrying pointed spears, darts, javelins, bows, and here and there a shield of leather. Their ears and noses were pierced and their teeth were sharpened to a point. One of the natives was brought back to Lisbon. In 1484 Diago Cam reached the mouth of the Congo, and the next year Cape Cross.

The first recorded contact of Europeans with the short-statured tribes of South Africa was in 1486 when Bartholomew Dias having passed the Cape landed in Mossel Bay. The inhabitants, astonished at the apparition coming over the sea, fled inland and all that was learnt was that they had numerous droves of domestic cattle. In 1497 Vasco da Gama landed at St. Helena Bay and met with a party of natives, short in stature, ill favoured in countenance, and dark in colour. They used many gestures in speaking, their dress was a kaross of skin, and their food wild roots and seals and whales washed ashore by the tide. They had no domestic animal but the ox. Their weapons were shafts of wood pointed with bone or horn. This description would apply to either beachranging Hottentots or Bushmen but the weapons are those associated with the former. In the same year at Mossel Bay da Gama met a number of Hottentots riding on pack oxen and also possessing sheep. In 1510 Don Francisco d'Almeida and a party landed at Table Bay and were involved in a quarrel with the Hottentots. An expedition of 150 men was landed and attacked the kraal. The Hottentots, 170 in number, replied with stones and fire-hardened wooden assegais, using their riding cattle as shields. The Portuguese were utterly defeated, 65 being killed, including the retiring Viceroy of India. Thenceforward there is an ample written history of South Africa. It was not until some time after the Dutch occupation that it was realised that there were at least two peoples in the country who waged bitter war on one another, the Bushmen and the Hottentots.

In 1625 Purchas published the first modern account of the dwarf races of tropical Africa in "The Strange Adventures of Andrew Battell of Leigh in Essex, sent by the Portugals, prisoner to Angola, who lived there and in the adjoining regions near 18 years (1589–1607)." Battell said :—

> To the north-east of the *Mani-Kesock* are a kind of little people called Matimbas; which are no bigger than Boyes of twelve yeares old, but very thicke, and live only upon flesh, which they kill in the woods with their bows and darts. They pay tribute to Mani Kesock, and bring all their elephants' teeth and tayles to him. They will not enter into any of the Maramba's houses, nor will they suffer any to come where they dwell. And if by chance any Marambа or people of Longo pass where they dwell, they will forsake that place and go to another. The women carry Bows and Arrows as well as the men. And one of these will walk in the woods alone and kill the Pongos with their poisoned arrows.

Battell's statements have been confirmed by du Chaillu and others and there is now abundant evidence of the existence of short tribes in the Ogowe and Camma districts.

The verification of the statements of early authors as to pygmy tribes in Central Africa was made by Schweinfurth in the Niam Niam country, subsequently by Emin Pasha, Stanley, Junker, and a host of others. Further south Wolf and Wissman proved their existence in the forests of the Kassai. Two distinct groups of the shorter peoples are now recognised, the Bushmen Hottentots of the Cape and the Negrillos of the Central African forests. These must be considered separately.

The Cape Bushmen are usually described as of a yellowish brown colour, short statured, with slightly broad heads, short black hair tightly twisted into small rolls or peppercorns. They possess little *or no beard*, *nose broad* and without prominence of the bridge, cheek bones projecting. Their jaws are usually said to be very protuberant, but this is relative and not actual, the appearance resulting from the flatness of the nose. The forehead is often bulging and the face straight. The coronoid process of the lower jaw is short and the sigmoid process is shallow. The stomach is pro*tuberant and the* back is exceedingly hollow. In spite of this great lordosis the lumbar vertebræ mounted alone without intervertebral discs actually curve forwards in a C curve, the posterior height of the centre of the lumbar vertebræ exceeding the anterior height. *They must, therefore,* be placed in the koilorachic division of Turner with the other pygmy peoples, the negroes and Australian aborigines. They are said to have greater powers than the average of twisting their bolas and to practise sitting down and shooting poisoned arrows at one another. *The Bushmen, who have now* disappeared from the Cape, were all nomadic hunters, whose weapons were the bow and poisoned arrow. Their habitations were caverns, *rock-shelters*, or merely mats spread over branches. *In conditions of extreme poverty they often used* only a screen of branches. They slept coiled up. Their only domestic animal was the dog. They wore little clothing and adorned themselves with necklets of beads made from the shells of ostrich eggs. They used rough stone implements and a characteristic rounded and perforated spherical stone into which was inserted a pointed stick used for digging purposes. They are described as having a very slight social organisation, but it must be remembered that they had been hunted outlaws for years before any investigations into their customs were seriously undertaken. Being only hunters they suffered very severely when their hunting grounds were occupied from the east by the Hottentots, from the west by the Bantu, and from the south by the Europeans. As the game was gradually driven away they were forced to make raids on the herds which took their place, and from the reprisals thus provoked were driven from being a quiet friendly folk to become marauders whose hand was against every man. No serious attempt was ever made by the successive governing bodies at the Cape to settle this people and those who had been gradually accustomed to a pastoral life by missionary efforts were constantly displaced as the farmers spread up country and forced to resume their old habits. The Bushmen developed singularly artistic taste and produced rock sculptures and paintings of a higher type than the taller tribes which recall the works of the early Stone Age in the Dordogne.

It seems probable that there were *two classes* of Bushmen, those of the plains and those of the mountains. The former were known as the Kraal Bushmen and so called because they built a sort of low round cairn in which they slept on the plain, never going into the fastnesses of the mountain, and Peringuey of the Cape Town Museum points out that it is this type of Bushman that still survives in the Kalahari. He shows that it is *probable that* the term Bushman comprises many unknown quantities and that it is certain that the Bush people of the central part of the colony did not understand the language of those to the North-east. *This might, however, be explained* by the conditions of life favouring the production of linguistic diversity.

Andersen[1] distinguishes four types of *Bushmen in the* Kalahari—the Cape Bushmen, some who are not racially Bushmen at all but Bantu people forced to adopt the Bushman mode of life, others are probably half-castes, and in addition he describes a lower *type* than has been met elsewhere. He says :—

> At *Narukus*, on the Nossop river, I came upon a family of Bushmen, ten in number, *of a* different *type* to those I had in my service and evidently of a lower class. They have no forehead; the wool on their heads comes close down to their eyes; projecting mouth; small *nose*; a sort of hair or wool all over the chest, arms, and legs; their eyes are small and restless. The tallest man did not exceed 4 feet 4 inches. Their skin was *of a* reddish-brown. A few old skins, broken ostrich eggs, and bows and arrows seemed all they possessed of worldly goods. *All were destitute of clothing.*

His Bushmen attendants repudiated the *idea that they* were of the same race as these newcomers, who, they said, were

MONDAY.—8 P.M., Dr. J. C. Thresh: The Milk Problem.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

characters resemble those of the negroes; their hair is frizzly, not in peppercorns; their complexion is, as a rule, lighter than the negro, but much darker than the Bushmen. Sir H. H. Johnston in the Semliki district distinguished two types, a light and a dark, and regards the lighter type as the purer. The M'Boulous of the Ogowé are described as of an earthy brown colour, the Obongo as dirty yellow coloured with hair tightly coiled in tufts. Watwas, on the bend of the Congo, were called by Stanley chocolate brown; Wolf described the Batwa as much lighter than the negro. The pygmies from the Ituri were very dark. Schweinfurth described his Akka as of the colour of slightly roasted coffee. The statures of the Negrillos show, as may be seen from the following table, a considerable range of variation, no doubt dependent on racial intermixture.

TABLE II.—*Giving the Statures of Negrillos.*

Race.	Male.				Female.			
	mm.		ft.	ins.	mm.		ft.	ins.
Akka	1360	=	4	5½	1260	=	4	1¾
Batwa	1300	=	4	3	—			
Vatua	1390	=	4	6½	—			
Ituri Pygmies	1375	=	4	6¼	1300	=	4	3
Bamlute	1450	=	4	9	1360	=	4	6½
Obongo	1370	=	4	6	1400	=	4	7
Akoa	1510	=	4	11½	1420	=	4	8

Individuals are sometimes found much *shorter*—e.g., in Emin Pashá's *entourage* was an Akka woman only 1165 millimetres in height (3 feet 10 inches.) The *hair is* generally described as frizzly or tufted. They are markedly prognathous and present extremely broad nasal orifices and everted lips. The head form varies but is usually sub-brachycephalic, differing therein from the negro peoples. The highest index, and therefore the broadest head, recorded is 87 in an Akoa. I have collected the measurements of 27 pygmies from the Congo Nile watershed and find the average index in 21 males to be 78·9 with a standard deviation of 2·7240, and in six females 80·5 with a standard deviation of 2·3052. These figures may be contrasted with those of the Strandloopers who presented an average index for the male skull of 77·1; as this would correspond to 78–79 in the living it would thus appear that there is no appreciable difference. The general proportions of the body are, as pointed out by Flower, those of the taller peoples, so that they in no wise resemble the dwarfs of other races. The chief characteristics are the shortness of the trunk and the length of the upper limbs. The prognathism, absence of flattening of the face, and greater prominence of the brow ridges seem to distinguish them from the Bushmen, from whom they also differ in the absence of the tablier and of steatopygia, though it is extremely doubtful whether these latter features can be looked on as racial, in view of their far from universal occurrence among the race so characterised.

When models of examples of the two races are looked at side by side differences are very apparent; when average measurements and deviation are studied, resemblances become evident save as regards prognathism. It is interesting that the skull form of the older Bushmen should more closely resemble that of the Negrillos and that the purer type of the latter should be lighter in colour, while the general canon of proportions is very similar in the two cases. The Negrillos appear to show a greater variation in all characters and are probably a far more mixed people and the differences they show from the dwarf races of the south are those which might have been derived from negro intermixture. Yet tempting and even probable as is the hypothesis that they represent separate remains of the primitive peoples of South Equatorial Africa before the invasion of the negro and the subsequent contact metamorphism, it must for the present be regarded as at the best unproven. Further material for the investigation of either or both of these groups is urgently needed and would help to solve one of the most interesting problems of the world's history.

AT a meeting of the Incorporated Society of Medical Officers of Health to be held on April 10th Dr. Francis E. Fremantle, medical officer of health of the county of Hertford, will read a paper upon the Garden City, Rural Housing, and the Government.

ON

TUBERCULOSIS OF THE KIDNEY,

AND

MALIGNANT DISEASE OF THE CÆCUM.

Delivered before the Medical Society of London on Feb. 3rd and 17th, and March 2nd, 1903.

BY CHARTERS J. SYMONDS, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO, AND JOINT LECTURER ON SURGERY AT, GUY'S HOSPITAL.

LECTURE III.[1]

Delivered on March 2nd.

MALIGNANT DISEASE OF THE CÆCUM.

MR. PRESIDENT AND GENTLEMEN,—*Looking upon operative removal as the only remedy for malignant disease early* recognition becomes of the first importance. Everyone *recognises that it is sometimes difficult, and often impossible,* to estimate accurately the nature of abdominal swellings without opening the cavity. There is a tendency on this account to two evils—first, to postpone operation till the appearance of certain well-known signs of disease, and so lose the most valuable moment for extirpation of malignant growths; and secondly, to lose confidence in the value of *those signs* which point to inoperable disease and to explore every case. To wait for signs of obstruction in intestinal cancer, or again for signs of cachexia, is to ignore the value of the early characters of malignant disease. Unfortunately, cancer is a painless malady for many months and in the *intestine it is* not until some degree of obstruction occurs, or a tumour makes its appearance, that it attracts attention. It is therefore important to remember that when these signs arise the disease has been in existence a long time and immediate operation is advisable—if advisable at all. In this regard the rectum may be used for illustration, where *we so frequently find disease, already inoperable, with a history* that must represent but a fraction of the duration of the disease. *As regards cancer of the large intestine, excluding the* rectum, with which this lecture specially deals to-night, the operative success is most satisfactory, even extensive removal being well borne. Again, *lymphatic infection is* slow to occur while extension to the peritoneum and other organs is long delayed, except in a few special instances. *The immunity conferred is also satisfactory and will improve* as the cases come earlier for operation.

No one must speak lightly of resection of the intestine, especially when, as in most of the suitable cases, the health is good and the vigour and working power are undiminished, A disaster will cut short a life with a year or more of satisfactory existence and useful performance. Resection, however, when the contents are not septic, requires but the requisite knowledge and dexterity to attain success—knowledge when to proceed with, when to abandon, an operation; what limits to set to the undertaking; a patience that will not fail when further but removeable infiltration is found after all had apparently been removed, and that will examine and see that no weak point in the defence has been left unprotected. The necessary dexterity in preparing and suturing the bowel is easily acquired, and then, if so conducted as to be made almost an extraperitoneal operation and all tugging on the mesentery and nerve plexuses avoided, the danger, when the disease is a limited one, is reduced to a minimum. Very different is it when more extensive operations are carried out, especially when having embarked on an apparently straightforward piece of work, unexpected difficulties are encountered that must be surmounted just because the operation has gone too far to be abandoned. Increased experience enables us to avoid attempting extirpation when such difficulties are likely to arise, and yet if we take too limited a view and shrink from accepting a considerable risk relievable conditions will be left.

The first part of the large intestine is particularly suitable for resection on account of the length of the mesentery, the ease with which it can be handled, and the satisfactory condition in which the parts can be left, for by joining the ileum

---

The Hunterian Lectures

ON

THE PYGMY AND NEGRO RACES OF AFRICA.

Delivered before the Royal College of Surgeons of England on March 2nd, 4th, and 6th, 1908,

BY F. C. SHRUBSALL, M.A., M.D. CANTAB., M.R.C.P. LOND., M.R.C.S. ENG.,

RESIDENT OFFICER OF THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, LONDON, S.W.

LECTURE I.

Delivered on March 2nd.

MR. PRESIDENT AND GENTLEMEN,—The continent of Africa may be divided from the ethnic standpoint into two distinct sections—a northern, inhabited by white races; and a southern, inhabited by negroes and pygmies. The line of separation lies nearly along the tenth parallel of north latitude save for an extension northward of the negro zone in the Nile valley and southwards of races with a large white element to the equator along the borders of the Red Sea and the Indian Ocean. While there are abundant materials for the reconstruction of the early history of the northern section and especially of the Nile valley, little or nothing is known of the southern area until the date of the first European explorations.

From the paintings and sculptures in the various tombs and temples in the Nile valley it is clear that the Egyptians were well acquainted with the negro tribes of the Soudan. The Egyptians had a definite and constant communication both by sea and overland with the "Land of Punt," which probably embraced the modern Abyssinia and Somaliland, and had some idea of the geographical features of these districts.

Since the sculpture on the tombs of Ti and Ptahhotep, referred to the fifth dynasty and an estimated date of 3300 B.C., represent pygmy forms undoubtedly in some measure resembling the races now found in equatorial Africa, they must have been acquainted with their existence on the upper waters of the White Nile. Inscriptions of this period state that beyond Puanit (? Punt) the land was occupied by the Dangas, a tribe of half savage dwarfs. The word Danga still occurs in modern maps denoting a point on the borders of Darfur and Niam Niam. From somewhere in this region a pygmy was sent to King Assi (3300 B.C.) by one of his officers. Keane, quoting Schiparelli, shows that some 70 years later Pepi II. of the sixth dynasty sent an officer "to bring back a pygmy alive and in good health" from the land of great trees away to the south.

Karl Peters has suggested that the Egyptians may have penetrated as far as South Africa, on the basis of a statuette bearing the cartouche of Thotmes III. (1450 B.C.) found in Southern Rhodesia. It is, however, more likely that the statuette was dropped there by chance in recent years and it is by no means certain that it is of genuine ancient Egyptian origin. About 600 B.C. Neku, the son of Psametik I. of the twenty-sixth dynasty, sent an expedition of Phœnicians to sail down the Red Sea and along the coast to the land of Punt. According to tradition recorded by Herodotus, this expedition circumnavigated Africa, reaching the Mediterranean by the Straits of Gibraltar. That author records that the expedition was actually ordered to leave the Red Sea and to return by the Pillars of Hercules. He also states that the expedition took three years during which from time to time they landed, sowed corn, and having reaped the crop resumed their journey. While sailing round Libya they had the sun on their right hand, which is the strongest confirmatory evidence of the truth of the narrative. About this period the Phœnicians from Carthage had founded settlements along the Western Mediterranean and the Atlantic coast of North Africa. About 520 B C occurred the celebrated expedition of Hanno who, having revictualled the Carthaginian colonies on the western coast of Morocco, founded a fresh settlement on Kerne Island in the Rio del Oro inlet and then proceeded south past the Senegal and Cape Verde. Sir H. H. Johnston concludes that this expedition reached Sherbro Island at the western border of Liberia; others conclude that its termination was the mouth of the Ogowé river. On the island at the end of their journey the travellers captured wild hairy men. The name given to these in the Greek translation from the Punic was "gorilla."

In the fourth book of Herodotus there is an account of an expedition made somewhat later by Sataspes who was ordered to circumnavigate Africa. He passed Cape Soloecis and journeyed south for many months until he said his ship refused to travel farther. At the farthest point he reached the coastlands are described as occupied by a dwarfish race who wore a dress made from the palm-tree. These people, whenever the expedition landed, abandoned their homes and fled away inland, although the men did them no harm and only entered their cities and took some of their cattle. As confirmatory evidence it may be noted that after passing the equator the winds and currents would have been against this expedition while favouring the passage from south to north. The mention of a dress made of vegetable fabric agrees with the modern description of the peoples on the west coast north of the Ogowé river.

Herodotus himself visited Egypt (*circa* 457 B.C.) and journeyed up the Nile as far as the first cataract. He learnt that there was a great city of the Ethiopians in the bend of the Nile at Meroe, but beyond that nothing certain was known. In Book III. he, however, records that Clearchus, king of the Ammonians, gave information imparted to himself by certain Nasomonians, a Libyan race who occupy the Syrtis. Certain of their young men crossed the Libyan desert from east to west. After journeying many days over a wide extent of sand they came at last to a plain where they observed trees growing. While engaged in gathering fruit there came upon them dwarfish men under the middle height who seized them and carried them off. They were led across extensive marshes and finally came to a town where all the men were of the height of their conductors and black complexioned. A great river flowed by the town running from west to east and containing crocodiles. This river is usually identified as the Niger, but Professor Elliott Smith in his notes on African pygmies suggests the Sobat, in which case the town must have been in a bend of the river as its main course is east to west. The important feature is that the pygmies are once more brought to notice in Central Africa and at a point far to the north of their present geographical distribution. The Greek geographer Eratosthenes sketched the course of the Nile and its Abyssinian affluents and hints at the source of the river from great lakes. Roman expeditions explored the Nile as far as the marshes above Fashoda, coming in contact with the negroes of this district and also reached the country around Lake Chad, which they found to abound with rhinoceroses.

The first clear map of the district is given by Claudius Ptolemaeus (so-called Ptolemy) 150 A.D. He quotes in full an account given by Marinus of Tyre of the journey of a Greek merchant Diogenes. This man is said to have landed at Rhaptum on the East African coast, to have travelled inland for 25 days' journey, and to have arrived in the vicinity of the two great lakes and the snowy range of mountains whence the Nile draws its twin sources. It is probable that he got his information from Arabs. He says that the mountains were named from their brilliance the "Mountains of the Moon." He was told that the Nile united its twin head streams at a point to the north of these two great lakes and then flowed through marshes until it joined the river of Abyssinia. Ptolemy's map places the mountains actually in Unyamwezi, which is erroneous. As Unyamwezi means "land of the moon" it is possible that this name was transferred to the mountains seen after passing through that country. From this time on knowledge of Central Africa gradually dwindles, though after the Arab invasions some rumours of the existence of the lake country reached mediæval Europe. The former accounts were disputed and disbelieved for over 1700 years until confirmed by the discoveries of Sir Henry Stanley.

The exploration of the Eastern coasts of Africa was carried on by the Arabs and Persians who established settlements there during the tenth century of our era. In the great work of the Arabian traveller El-Macoudi, completed A.D. 943, a description of the coast and natives is given. El-Macoudi refers to the negroes or Zendj as inhabiting the land as far south as the country of Sofala where they bordered on the Wak Wak or Bushmen. The Zendj were under a paramount ruler with the title of Waklimi. Among them were some with sharpened teeth who were cannibals. They used the ox simple; and secondly, because he could not decide what it was. The disadvantage of not combining personally in such a consultation is seen in the sequel. Expectant treatment was followed; the lump increased; and at the end of six months I was called to see the lady who was in great distress from abdominal pain. There was now a large apparently inoperable mass, with dilatation and hypertrophy of the small intestine. The day before there had been an attack suggesting perforation and I learnt that for some time all the symptoms had grown worse, especially those of chronic intestinal obstruction. Short-circuiting seemed now the only relief to be afforded, and with this object the abdomen was opened in the linea semilunaris. The end of the ileum was difficult to discover on account of adhesion to the large mass of growth. In the search the whole mass was raised up and though at first sight inoperable extirpation now seemed possible. There were several mesenteric glands, some close to the spine, but there were no secondary deposits in the liver or parietal peritoneum. Looking to the inevitable and early termination of such a condition I decided to extirpate the disease. It was an extensive operation as a good deal of the mesentery had to be removed, but was completed without the patient exhibiting any particular distress during the performance. The shock following was quite moderate and the outlook at the time appeared to justify the decision to proceed. The colon was closed and the end of the ileum united to its side by a Murphy's button. She recovered from the shock which was necessarily severe, but in a few hours uncontrollable vomiting set in. The material vomited contained blood from the first and this black character persisted till her death on the third day. No doubt the interference with the sympathetic nerves involved in so extensive a removal of the mesentery proved too much for the patient and determined the hæmatemesis and reflex vomiting. At the same time she was young and had, notwithstanding the duration and extent of the disease, preserved much energy and cheerfulness. There was besides no cachexia and the wasting might well be explained by the diminished ability to take food on account of the colic.

It is difficult to define the limit to which one may go in dealing with extensive cases, as there are so many on the borderland. This one was, no doubt, as it proved, in the inoperable area. Still, each must find out for himself when to stop an operation and not be influenced by the question of percentage of success. That must never enter into one's calculations; the welfare of the patient must be, and must be alone, the first and last consideration. In this case there was but one inevitable termination and that a speedy one. The conversion of what was intended to be an anastomosis of the ileum with the colon into an extensive resection was made when it was found that the mass could be raised from the iliac fossa. If operated upon as advised when seen in June what might not have been the result?

Where the posterior wall is the seat of disease, or where the growth is of a diffused type, the tumour will not be so defined, and here the symptoms of obstruction will come on later. Some of these diffused cases give rise to much difficulty in diagnosis, especially when the cæcum is abnormally moveable. A good example is that of Case 3.

CASE 3. *Diffused cancer of the cæcum; resection; recovery.*—A vigorous, active, spare man, aged 75 years, was seen in consultation with Mr. Donald W. Smallpiece for abdominal pain, wasting, and indigestion, and a doubtful swelling in the right ilio-lumbar region. For some time the symptoms had existed and the colic had been felt all over the abdomen. Dr. J. F. Goodhart, who had seen this patient, has been good enough to give me a summary of the notes he made when he saw the patient a few months before the visit to me. From the pain and wasting malignant disease was suspected and this was strengthened by a resistance felt below the ribs on the right side. Three weeks later at a second visit this resistance was more marked and Dr. Goodhart thought it must be a gall-bladder containing a stone. He suggested that a surgical opinion should be taken but added, "I hesitate to advise operation at 74." Other opinions threw no further light upon the case. When I saw the patient some weeks had elapsed since the above note was made and we could then distinctly feel a well-defined mass in the ilio-lumbar region. On deep inspiration it came forward and could be pushed over to the umbilicus. When pressed from the front it slipped back with a rush into the loin. Irregular, flattened, only slightly nodular, moveable to an extreme degree, and painless, it felt more like a diffused thickening of the cæcum and colon than a localised new growth. The low position and these characters excluded a gall-bladder, but it might have been a loose and altered kidney. Now it transpired that some years before the patient had passed a renal calculus and it was quite possible that a sacculated relic of the kidney remained possessing unusual mobility. Covered by a colon and freely moveable, such a swelling as occurred in this case might be thus explained. I have seen such a kidney in the pelvis. The most likely diagnosis, looking to the situation, to the mobility, to the indigestion, and to the colic, was that of a growth of the cæcum interfering with the ileo-cæcal valve. The effect of past ulceration could not be excluded, especially as the patient had spent some time in tropical countries. Tuberculosis was considered, but the age of the patient, together with the mobility and his good health, were opposed to this view. Exploration of the abdomen was advised, for though he was 75 years old yet as regards powers of resistance he was more than ten years younger. He was himself almost insistent for an operation for, as he said, beyond the colicky pain, he was quite well. Feeling myself that if we are to obtain these cases early enough to be of service we must not wait till all the clinical signs are present I myself urged operation. The wasting might well be attributed to the necessity for careful dieting and this was confirmed by the preservation of all his energy and cheerfulness, by the absence of pallor, and the presence of a strong pulse with good tone. He possessed a good appetite and enjoyed his food when there was no pain. We were fortunate, after he had entered the home, to observe on two occasions an attack of the colic. While taking a meal he had sudden pain, followed by vomiting without nausea. After rejecting a part of the meal already taken he returned and finished the food of which he felt in need. The peculiarity of the attacks confirmed the opinion I had formed myself that there was obstruction at or near the ileo-cæcal orifice.

We decided to perform the operation and after ascertaining the conditions to proceed to excision of the cæcum and as much of the ascending colon as might be necessary. If the glandular involvement proved too extensive for removal, or if he were not standing the operation well, to be content with short-circuiting. Through the right rectus the abdomen was opened, when the moveable swelling was found to be the cæcum. The peritoneum was white and thickened to an unusual degree and the appendix was long and enlarged. The parts looked as if there had been old and frequent peritonitis, without fixation, and that the appendix was the cause of this condition. Further examination revealed a nodular thickening of the cæcum and neighbouring part of the colon. There was no outstanding hard growth, but rather a diffused condition, ending abruptly some one and a half inches above the ileo-cæcal valve. In the mesentery were several enlarged glands. The extreme mobility made the case a suitable one for excision, and as the patient was behaving extremely well under the operation so far we decided to proceed. An examination showed that the liver and parietal peritoneum were free from infection. After ligaturing off the mesentery close to the spine the ascending colon was first divided and the end was closed by two purse-string sutures. Then the ileum was divided and the proximal end was fixed into the side of the ascending colon by a Murphy's button, $\frac{11}{16}$ths of an inch in diameter. The junction was supported by Lembert's sutures, and over and secured to it was laid the end of the great omentum. Though the operation lasted over two hours it was well borne and the patient recovered without any symptoms causing anxiety. The button was removed from the rectum on the fifteenth day and at the end of the third week he was up. The illustration (Fig. 2) shows the form of growth in this case. I have turned the specimen inside out the better to display the distribution of the disease. The growth is extensive, but nowhere deep, is composed of small rounded masses, and involves the ileo-cæcal valve.

This patient soon resumed his active habits, including cycling, notwithstanding a stitch sinus, which caused, however, very slight inconvenience till the end of a year when a piece of silk came away. At the present time (March, 1908) he remains well and shows no signs of recurrence, still cycles, and leads an active life.

The obvious comment upon such a case is the justification of operating at 75 years of age. Everything depends upon the individual. Not only was this man active and vigorous but he had a most cheerful disposition and did not fret under regulations. It is an old truism that the resisting power must not be gauged by age alone. This man had led an monkeys and not men. They added that these were few in number, rarely seen and ate carrion.

Somewhat varying accounts have been given of the stature of the Bushmen, as is shown in the following table:—

TABLE I.—*The Statures of Bushmen as given by Various Authorities.*

Observer.	Male.	Female.
	Mm. ft. ins.	Mm. ft. ins.
Barrow (Cape)	1370 = 4 6	1220 = 4 0
Fritsch (Cape)	1445 = 4 9	—
Topinard (Cape)	1405 = 4 7½	—
Werner (Kalahari)	1550 = 5 1	1500 = 4 11
Schinz	1570 = 5 1¾	—
Haddon	1529 = 5 0¼	—
Pearson (from skeletons)—		
Series 1	1444 = 4 9	1404 = 4 7¼
Series 2	1460 = 4 9½	1420 = 4 8

The skeleton in the Museum of the Royal College of Surgeons of England measures 1332 millimetres (4 feet 4½ inches). Barrow describes one Bushwoman as only measuring 1140 millimetres, and Wisbach a man of only 1000 millimetres; possibly he was not fully grown. The average stature of a series of skeletons obtained from caves on the sea coast which will be subsequently referred to was 1430 millimetres (4 feet 8¼ inches) for males and 1410 millimetres (4 feet 7½ inches) for females.

Before proceeding to a description of the osteological features of the Bushmen it would be well to review briefly the Hottentots with whom they are often confused, although the latter were an invading race at the time of the European occupation of the Cape.

The Hottentots are yellow to olive in colour with tufted hair resembling the former group. They are taller (1600 millimetres, or 5 feet 3 inches), with small but long heads, flat noses, hollow backs, and small hands and feet. They are particularly liable to accumulate fat in the region of the buttocks, a condition known as steatopygia. It is possible they shared this feature with the Bushmen. They were a pastoral people, possessing as domestic animals the ox, sheep, and dog. Their weapons were the assegai, often made only of pointed and hardened wood, knobkerries, bows and arrows, and they used shields of hide. They were grouped in clans with hereditary chieftains of limited authority. They are still to be found in comparatively small numbers in Namaqualand; those still in the Cape under the designations of Karanna and Griqua are half castes. They were not artistic. The distinguishing features from the Bushmen were their stature and their customs. Owing to the confusion which existed in earlier colonial times as to the designation of these peoples descriptions have been very mixed, and investigation into their physical character has been rendered difficult owing to the uncertainty as to whether many specimens sent to English museums really belonged to the race to which they were referred. When the skulls in the collection of this College and in the museum of the Royal Army Medical Corps under the respective headings of Bushmen and Hottentots were contrasted, due allowance being made for the standard deviation of each group, no significant differences could be established. The Hottentot skulls are in most dimensions somewhat larger than those of Bushmen and both absolutely and relatively approach those of the Southern negroes. No materials exist in this country for a detailed comparison of the osteological features other than of the skulls of those two peoples.

Recently attention has been drawn to the remains in the caves, shelters, and kitchen middens along the coast of South Africa from the mouth of the Orange to that of the Kei. These skeletons were found associated with stone implements and sometimes fragments of pottery and are undoubtedly those of the beach-ranging Bushmen, or Strandloopers. These are the section of the race driven as far as possible to the south. They appear to have lived on such food as was driven ashore by the tide and to some extent by hunting. An examination of their skulls and such parts of the skeleton as are available show that they present the characteristics of the Bushmen in an exaggerated degree. A study of the average dimensions of their skulls and their standard deviations shows that while closely resembling and not being clearly distinguished from the up-country Bushmen skulls they could be definitely distinguished from the Hottentots. Their dimensions generally are smaller but the breadth of the head is actually greater than that of the Hottentots, the most striking features being that the Strandloopers are more brachycephalic, orthognathous, and microseme. It seems natural to conclude that these people represent the earlier inhabitants of the Cape and would present the purest racial characters. This view is confirmed by the fact that the coefficient of variation, $\frac{\text{standard deviation} \times 100}{\text{average}}$, is smaller for the group of Strandloopers' skulls than for that of the up-country Bushmen. It may be noted that the small range of variation in the dimensions of the Hottentot skulls shows that these were fairly homogeneous and would not agree with the hypothesis that the latter were a recent racial admixture recruited irregularly from both Bushmen and Bantu.

At the present time the Bushmen have been practically exterminated from Cape Colony, but remain in the Kalahari, possibly extending even a little to the north of the Cunene River. In the past they spread over all South Africa and their weapons have been found as far north as Nyasaland. An occasional individual of the Andorobo tribe has features recalling the Bushman, while the Doko of Larkipia and the Wa-sandawi have been said to be allied to that race, but as yet this is unconfirmed on either physical or linguistic grounds.

A problem of especial interest is that of determining the racial affinities of the Hottentots. As has been already shown, they closely resemble the Bushmen and undoubtedly are allied to that race. Their language, however, presents affinities to those of the Hamitic family which has led to the suggestion that they should be regarded as a cross between some Hamitic invaders of South Equatorial Africa and their Bushman forerunners. Stow and McCall Theal in their histories of the native races of South Africa are emphatically of the opinion that whatever the race mixture which produced the Hottentots was, the Bantu at least were not concerned. Craniological considerations do not, to my mind, confirm this. Unfortunately no good collection of the other bones of this race exist. The appearance of the Hottentot skulls in no way suggests any marked intermediate characters between those of Bushmen and of any more Hamitic race, while in the features in which they differ from the Bush crania they certainly resemble negroes. Prognathism is a marked feature which illustrates this. When the distribution of the various cranial and facial indices is compared it may be seen that the Hottentot in almost every case is intermediate between the Bushmen and the Bantu negroes. A study of the actual dimensions shows a certain similarity between the skulls of this race and those of the Djagga of Kilimanjaro. These differences may be investigated by noting the probability whether or not they could be simply explained by random selection, which can be ascertained from the standard deviations of the two groups. A table has been prepared in which are shown the numbers derived from such a comparison of various groups of skulls. In this table a number above 2 indicates considerable odds against the difference between the respective averages being due to random sampling, while a figure above 3 indicates the practical exclusion of such an explanation. By other methods which will be indicated in the study of the relationships of the negro peoples it can be shown that while the Hottentot measurements are in some respects intermediate between those of Bushmen and of Hamites they are more nearly intermediate between the Bushmen and the Bantu, and where they show this least they resemble the Soudanese negro more than the Hamite. As there is a strong probability that there is a strain of Hamitic blood in the Bantu it seems reasonable that the Hottentots may represent an earlier mixture of that former race with both negro and Bushman, but that they are a true Hamitic-Bush cross without a negro element seems opposed by all the existing anthropometrical evidence. The Hottentots seem never to have been a numerous people and are said to have largely recruited their female element from the Bushmen tribes which they displaced so that the type underwent a progressive change. Against this having occurred to a large extent may be urged the small percentage variability of their skulls and the absence of evidence of such intermixture on a large scale in historic times.

The second group of shorter peoples of Africa are the Negrillos of the central forest zone. In many respects their aged 52 years, was sent to me on Nov. 12th, 1904, by Mr. G. N. P. Carrell of Ilford who had discovered a mass in the patient's right iliac fossa. In August, 1904, he had fleeting abdominal pain, felt as a gripe of short duration, sometimes low down, at others near the umbilicus, though it seemed to start in the right side. There were with these attacks some nausea and loss of appetite. These spasmodic pains lasted four or five days and there was no recurrence till six weeks ago, though some uneasiness remained in the right side. As he put it, "I knew I had a right side." Six weeks previously, on Oct. 1st, these griping pains returned, being again central or right-sided. The spasm lasted about a minute and he now observed some local tenderness. With this recurrence there were no loss of appetite and no nausea. He now for the first time sought medical advice and under Mr. Carrell's treatment the attacks subsided and the sense of "having a right side" disappeared. The swelling about to be described was discovered by Mr. Carrell on making a routine examination.

The patient was a spare, nervous man of the hard-working type and made light of his symptoms. In the right iliac region was a hard, irregular tumour, moving on respiration. The centre of the mass when at rest lay under the rectus. It could be pressed upwards for a short distance and further inwards under the rectus. The outer edge could be slipped away under the fingers. Above the mass there was gurgling on handling, but no peristaltic action could be elicited. The position, the range of movement, the gurgling above, and the size of the mass pointed to a new growth in the cæcum. The range of movement was less free than in a simple and uncomplicated case and suggested infiltration of neighbouring structures, especially of the glands in the ileo-colic angle, and possibly of the omentum. The possibility of the whole mass being due to caseous glands was also in question. Looking, however, to the evidence of the gurgling just above as indicative of the continuity of the ileo-cæcum with the mass, a new growth, involving the ileo-colic junction, seemed the most reasonable conclusion. There could be no doubt that the disease was extensive and that the extension under the rectus indicated considerable glandular enlargement or infiltration of the omentum. The mobility, however, pointed to the possibility of excision and the general condition was fair, though the nervous energy was a little abnormal and deceptive. The patient's condition being, therefore, in a general sense suitable an operation was advised with a view to resection of the cæcum if possible, or if this appeared from the conditions found unwise to attach the ileum to the ascending colon.

On Dec. 3rd, 1904, the abdomen was opened through the sheath of the right rectus, the nerves being easily preserved. The growth in the cæcum was at once obvious, and adherent to the anterior and outer surface below the ileo-colic junction, with its wall infiltrated by growth, was a coil of small intestine. The glands were some of them large but were still encapsuled and had not caused the swelling noticed beneath the rectus. This was due to the adherent small intestine and its mesentery. There were no infiltration of the iliac fossa and no secondary deposit in the liver or peritoneum. Though a double resection was required there appeared no reason, so far as the man's strength was concerned, why it should not be accomplished. The small intestine was clamped with Doyen's broad ligament forceps and three inches were removed. The ends were united by two continuous sutures of silk without the use of any temporary support. The cæcum was isolated by ligaturing the mesentery as near the spine as possible. Glands were found close to the spinal column and there can be little doubt that some were left. The ileum was clamped and divided, then the ascending colon was divided two inches above the growth, and the whole was removed. The ascending colon was closed by a continuous suture through all the coats, drawn tightly, and by another continuous Lembert's suture, thus making a blind end. The end of the ileum was then attached to the lateral aspect of the colon about one and a half inches above the termination by means of a Murphy's button. The junction was further secured by interrupted silk sutures and by folding round the site the end of the great omentum. The abdomen was closed by catgut in this case, one row in the peritoneum and posterior rectus sheath, the other in the anterior sheath. The skin was united by salmon gut. The specimen showed the disease to have commenced in the lower part of the cæcum. To the anterior wall the small intestine was adherent. The ileo-cæcal orifice was obstructed by folding and pressure, not by direct infiltration.

The operation was well borne and by the aid of subcutaneous infusions the patient recovered satisfactorily. The early vomiting was succeeded by the most violent and persistent hiccough I have ever seen. It went on for four days and was not relieved by any of the means employed, even induced vomiting being tried. It was so violent that it shook the man and his bed and was practically incessant. Happily the pulse kept good and counted usually 96, 100, or 110. The temperature never rose above normal. When the hiccoughing ceased we observed some bulging of the wound and later a serous exudation. It was obvious that the abdominal wall had given way and the intestine had escaped. Without anæsthesia the wound was opened up and a large coil of small intestine was found covered by lymph but not strangulated. It was cleaned lightly with saline solution and returned. Then the abdominal wall was closed by two deep rows of silk and a final skin suture. The man, being very sensible and possessed of great fortitude and endurance, bore the operation well, fully recognising the importance of avoiding any recurrence of hiccough which anæsthesia might induce.

The patient recovered without giving us any anxiety and was soon taking his food well. The abdominal wound was, however, never comfortable, and, as might well be expected in such circumstances, the silk sutures began to give rise to trouble, and for this one was prepared. However, the appearance of the skin, though united throughout, was unusual. It was raised in dark bluish-red elevations and the swelling did not subside with the escape of pus, as is usual with suture suppuration, and one feared that the abdominal wall had become infected with growth. Six weeks from the first operation he went home with the wound still swollen. Some weeks later the sinuses were curetted and it became clear that a soft growth infiltrated the abdominal wall. Gradually this spread up and down the rectus, forming bluish-red elevations and preventing his holding himself erect. Later a fæcal fistula formed and he died from exhaustion.

The infection of the abdominal wall in this way I have not seen before or since. It is common to open the peritoneum and give exit to serum in malignant cases, and even to divide peritoneal nodules, without infection of the wound taking place, so that infection by cancer cells during the operation is unlikely, because it ought to have occurred in other and similar cases. That all the growth was removed there is, I think, no doubt, for everywhere it was free and unbroken. It is possible, however, that in dealing with the glands close to the spinal column cancer cells may have been liberated and one may even have cut across a gland and so infected the peritoneum. But, again, this has been done before without such a result as happened in this case. Whatever view we take—i.e., whether the peritoneum was infected before or during operation—the fact determining the wound infection was the protrusion of the bowel and its presence there probably for two or three days. We had no necropsy, but it is not difficult to imagine that the colon became adherent to the abdominal wall and perforated.

Was it wise, in the presence of adhesion and infiltration of a coil of small intestine, to proceed to extirpation? Does such an infiltration indicate peritoneal infection? The answer to these questions surely is, that we had to deal here, so far as we could judge, with a local adhesion and infiltration, and that in the ascertained absence of nodules in the parietal and visceral peritoneum and in the liver the proceeding as carried out was justifiable. Had the hiccough not determined yielding of the catgut and protrusion of the intestine, there can be little doubt that primary union would have occurred and a considerable interval of good health would have been enjoyed. That recurrence would ultimately have ensued there can be no doubt. The imperfect removal of glands seemed at the time the only unsatisfactory part of this operation, yet in other instances where apparently removal was imperfect immunity has been maintained for some years as in Case 3.

Diagnosis.

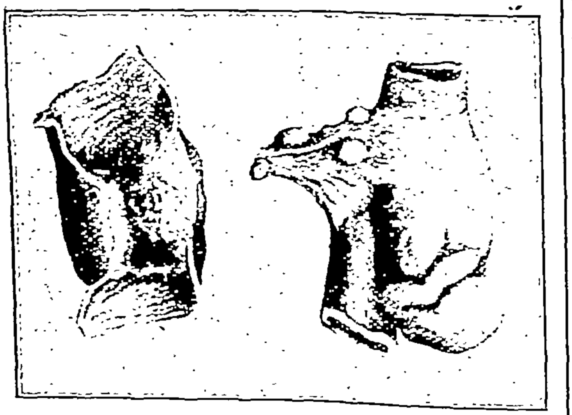
As I have said earlier in this lecture I doubt if any other condition gives exactly the form of tumour described as typical of malignant disease. The swellings in the region of the cæcum, raising the question of diagnosis, may be classified thus:—

First, because most common, come the conditions resulting from appendicitis. The induration disappears in this condition, except when the concretion escapes and lies in a cavity outside the appendix. It is then that lime salts to the transverse colon the functions are practically undisturbed.

The purpose of this lecture will be to point out the characters of early cancer of the cæcum, and if time permit of the ascending colon, to show the comparative safety of operation in suitable cases, and the degree of immunity from recurrence that may be secured. The two main signs of malignant disease of the cæcum are the presence of a tumour and the occurrence of early intestinal colic due to obstruction of the ileo-cæcal orifice. The tumour in its most typical form is in my experience unlike any other morbid condition about the cæcum. It presents as a moveable, hard, well-defined tumour, so close to the abdominal wall that it may be grasped by the hand and even lifted from the posterior wall. From a position of rest the mass can be moved downwards for some distance, swinging as it descends towards the median line and the margin of the rectus; upwards it may be moved as far as the ribs, or half the distance, making a vertical course and not passing into the loin. During this movement a gurgle is often felt from air passing through the stricture. The range of movement will vary with the mobility of the cæcum in each individual. This part of the bowel may, for instance, be more or less tethered by a past appendicitis, and in women is more moveable than in men. The discovery of a tumour by the patient may be the first evidence of disease, as in Case 3. Intestinal colic, at first occasional and brief, may exist for some time before the patient comes for advice, and even then it is often treated without the possibility of a growth being kept in mind. In its more developed stages this colic is sharp, short, attended with gurgling and pain in the right iliac region. If the patient be taking food at the time of the colic part of the food may be rejected without nausea and he may return to his meal. This feature will be seen in one instance to have been of great assistance in forming the diagnosis. Colic will be an early symptom if the growth begins in the lips of the ileo-cæcal orifice. On the other hand, it may be absent in disease beginning in the posterior wall or just above the orifice. All these points are well illustrated by the following case:—

CASE 1. *Cancer of the ileo-cæcal valve; resection; well ten years later.*—The patient, a married woman, aged 48 years, was sent to me on Dec. 13th, 1897, by the late Mr. G. H. De'Ath of Buckingham. In July, 1897, she had great pain in the "centre of the stomach" and round the body with sickness. There were three such attacks in 14 days. In August there was a return of sharp spasmodic pains all over the abdomen. In September Mr. De'Ath examined the abdomen without finding any "internal enlargement." At this time, owing to her husband's illness, the patient was unable to attend to her own ailments, though the pains continued. From Nov. 5th to Dec. 5th the pain was worse and became right-sided, and at times she could not stand. For the last year she had not been well and had lost flesh. When seen by me on Dec. 13th the patient showed no evidence of a general illness. The pain was of a definite colicky type, was felt all over the abdomen, but most severely in the right iliac fossa. There was also gurgling with the pain. At the height of the spasm of pain she was frequently sick. In the right iliac fossa a hard irregular lump could be felt. It was moveable upwards and to a less extent downwards, swinging in its descent towards the median line. It could also be moved towards the umbilicus. It was easily handled and could almost be grasped. When the intestine had been irritated by friction, coils were visible and gurgling could be heard. The diagnosis gave in this case no great difficulty, for in addition to a mass possessing the characters of a new growth of the cæcum there were also visible coiling, gurgling, and the colicky pains characteristic of obstruction. The early onset of pain and the evidence of obstruction indicated that the ileo-cæcal valve had been primarily involved. The cæcum was removed in December, 1897, together with a large piece of mesentery containing enlarged glands. The end of the colon was closed and the ileum, considerably thickened, was united to the lateral aspect by a Murphy's button. The patient recovered rapidly from the operation and was alive and well in 1908—more than ten years after the operation.

FIG. 1.



Cancer of ileo-cæcal valve. The right-hand figure shows the growth involving the cæcum and appendix and the lymphatic glands. The hypertrophied ileum is seen in the lower half of the figure. The left-hand figure shows the growth in section.

The illustration (Fig. 1) shows the lips of the valve to be primarily involved, while the wall of the bowel is also infiltrated through to the peritoneum. Several enlarged glands are also visible. The hypertrophy of the ileum will be noticed. It was fortunate for this patient that the disease involved and obstructed the ileo-cæcal orifice, as the pain demanded relief.

The disastrous result of delay is shown by the following case seen in consultation with Mr. R. R. W. Oram of Wandsworth.

CASE 2. *Cancer of cæcum; extensive operation; death from hæmatemesis.*—The patient, a married woman, aged 34 years, was seen on June 8th, 1900, at the request of Mr. Oram. She gave a history of an attack of abdominal pain 14 days before. The whole "stomach" was sore and she had to remove her corsets. The pain soon ceased and she had a good night. On the next morning she had a temperature of 100° F., and a lump was found in the right iliac fossa. As this did not disappear with aperients, and was recognised as differing from the usual appendicular swelling, I was asked to see her on the above date. In the right iliac fossa, just above the line from the anterior spine to the umbilicus, was a hard, abruptly defined, freely moveable mass. Upwards it could be moved nearly to the ribs, downwards and inwards to the rectus margin, and also directly inwards. Examination gave no pain in the mass itself nor was there any dragging sensation felt in the pelvis. The mass could, like some of the others referred to, be grasped by the hand and raised from the iliac fossa. The situation, the special range of mobility, the history of pain of a colicky character, all indicated the presence of a growth in the cæcum. This opinion was given and the wisdom of immediate operation was pointed out. The age might seem to be a point against the diagnosis, but here previous experience showed that malignant growth at the age of 34 years is not uncommon in the large and even in the small bowel. I may mention a man with cancer of the cæcum at 34 years of age, and I have operated for malignant stricture of the hepatic flexure at 28, of the sigmoid at 19, and I have seen typical colloid cancer of the rectum at 16. That the lump in this case might be inflammatory and due to appendicitis was suggested by the sudden attack of pain 14 days before, by the rise in temperature, and by the finding of a lump on the next day by Mr. Oram. I would venture to lay down the fact that such mobility as was observed here never occurs with inflammatory swellings due to appendicitis. I have seen a swelling due to a large crystalline formation round a pin remain for three months unaltered, but it was an immoveable swelling. A fæcal accumulation again does not, so far as I have seen, present so hard and limited a tumour, nor is it so moveable. It might have been a moveable kidney containing a stone, but against such a view was its rarity and the crucial fact that when pressed up the tumour dragged from below, evidently from an attachment in the iliac fossa, and again did not disappear into the loin. The shape and size excluded an ovarian with a long pedicle.

Before deciding upon operation the opinion of a physician was sought in July and he, to my regret, counselled against operation, so far as I could gather for two reasons: first, because the lump was moveable and looked therefore so growth, and yet, though just upon four years have elapsed, he is well and in full work—a better result up to now than I had anticipated. That many of these glands are free from cancer is no new observation. The subsidence of submaxillary glands, secondary to a foul malignant ulcer of the tongue or pharynx, when the primary disease has been removed or rendered aseptic by the x rays or by vaccine, is well known. Therefore it must be a very extensive infection that should set a limit to excision, and by this time probably there will be stronger local reasons for abandoning the operation. More important is the character of the glands. Those met with have been all smooth and succulent; it is the hard nodular enlargement that shows definite infection. Even, however, when glands must be left removal of the primary disease should not be abandoned when other conditions are favourable, as a considerable measure of relief will follow.

Involvement of a neighbouring coil of intestine is not, as a rule, a bar to excision, for there need be no general peritoneal infection. In the case recorded here (Case 4) there can be little doubt, as the sequel proved, that general infection existed. We have no means of ascertaining such a degree of infection, for there was no serum and therefore, other things being favourable, I see no reason against a double resection.

Should pallor or anæmia deter us from operation? I suppose one may recognise three forms of pallor in malignant disease: that which is due to dissemination of growth, that which is due to small and unnoticed losses of blood, as in gastric carcinoma, and that caused by septic absorption from necrotic changes in the growth. This last form comes early in malignant disease of the bowel, as it does in cancer of the mouth, pharynx, and œsophagus. It is the form relieved by injections and the x rays. Certainly pallor in patients over 60 years of age, and in younger people whose visceral conditions are not sound, sets a limit to extensive operation. Occasionally, however, when the patient is young and robust it may be safe to operate in the presence of this condition. The following is a case in point. In a man aged about 40 years, of a particularly robust constitution, with a large malignant growth of the hepatic flexure, and, except for his pallor, in good general condition, I resected the cæcum and colon to the middle of the transverse portion successfully. The removal of the mesentery involved opening the lesser sac and a dissection over the duodenum to the pancreas, and yet he is at the present time, just four years from the operation, in full work. The limits as to age I have already referred to and as to cardiac conditions of a nervous kind.

The established rule to postpone resection followed by anastomosis and to be content with anastomosis only when the contents of the bowel are septic is applicable here as elsewhere. When this exists the ileum should be united with the colon by direct suture and ten days later the resection carried out. It is better to make the first operation through the median line, leaving the rectus sheath for the resection. The presence of visible peristalsis is not in itself a bar to immediate resection, for the small intestine may be capable of emptying itself and the contents may not be septic. But when, with peristalsis, the small intestine continues to be dilated then, resection carries special dangers and should be delayed till the bowel is healthy. Some years ago, before one was perfectly clear on this point, I lost two patients from attempting the full operation in the presence of obstruction.

Palliative Treatment.

Short-circuiting will relieve where the disease is too extensive for removal. The question arises here whether lateral anastomosis of the ileum to the transverse colon is sufficient without division or some other method of occlusion of the ileum beyond the junction. No doubt it is more perfect to prevent the contents of the small intestine passing over the growth, but I doubt if it does any great harm in an inoperable case. I have carried out anastomosis by direct suture of the ileum and transverse colon on several occasions without being able to detect any special disadvantage. On the other hand, there is a tendency for the fæcal material to accumulate between the junction and the obstruction if the ileum be divided or otherwise closed, giving rise to much inconvenience. The passage of even a small amount of the bowel contents through the stricture appears to be sufficient to prevent this accumulation.

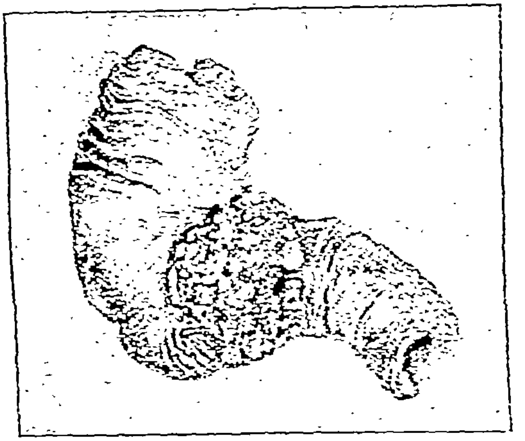
The Value of the Murphy Button.

It will be noticed that the junction of the ileum to the colon was effected in the cases here reported by the excellent mechanical device introduced by Mr. Murphy. For making a junction between the end of the small intestine and the side of the large in the absence of septic contents I find this method more convenient than direct suture. Here I must, however, insist that I never use the button without supplementing it by a row of Lembert's sutures all round, and where possible enfolding the junction by the great omentum. The size of the button must be under an inch—the $\frac{11}{16}$ths I find a convenient size—or even a smaller one makes a sufficiently large opening. It is also of importance to see that the spring is strong enough, for buttons are sold imperfect in this respect. Again, in joining the end of one piece to the side of the other it is most important to be sure of the vascularity of the ileum. The first section may appear flabby owing to the ligature of the mesenteric vessels: if so, a further piece must be removed. The cut surface, in fact, should bleed freely. I am inclined to think that some of the failures reported with Murphy's button have been due to neglect of these points. The line of division of the bowel has not been made to secure vascularity of the part opposite the mesentery, or the button has been too large, or again pieces of septic mucous membrane have been left protruding, or there has been too much strain on the junction, and lastly, the protecting Lembert's sutures have not been inserted. It will also be observed that end-to-end junction of the small to the large intestine was not employed, but instead anastomosis of the end of the ileum into the side of the colon, the lumen of the latter having been previously closed by two continuous sutures. It is difficult to suture the ends of the small and large intestine and it is unnecessary and, moreover, it takes much longer. The third plan is to close the ends of both and make a lateral anastomosis. It is the best if direct suture be employed, for it is easier, safer, and quicker—even including the time necessary for closing the ileum—than joining the end of the ileum to the side of the colon. The button I find then of great service whenever the bowel is healthy and the contents are free from the septic changes of obstruction. For end-to-side anastomosis it is admirable, especially when the upper and lower pieces of the bowel differ in size; for example, in chronic obstruction of the ileum from tuberculous or malignant stricture the lower end is thus inserted into the side of the upper, a thin and normal piece into a greatly dilated and thickened piece.

I must not conclude these lectures without some reference, however brief, to the physician in whose memory they have been founded. A perusal of Mr. Pettigrew's "Memoirs" and some of the many letters he has collected leaves the impression that Dr. Lettsom was a man of remarkable character. To yield up your only source of income at 23 in order to free your slaves requires some courage. With the money saved out of his first six months' practice he returned to England and completed his education, both here and on the continent, and at 26 began practice in London, as it is quaintly put, "under the protection of Dr. Fothergill," which means, I suppose, that he joined him in partnership. He was only 29 when he was chiefly instrumental in founding the Medical Society. Whatever movement was on foot for the promotion of scientific investigation or for the benefit of the poor Dr. Lettsom took an active part. He founded the Royal Humane Society and the Sea Bathing Infirmary at Margate and was president of the Philosophical Society at the time of his death. Writing when 46 to a friend older than himself he says, "I grow old rapidly. The sempster time has lately worked up my thread very fast and I want a pause between the two worlds." His activity, however, did not diminish and when Jenner published his discovery in 1797 Lettsom, then 53, actively took up the new treatment, and so valuable was the paper he wrote in its support that it was republished at Jenner's request. It was to his friend, Dr. Waterhouse of Cambridge, Massachusetts, that the first consignment of lymph was sent to America. His end was typical of his active life. He had made a necropsy and probably was infected. Rigors soon followed but he insisted on going about, resisting the advice of his friend Pettigrew that he should see Dr. Babbington. He, however, was obliged to submit and a week after the onset of the illness he died at the age of 71, in the year of Waterloo. The many letters received showed in what esteem he was held alike by his own profession, by scientific men generally, and by peers, eminent lawyers, and others.

Many valuable lectures have been given under this memorial to Dr. Lettsom. I cannot but [illegible] that abstemious, healthy, outdoor life and his mental powers were in keeping with his bodily activity. He was, moreover, of a cheerful disposition, and himself long accustomed to high naval command, took everything as a matter of course. In estimating resisting power in malignant disease nothing, I take it, is more important than to distinguish between the wasting due to cachexia and that due, on the one hand, to interference with digestion only, or on the other, to pain or other symptoms that may induce loss of sleep. The patient who preserves his energy and vigour, his mental alertness, and has a pulse of good tone may be estimated as possessing good resisting power. One must not be deceived by the man who exhibits a fictitious activity, beneath which one can recognise artificial stimulation and the signs of arterial and visceral degeneration. This and Case 1 indicate what might have been done in Case 2 if operated upon when advised. Age, then, is in itself no deterring condition, nor are certain conditions of the heart and general health, as shown by the next case.

FIG. 2.

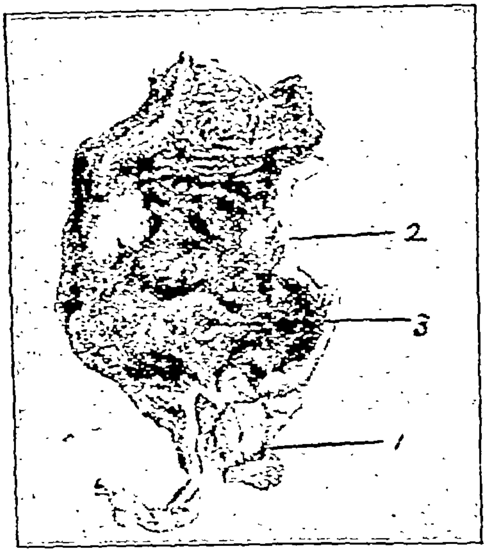


The cæcum and ileum have been turned inside out to show the flat nodular ulcerating growth. The patient was 75 years of age.

CASE 4. *Cancer without obstruction of the valve; resection; recovery.*—The patient, a married woman, aged 59 years, was brought to see me by Dr. G. C. Steele-Perkins on Feb. 29th, 1904, with the following history. Five weeks before, while rubbing the abdomen, she had noticed a lump in the right side, and for this consulted Dr. Steele-Perkins. On Feb. 10th he found a hard moveable swelling in the situation of the head of the cæcum. There were no tenderness on handling and practically no associated symptoms. Looking upon the swelling as in all probability partly fæcal, aperients were administered and some reduction in size was effected, but as the main tumour still remained I was asked to see the case in consultation. The mass lay in the right iliac fossa, was hard, somewhat nodular, and freely moveable. Its position of rest was in a line drawn from the iliac spine to the umbilicus; it could be moved upwards nearly to the ribs and downwards to the outer border of the rectus. It could be almost surrounded by the hand and grasped. It resembled in some respects a moveable kidney and could indeed hardly be confused with anything else. The position of rest was, however, quite against this view, for, so far as I have seen, neither a loose kidney, a moveable right hepatic lobe, nor a gall-bladder ever occupies so low a position. Again, none of these structures give the nodular outline found in this mass. There was no gurgle in the lower part of the ileum nor had there been any colicky pains. The valve was, therefore, at present free. The mass was higher than the usual situation of the ileo-colic valve and we considered the infiltration as beginning in the posterior wall above this orifice. This situation would explain the absence of obstruction. The patient herself was a highly nervous woman and suffered from "heart disease." We ascertained that she had consulted Mr. F. G. Larkin of Grove Park for the cardiac condition. On communicating with him we found that a marked irregularity with attacks of dyspnœa from time to time were the chief signs of the cardiac ailment. Mr. Larkin had considered the condition mainly a nervous one and had never found evidence of organic disease. Still, the fact remained that the woman was by no means a favourable subject for operation. The growth, however, was, so far as we could ascertain, still limited to the cæcum. As to the duration it appeared that six months before a small nodule had been observed in the situation of the present mass by Mr. Larkin, of which, however, no further notice was taken. On March 14th the patient was moved into a nursing home, but this brought on so severe a nervous attack that she had to return to her own home next day. In a few days, however, she was able to face the operation which was performed and in the able hands of Dr. J. F. W. Silk the patient took the A.C.E. mixture without causing the slightest anxiety.

The growth, as shown in Fig. 3, involved the colon just above the valve and though the orifice was displaced it was not obstructed. The glands in the mesentery were numerous, though for the most part accessible. The cæcum and nearly the whole length of the ascending colon were removed, together with the mesentery and glands up to the spinal column. The distal end of the colon was closed and the end of the ileum united by means of a Murphy's button to the inner aspect, two inches beyond the closed extremity. Once the operation was over the patient's nervous symptoms settled down and an excellent recovery followed. The glandular enlargement was in this instance beyond complete removal. The furthest gland removed was of fair size and there can be no doubt that smaller and more distant ones existed. It was the interference with vessels in removing the glands that necessitated so extensive a sacrifice of intestine. The case demonstrates the comparatively small risk of such an operation, even in unfavourable subjects. Obtained early the prospects of complete immunity are most encouraging. This patient died rather more than three years after the operation from some cardio-pulmonary condition that was not attributed to recurrent disease.

FIG. 3.



The ileum is seen below (1). The growth (2) is seen just above the ileo-cæcal valve (3).

A tumour that may appear before the abdomen is opened a possible case for excision may prove inoperable or nearly so when brought into view. Dismissing the questions of secondary infection of the peritoneum and of the liver as obvious contra-indications, does infiltration of a coil of adherent intestine negative resection? The following case shows that this can be successfully carried out, but also indicates that there was peritoneal infection, though not yet advanced to the stage of deposit. As the case illustrates several important features of disease of the cæcum and some of the troubles following upon these extensive operations it is worth recording in detail.

CASE 5. *Cancer of cæcum and of an adherent coil of ileum; double resection; hiccough: protrusion of bowel; malignant infection of the abdominal wall.*—The patient, a man, applied extensively in therapeutics. The change is a gradual one and occurs in most cases only if carbohydrates greatly exceed the needs of the tissues. There is no conclusive evidence that in health this change occurs if carbohydrates are not in excess. In disease, however—e.g., diabetes—it is possible that sugar may be burnt off by becoming first converted into fat[3] by a conjoint process of reduction and synthesis akin to that which occurs in butyric acid fermentation. The site of this change is most probably the liver, since similar processes have been proved to occur in the liver after death.

Disturbances of glycogenesis, whether arising from defective storage or increased glycolytic changes, are therefore always attended by disturbances in fat metabolism, in the first instance by diminished formation of fat and later by increased call upon the fat already present in the body to take the place—for purposes of combustion and nutrition—of the carbohydrate material lost to the body. More or less wasting is thus a characteristic effect of all disturbances of glycogenesis. In the case of fats, the deficiency or loss of carbohydrates leads to the removal of fat from its deposits in the tissues back into the blood to all the organs requiring it but especially into the liver. The liver becomes loaded with enormous quantities of fat to the extent, it may be, of 70 per cent. of its bulk. This transference of fat involves therefore a condition of lipæmia met with in cases of diabetes which may in itself be sometimes a cause of disturbance in producing fat-embolism. It involves, however, what is more important—viz., an excessive metabolism of fats for purposes of combustion, and with this a corresponding excess of products of fat metabolism. Among such products are various acids, diacetic acid, acetone, β-oxybutyric acid—the so-called acetone bodies. The greater part of these bodies have fatty acids as their immediate precursors, and the liver is the site of their formation from fat (and from proteid derivatives). The essential factor in causing acetonuria is the absence of proper carbohydrate metabolism. The effects on liver function of the "acidosis" thus produced are various. Some of them have already been seen in connexion with its metabolism of urea and ammonia. The most dangerous result is that shown in diabetic coma, the grave toxic symptoms of which are associated with the presence of these bodies. The body is able to protect itself up to a certain point against this increased production of acids—viz., by neutralising them with ammonia. This combines with the acids and is excreted in the urine to the amount even of from 10 to 12 grammes daily, instead of the average 0·5 gramme. Notwithstanding the protective power of the ammonia the alkalinity of the blood may become absolutely diminished, and then there follow the phenomena of acid-intoxication presented in cases of diabetic coma. Short of these extreme effects, the diminished alkalinity of the blood caused by increased formation of acids may in certain cases, as will presently be seen, involve grave disturbance of the proteolytic functions of the liver, to the extent even of becoming the main factor in determining the occurrence of the gravest of all liver disturbances—viz., the auto-digestion (autolysis) characteristic of acute yellow atrophy and of some cases of chloroform poisoning.

Both directly and indirectly defective glycogenesis may thus be responsible for some of the gravest disturbances, both functional and structural, to which the liver is subject.

1. Absence or deficiency of carbohydrate material (glycogen) in the liver cell involves on the one hand an increased destruction of protein material with consequent wasting of the body.

2. This increased proteolysis involves an increased formation of toxic products in increased quantity, with consequent increased liability to toxic effects producible by such products.

3. The absence of glycogen from the liver cell by diminishing the combustion processes interferes with the destruction of toxic products, and this involves a diminution in the antitoxic powers of the liver cell. The starving animal is more easily affected by poisons than the well-fed (glycogen rich) animal.

4. The loss of carbohydrate material caused by impaired glycogenesis (and the glycosuria of disease) involves extensive changes in fat metabolism—the withdrawal of fat from its peripheral depôts to the more centrally situated liver, where it is more immediately available for purposes of combustion and energy production. The increased metabolism of fats thereby necessitated involves an increased formation of acids and if long continued the "acidosis" thus occasioned may produce symptoms of acid intoxication of milder or severer degree (e.g., acetonuria and diabetic coma). It may even in favourable circumstances be the chief factor determining the onset of the severe structural autolytic changes characterising acute yellow atrophy, chloroform poisoning, and other severe liver conditions.

DISTURBANCES CONNECTED WITH THE METABOLISM OF FATS.

Disturbances in fat metabolism play a far more important part in grave functional disorders of the liver than was formerly supposed.

A. *The physiology of fat metabolism.*—The neutral fats absorbed with the chyle remain in the blood for a brief period till they are selected for combustion or storage in the subcutaneous tissues, para-peritoneal spaces, and the liver. During fasting the fat streams from the depôts back into the blood to all the organs requiring it. A condition of "lipæmia" of the blood is therefore a constant condition and this becomes very manifest in phosphorus and phloridzin poisoning, in alcoholic intoxication, and in diabetic coma—conditions in which there is more or less widespread inanition, especially with deficiency of carbohydrates. Certain ferments have been found in the blood capable of splitting the fat and rendering it soluble. And ferments of this nature have been found in the liver. In these conditions, as has been shown by Rosenfeld (1895-97), an enormous passage of fat takes place from the fat deposits of skin and abdomen into the liver, and the latter becomes loaded with enormous quantities of fat (to the extent of 70 per cent. of its bulk). The distinctions formerly made between "fatty infiltration" and "fatty degeneration" no longer hold good. In both cases alike the fat is deposited in the cells; the form it takes—whether in fine granules or larger globules—is determined by the functional activity of the cell at the time the fat is taken up. This excessive storage of fat in the liver only occurs if the glycogen has disappeared from the liver, and it can be prevented if the animal be fed with substances, such as sugar, from which glycogen can be readily formed. This storage of glycogen and fat would thus appear to stand in a certain antithesis. Although in certain cases large quantities of fat may often be found along with extensive storage of glycogen—e.g., in the livers of Strassburg geese (Magnus Levy)—yet in general excess of fat in the liver denotes deficient glycogenesis. The storage of fat in the liver may be explained in two ways. The first is that the liver must first transform the fat molecule in some way before it can be consumed by the cells (Nasse)—for example, possibly into carbohydrates. The second is that the storage of fat in the liver is a reserve readily available to meet any sudden call upon the metabolism, as, for example, in violent movements. The suggestion is that the fat can much more quickly and easily pass from the centrally situated internal and vascular liver than from the cells of ordinary adipose tissue. According to this explanation, the liver must have the task of placing at the disposal of the body the material necessary for combustion, both from its glycogen and its fat deposits, on any sudden increase of the demand for energy. (Von Noorden.)

B. *The pathology of fat metabolism.*—The disturbances that arise in connexion with fat metabolism in the liver are evidenced chiefly by the excretion of acetone bodies—viz., acetone, aceto-acetic acid, and β-oxybutyric acid, and by the condition of acidosis to which their formation in excess gives rise. Of these bodies only acetone can be found in the urine in health (about one to three centigrammes daily). The conditions under which these bodies are increased are essentially those in which the oxidising powers of the body are reduced by some notable deficiency or absence of carbohydrates from the food. Deprivation of food or the exclusion of carbohydrates from the food causes acetonuria without exception in the case of man, also in children, also during pregnancy and labour, also after injury of the central nervous system, also after the administration of narcotics. In all these cases the administration of carbohydrates, starch and especially sugar, removes within a few days this form of acetonuria. If it be allowed to continue there also occurs an excretion of aceto-acetic acid and oxybutyric acid. The source of these become deposited over a fæcal concretion or over a foreign body. I have a specimen where a pin has been covered by a large crystalline mass. The man was 30 years old and the lump existed for over three months, and may have been there before. Altogether I have had seven such cases. In all these the patients had had acute attacks, the mass was hard and fixed, did not increase in size, and did not give rise to colic. In a man over 60 years of age there was a hard irregular lump fixed to the abdominal wall. It could be outlined quite easily, but it was too small for an adherent growth and did not reach deep enough into the iliac fossa. It proved to be the appendix in the very unusual position of being adherent to the abdominal wall and surrounded by the effects of a recent acute attack. Fixation and a small mass were the two great points in diagnosis. The resemblance was exemplified in Case 2 where after an attack of pain in the night a lump was found and the temperature was raised. The persistence and mobility of this mass led, however, to further advice being taken. The danger of a brief and single examination was well seen in the case of a man of 42 years brought to me in November, 1899, for removal of the appendix. A history of several attacks of pain was given; he had been seen in February by an eminent authority in one of these attacks, with slight elevation of temperature, when operation was advised. In May there was another attack of pain which laid him up for a week, and all the year there was indigestion. The night before I saw the patient he had been in a good deal of distress. All arrangements had been made for operation, the day settled, and the forthcoming marriage was to follow. Wishing to see the patient before deciding upon the operation he walked in apparently with ease and alacrity, rather thin and pale, but considering himself well except for this pain. He had been shooting and otherwise going about as usual. The presence of extensive growth was only too obvious, not only in the cæcum and iliac fossa but in the pelvis and in the omentum. The surprise at such a diagnosis was naturally great and exploratory operation was insisted upon. This took but a few minutes, the parts needing little disturbance to confirm the widespread character of the cancer. The end was tragic, though merciful. Propped up in bed smoking a cigarette on the fourth or fifth day he fell back in a moment dead from cardiac embolism.

---

[3] Von Noorden, 1901; Naunyn, 1899.

Secondly, when cancer attacks the posterior wall early perforation may take place with fixation and suppuration. Here the resemblance to subacute cases of appendicitis—cases commencing even about 60—is very close. I was called some years ago to relieve a patient with flexion of the hip after suppuration in the iliac fossa. The abscess had closed and the case was looked upon as one of appendicitis. I found the iliac fossa occupied by a hard growth, a mass in the cæcum, and typical peristalsis of the ileum. The cæcum, which I obtained later, showed an epitheliomatous ulcer on the posterior wall less than an inch in diameter. The iliacus muscle was infiltrated with cylindrical epithelioma. I refer to this type of case because, though representing a later stage of disease, we may be called upon to give an opinion when fixation has occurred and even suppuration. I have notes of another case where the patient came with a sinus over the iliac crest exactly resembling that occurring after suppurating appendicitis. The close resemblance must some time find the surgeon operating upon what looks like a non-malignant condition.

The next mass found in this region is caused by glands in the angle between the ileum and cæcum. In four cases these formed definite tumours. In a girl of 20 years it was very hard and irregular and though lying further inward than usual it was, I thought, due to an escaped concretion round which lime salts had been deposited. A mass of calcareous gland was found in the ileo-colic angle and removed. The appendix was free and was also removed though it showed no tuberculous deposit nor was any observed in the cæcum. This patient later had signs of general tubercle. Another case occurred in a young man of 19 years. Here the glands were succulent and infiltrated the walls of both portions of intestine; they were not removed for resection of the cæcum would have been required. The patient has completely recovered. Glands in this situation occur mostly in young people when the diagnosis of malignant disease may be put aside. But occasionally an old centre may recrudesce and give rise to much difficulty. In a man over 40 years seen in consultation, where the question of malignancy was raised, such a condition had probably existed in earlier life. The thickening was irregular, without the characteristic movement, and not so abrupt and defined as has been described. Subsequent progress justified the withholding of an exploration in this case.

A gland situated on the inner aspect of the ascending colon, one and a half inches above the junction of the ileum and already suppurating, gave rise to some difficulty in diagnosis, especially as the lump moved with the cæcum. The patient having a good deal of pain and being about 30 years old, operation was considered wise. The abscess, a small one, lying under the peritoneum covering the colon at the mesenteric margin, was dissected out and a good recovery followed.

A fourth condition is tuberculosis of the cæcum. The resemblance between these two conditions was fully illustrated in the paper read by Professor Hartmann before this society on Ileo-cæcal Tuberculosis. It may be said that tuberculosis occurs in earlier life and that fixation arises sooner than in cancer. The resemblance is seen in the situation and form of the tumour, the colic, and the obstruction at the ileo-cæcal valve. Again in both suppuration may occur and a fæcal fistula ensue. In a woman, aged 24 years, under my care in Guy's Hospital in 1895 with a fæcal fistula and a hard irregular mass in the cæcum there was a history of obstruction and pain. In two stages the cæcum was excised and the ileum joined up with the colon. The disease was tuberculous and this view was further supported by her admission last year with spinal disease and old phthisis. Professor Hartmann's paper showed that even when exposed such a mass may be difficult to distinguish from cancer. Both require removal so that error is of less moment except so far as regards the extirpation of lymphatic infection.

Actinomycosis in its early stages resembles more closely that form of appendicular swelling due to a calcareous-covered concretion in that both tumours are fixed and do not disappear. In the later stages, when infiltration and suppuration occur, there is a resemblance to that form of malignant disease beginning in the posterior wall and attended by suppuration. Both conditions are at this period, however, inoperable. A typical case will be found recorded in the Transactions of the Royal Medical and Chirurgical Society, vol. lxxv., p. 63, by the late Dr. Ransome, with whom I saw the patient on several occasions. This patient in 1886 had some uneasiness in the right iliac region and thought he had a hernia. On Oct. 12th, 1888, he had indefinite and occasional pains, pain at sometimes severe and at irregular intervals and increased by movement of the right leg. On the 21st he was seized with great pain in the right iliac fossa. Then was there found a distinct, firm, rather uneven, solid mass, very tender to pressure and in the position of the cæcum. From this time there was rapid extension to the iliac fossa and abdominal wall and he died with secondary deposits in the liver and brain.

Limits of Operation.

So mobile is the growth, even in some advanced cases, that until the abdomen is opened one cannot be certain whether extirpation is possible or not. Even then it is sometimes difficult to decide and one is tempted to go forward when the glandular infection cannot be fully limited. The presence of ascites and of secondary deposits in the peritoneum or liver puts excision out of the question. Adhesion to the posterior wall with infiltration of the muscle or with a sinus also makes removal impossible. Infiltration of the anterior abdominal wall, unless very limited, must also render complete eradication impossible. In one instance I undertook the removal of recurrent growth where the scar in the abdominal wall was involved. Some time before another surgeon had opened the cæcum and removed a polypus attached to the posterior wall. Though I made a wide removal of the intestine and abdominal wall recurrence took place rather quickly.

How far should enlarged glands set a limit to the question of resection? Theoretically a gland as large as a bean, close to the spine, infers lymphatic infection beyond and points to the impossibility of eradicating the disease. On such a view resection ought to be abandoned. Experience, however, renders a different answer, for in the patient, aged 75 years, a gland was inclosed in a ligature, and part had to be left, for already the dissection had reached the aorta, yet he shows no signs of recurrence after four years. In a case not recorded in this lecture, where the whole of the ascending colon together with the hepatic flexure and the cæcum were removed, it was quite impossible to get beyond all obvious gland enlargement, though at the attempt the duodenum was uncovered and the lesser sac of the peritoneum opened up. This man showed also the pallor caused by necrotic

those you have been good enough to listen to have fallen short of any great attainment. Still, perhaps the cases recorded may prove of some value to future workers and enable them to generalise to better purpose.

DELAYED CHLOROFORM POISONING: ITS NATURE AND PREVENTION.

BY WILLIAM HUNTER, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE LONDON FEVER HOSPITAL.

IN view of the importance of the condition itself and of the additional interest given to it by recent communications in THE LANCET, the conclusions come to by the present writer in dealing with the subject in the forthcoming edition of Allbutt's and Rolleston's "System of Medicine" may fittingly be drawn attention to at this time.

The credit of being the first to draw attention to cases of "delayed chloroform poisoning" belongs to Dr. Leonard G. Guthrie. In 1894 he reported nine cases in which death occurred within from ten hours to six days of operation performed under chloroform. The exact numbers of hours which elapsed between the operations and the deaths of the patients were 10, 12, 13, 16, 24, 27, 30, 53, and 150 respectively. In Case 10 recovery took place after symptoms of great gravity had lasted for nearly three days. The symptoms and clinical course noted in such cases were—after a period of 12 hours or so—profuse and repeated vomiting; the vomit eventually blood-stained and resembling the dregs of beef-tea, restlessness, excitement, delirium alternating with periods of apathy, jaundice occasionally, and unconsciousness deepening to coma. With the exception of the liver, the organs showed no particular change accountable for these symptoms. The liver in five out of the eight cases was markedly fatty—of a uniform pale fawn or buff colour, studded on section with pale purple spots around the intralobular veins. Microscopically, the liver cells were filled with fat, most abundant in the periphery of the lobule—the condition seeming to be one of extreme fatty infiltration rather than of fatty degeneration. Neither macroscopically nor microscopically did the appearances resemble those of acute yellow atrophy. The conclusions which he drew as to the cause of death were: (1) that the death was due to auto-intoxication; (2) that a fatty condition of the liver with functional disturbance existed before the operation; and (3) that chloroform and shock combined aggravated this fatty condition and thus loaded the system with alkaloids.

Dr. Guthrie's conclusions and views, as he states, did not meet with acceptance—the fatalities were held to be due to carbolic acid poisoning or to pulmonary embolism. In 1903 he published a second series of four fatal cases, three of them in children in which he was able to exclude carbolic acid and fatty embolism as the cause of death which he attributed to the action of chloroform on a morbidly fatty liver.

PATHOGENESIS.

The above pathological changes correspond with those that can be produced experimentally by chloroform and ether.[1] On comparing sections of the liver removed before and after chloroform anæsthesia, Stiles and McDonald found that while the former showed little or no fatty change, in the latter such changes were extreme. After administration of ether these changes were slight in comparison. Both in man and in animals individual idiosyncrasy must be held to play an important part to account for the fatalities in individual cases. According to Guthrie the unknown cause of this idiosyncrasy is a pre-existent and morbidly fatty condition of the liver which reduces the liver to the verge of inadequacy prior to the administration of the anæsthetic. Such a condition, it is pointed out, is common in rickety and poorly nourished children among whom this class of poisoning has been most frequently observed, and is doubtless aggravated by the cyclical vomiting accompanied by acetonuria so often met with in children to which Guthrie draws attention, and the symptoms of which, as shown by Brackett, Stone, and Low, are practically the same as those of a minor degree of post-anæsthetic poisoning. In the few cases of fatal cyclical vomiting in which a necropsy has been obtained the liver, kidneys, and other organs have shown fatty and degenerative changes precisely similar to those met with in cases of delayed anæsthetic poisoning. (Griffith, 1900; Langmead, 1905.) On the strength of these similarities Guthrie emphasises this fatty change in the liver and the acid intoxication which accompanies it as the determining factors responsible for the symptom-complex of this condition. The conditions in which it is likely to be met with are such as are known to be associated with fatty liver—e.g., sepsis, acute and chronic, rickets, and infantile paralysis which have been treated by over-fattening and under-exercise; probably also conditions such as alcoholism and certainly starvation and cyclical vomiting with acetonuria. In favour of the view that disturbance in fat metabolism plays some part in the pathogeny of this condition is the fact that acetonuria is a common sequel after anæsthesia. (Becker, 1905; Abram Hill, 1896.) Abram Hill found it in 64 per cent. of cases, while Becker found that it was regularly produced in healthy subjects, especially in children.

To connect the symptom-complex of post-anæsthetic poisoning exclusively with disturbances in fat metabolism is, in my opinion, to exaggerate the importance of this change, and to under-estimate the importance of the other functional liver disturbances with which disturbance in fat metabolism is associated. As I have shown,[2] the acidosis accompanying increased fat metabolism becomes of grave pathogenetic significance when combined with diminished proteolytic activity, owing to inanition, deprivation of food, or recurrent vomiting. As the result of the diminished absorption of ammonia in the portal blood caused by such conditions the intracellular alkalinity of the liver cell is already at a low level. There then results first of all a serious interference with the proteolytic, antitoxic, and glycogenic functions of the liver (of which the post-anæsthetic sickness is a symptom) and the transference of fat to the liver in increased quantity from its depôts is a result. The acidosis which accompanies this increased fat metabolism depresses still further the intracellular alkalinity and proteolytic and antitoxic powers to the point when they are almost in abeyance. There then ensue the characteristic severe toxic cerebral symptoms of the condition which rapidly prove fatal.

On this view it will be seen that the disturbances in fat metabolism, evidenced by the fat changes after death and the acetonuria and acidosis during life, are thus, I consider, largely the results—not necessarily the causes—of the preceding disturbances in the other functions (proteolytic, antitoxic, and glycogenic) of the liver. To connect the striking and overwhelming symptoms of post-anæsthetic poisoning with fat metabolic disturbances alone is to overlook their most striking feature—viz., their toxic cerebral features. As I shall now show, the acidosis of fat metabolism becomes really important when it is combined with disturbance in proteolytic activity and glycogenic activity of the liver cell. This is the condition presented in the final stages of severe liver disease such as cirrhosis, in acute yellow atrophy, phosphorus poisoning, and chloroform poisoning.

DISTURBANCES CONNECTED WITH GLYCOGENESIS.

The functions of the liver in relation to the storage and distribution of the carbohydrates of the food are only second in importance to those discharged by it in relation to protein metabolism. The functional disturbances connected with glycogenesis manifest themselves: (1) *directly* by disorders—e.g., glycosuria and diabetes—connected with carbohydrate metabolism, absolute or relative efficiency of the liver in dealing with the carbohydrate material supplied to it in the food, or conveyed to it in the tissues; and (2) *indirectly* by effects which such disturbances have on the metabolism of fats and of proteins. The most obvious effect of the first class of disturbance is glycosuria. The effects of the latter show themselves by disturbances of fat metabolism or by disturbances of proteolytic and antitoxic functions.

Indirect effects of disturbance of glycogenesis on fat metabolism and proteolysis.—When carbohydrate metabolism is out of order the synthesis of fat is also disordered. For it is an important rôle of the body to synthesise fat from the carbohydrate which is not at once used up or converted into glycogen. Hence, next to fat carbohydrate is the most powerful fat-producer—a fact now definitely ascertained and

NOTE UPON THE TUBERCULO-OPSONIC INDEX OF THE URINE AND SWEAT IN HEALTH AND IN TUBERCULOUS DISEASE.

BY JAMES MILLER, M.D. EDIN.

ANYONE engaged in opsonic work cannot fail to have been struck by the marked variations in the opsonic index from day to day in the case of tuberculous patients in particular. Reference to Chart 1, which is a portion of a record extending over a period of several months, conveys at a glance the marked variations in the tuberculo-opsonic index which occur even in a moderately early case of pulmonary tuberculosis—a case looked upon as curable. Again, to take a surgical case—one with considerable abscess formation. The day preceding the date of operation the tuberculo-opsonic index was found to be 0·8; the day after operation the index was 2·8; two days later it was found to have fallen to 1·0; and on the fourth day after operation it stood at 1·1. In thinking over this matter the question spontaneously arose in my mind, How is this difference to be accounted for? What has become of the quantity of anti-bacterial substance in the blood which is represented by the difference between the indices of 2·8 and 1·0? It was with the object of endeavouring to acquire some light upon this point that I proceeded to make the following observations upon the opsonic index of the urine and blood serum of a healthy person and of one who was suffering from chronic pulmonary tuberculosis, and supplemented them by making a few observations on the opsonic index of the sweat in other acute cases of the same disease. At the outset I encountered the difficulty in obtaining estimates of the opsonic content of urine of high specific gravity which Wright had previously noted in working with salt solutions of high concentration—viz., the elimination of phagocytosis either to a large extent or completely. Therefore, when the specific gravity of the urine was higher than 1008 it was found *necessary to reduce it to that figure before* the opsonic content could be accurately measured. The figure, 1008, was taken as being approximately the specific gravity of normal saline solution. This reduction of the specific gravity can be done in either of two ways. In the first place one may add a sufficient quantity of distilled water to reduce it to the required level (1008), a method of reduction which is open to the disadvantage that it also reduces the opsonic value of the fluid. In the second place, the specific gravity may be reduced by dialysis, by which means practically the whole of the salts and urea may be removed (by this method the amount of urea present was reduced to 0·1 per cent. to 0·05 per cent.). Both methods were employed and as the results which they yielded differed materially it has been thought desirable to record both.

My first observations were made upon the urine and blood serum of a healthy person, the urine being prepared by dilution, and in a smaller number of instances by dialysis. In Chart 2 is shown a record of the observations made. It shows (1) the specific gravity of the urine each day before reduction; (2) the opsonic content of the reduced urine, indicated by the interrupted line; and (3) the opsonic content of the blood serum indicated by the straight line at 1. The points which arrest attention are firstly the considerable quantity of tuberculo-opsonic substances in the urine, indeed (if we take into account the fact that the sample of urine had been diluted in many instances by more than twice its bulk) the opsonic content of the urine frequently greatly exceeds the proportion contained in the blood serum; and secondly, that the *amount of opsonin* in the urine was subject to considerable fluctuations. The next step was to note the opsonic index of samples of the same urine which had been dialysed. The results of such examinations also appear on Chart 2 marked by an encircled dot. We are in this way in a position to compare the opsonic indices of the blood serum, of the diluted urine, and of the dialysed urine of the same day in a series of occasions. On one occasion—day 43—the difference is very marked, the diluted urine giving an index of 1·2 while the dialysed urine gave an index of 3·66.

Pursuing the same line of investigation I next employed the urine and blood serum obtained from a person suffering from pulmonary tuberculosis (chronic fibroid form), the comparison being made with the same healthy standard as was employed in the first case represented by line 1. And for the benefit of those who may note that the opsonic curve of the blood serum is not by any means typical of a case of chronic tuberculosis it may be stated that the index in this case had previously been raised by a series of inoculations of tuberculin guided by systematic observations of the opsonic index of the blood. Taking our facts in the same order we note in Chart 3 the evidence obtained from diluted urine: firstly, that the opsonic index of this urine, unlike

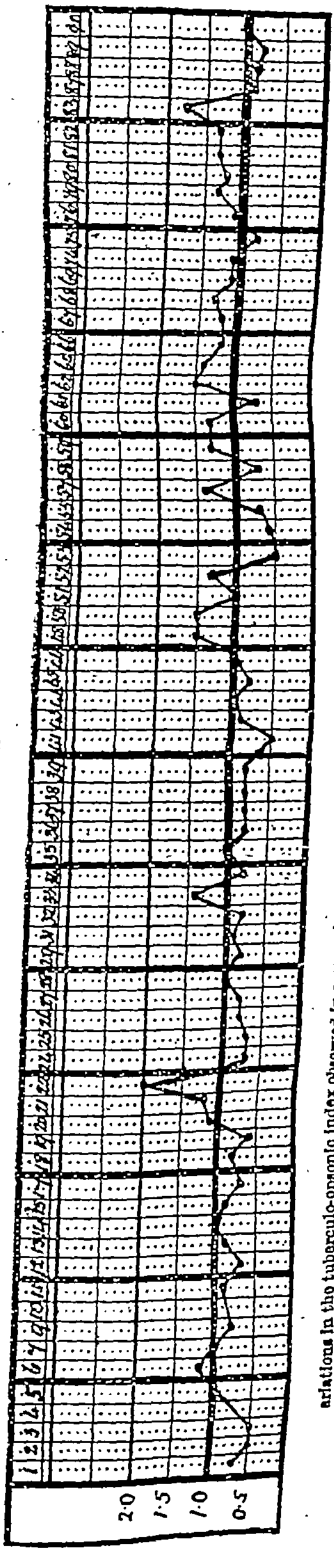

CHART 1.

ariations in the tuberculo-opsonic index observed in a case of pulmonary tuberculosis undergoing sanatorium treatment without the employment of vaccine.

acids is the fat of the body. In general it must be emphasised that an increase of the fat in food has no material influence on the formation and elimination of the acetone bodies. This depends in the first place upon the internal condition of the cell, and this condition is affected by a deficiency of carbohydrates (and therefore in the liver by deficiency of glycogen). The extent to which the metabolism of fats is affected in diabetes and diabetic coma may be judged from the fact that no less than 342 grammes have been found in the urine in the course of three days (Magnus Levy). The fats therefore yield the chief material necessary for the formation of acetone bodies and their formation in any notable quantity is in the first place caused by lack of carbohydrates. They are not formed in the intestine. They may possibly be formed in all organs but the chief seat of the formation is the liver and muscles.

Disturbances in hepatic fat metabolism are thus largely connected with deficiency of glycogen whether arising from want of carbohydrates (as in starvation) or from excessive loss of sugar (as in diabetes). The conditions in which increased acidosis arises are those especially affecting glycogenesis, such as poisoning with carbonic oxide, extirpation of the pancreas, poisoning with phloridzin, chloroform, exclusive feeding on animal fats, and lastly severe cases of diabetes.

Disturbances of Proteolytic and Antitoxic Functions.

The symptoms vary according to the degree with which the proteolytic functions are affected simultaneously.

1. If these latter are fully maintained the symptoms produced in severest cases are those of diabetic coma. In these conditions, owing to the absolute deficiency of carbohydrate and the excessive movement of fat from the tissues to the liver the acidosis is absolutely excessive. The proteolytic functions of the liver are, however, fully maintained.

2. The chief effect of such disturbances of fat metabolism arises when an acidosis of lesser degree is combined with disturbance of proteolytic activity of the liver cell. This is the condition presented in the final stages of severe liver disease such as cirrhosis, acute yellow atrophy, phosphorus poisoning, or chloroform poisoning. A disturbance in fat metabolism (with increased acidosis) which would not affect a fairly healthy liver cell becomes then much more important. At a time when the intracellular alkalinity of the liver cell is already at a low level (owing to inanition, deprivation of food, and diminished absorption of ammonia in the portal blood consequent thereon) the additional acidosis arising from excessive fat metabolism may, as already described, suffice to lower the alkalinity below the point necessary to keep its own digestive proteolytic ferments in check. There then results auto-digestion or autolysis of the liver cell by its own ferments, with complete arrest of all its functions. The clinical picture then presented in slighter or severe degree is not that of acidosis, as in diabetic coma, but that of acute yellow atrophy and chloroform poisoning—viz., essentially one due to the abolition of all the antitoxic functions of the liver. The symptoms largely resemble those produced when the portal blood is conveyed directly into the general circulation by means of an Eck's fistula.

Conclusion.

This conclusion which one thus reaches as to the relation of disturbances in fat metabolism to the severest forms of liver disturbance represented by acute yellow atrophy and chloroform poisoning is, in my judgment, of great practical importance. The vomiting which occurs after administration of anæsthetics is not of nervous origin; but it is, I consider, essentially toxæmic, due to the profound depression of liver function with consequent diminution in its antitoxic function during the period of the administration. This depression will be the greater if a liver already weakened by disease or by poor nutrition be further unduly weakened by food having been withheld for many hours before the administration. This enforced abstention from food before administration of an anæsthetic may thus in individual cases be carried too far, and it is, in my opinion, largely responsible for the fatal effects of delayed chloroform poisoning in exceptional cases. Such effects could in all probability be completely prevented if, instead of withholding food, particular care was taken that the patient had always a very nutritious and easily digestible meal, well-sweetened, two or three hours before the operation.

Harley-street, W.

OBSERVATIONS ON THE BACTERIOLOGY OF SCARLET FEVER.

By HAROLD KERR, M.D. EDIN., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER OF HEALTH OF THE CITY AND COUNTY OF NEWCASTLE-UPON-TYNE.

THE following are the results of an investigation of the organisms present in the throats, noses, &c., of a series of 160 cases of scarlet fever admitted to the wards of the Bury and District Joint Hospital during the years 1906–07, together with an examination of the throats of 40 healthy individuals.

Throat.—The first step was the general classification of organisms found in cultures on blood serum from swabs taken from the pharynx and fauces; in the case of the hospital patients these were made immediately on admission. The colonies which appeared included streptococci, diplococci, staphylococci, bacilli, and yeasts in various combinations, and their frequency was as follows:—

Organism.	Scarlet fever.	Healthy.
Streptococci	134, or 84 per cent.	33, or 83 per cent.
Diplococci	125, or 78 ,, ...	35, or 88 ,,
Staphylococci	93, or 61 ,, ...	19, or 48 ,,
Yeasts	16, or 10 ,, ...	3, or 8 ,,
Bacilli	77, or 48 ,, ...	20, or 50 ,,
Bacillus of Klebs-Löffler	14, or 9 ,, ...	—

Among the "bacilli" are included all forms of "diphtheroid," only the true diphtheria bacillus being separately classified.

In this list the close correspondence between the two columns is very striking, the only point of marked difference being the more frequent occurrence of staphylococci and diphtheria bacilli in scarlet fever. In none of these patients was there any clinical sign or symptom of diphtheria.

Nasal discharge.—During the same period the purulent nasal discharge was examined in 67 cases of scarlet fever and there were found:—

Streptococci	in 28,	or	42%
Diplococci	,, 34,	or	51%
Staphylococci	,, 50,	or	75%
Yeasts	,, 1,	or	2%

Bacilli	in 41,	or	61%
Bacillus of Klebs-Löffler	in 25,	or	37%

Here the diphtheria bacillus occurred more frequently than in the throat, while streptococci were less frequent and staphylococci more frequent.

Ear discharge.—The ear discharge was examined in 17 cases of scarlet fever, with the following result:—

Streptococci	appeared in	7, or 41%
Diplococci	,,	,, 10, or 59%
Staphylococci	,,	,, 11, or 65%
Yeasts	,,	,, none.

Bacilli	appeared in	8, or 47%
Bacillus of Klebs-Löffler	appeared in	5, or 29%

Thus streptococci and diplococci occurred in much the same proportion of cases in the ear as in the nose, and in considerably less than in the throat, while staphylococci were more frequent than in the throat and less frequent than in the nose. The diphtheria bacillus was relatively much more common than in the throat, though not quite so common as in the nasal discharge.

Pus.—On opening a cervical gland abscess in six cases the pus gave a pure culture of streptococci in each, as also in two cases in which the pus was obtained from the mastoid antrum.

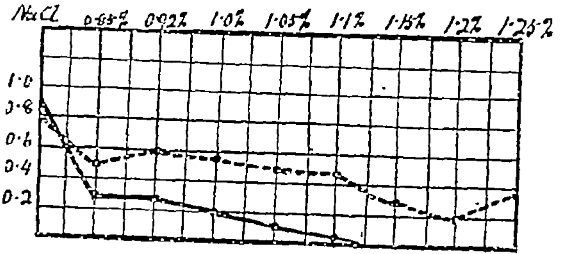
Blood.—Cultures (both solid and liquid) were made from the blood of six cases on the second day of the disease and a streptococcus with chains of from six to ten individuals was obtained from one, a diplococcus without chain formation from another, while the remaining four gave no growth.

The occurrence of streptococci in pure culture in so true secondary conditions as the adenitis and mastoid infections, taken together with the frequency of their occurrence in the throat, is strong evidence that they play an important etiological part in at least the secondary symptoms of scarlet fever.

Examination of streptococci by Gordon's tests.—The next step undertaken was a full and detailed examination of the streptococci obtained from scarlet fever cases (chiefly from the throat, but also from the nose, ear, and mastoid) and from the throats of healthy individuals and others suffering

In attempting to draw conclusions from the foregoing observations it might reasonably be objected that these excretions which were examined did not contain opsonic substances but that the results obtained were due entirely to spontaneous phagocytosis. With the object of ascertaining to what extent this objection was founded the following further experiments were undertaken. In a paper read before the Royal Society Wright indicated a method by which spontaneous phagocytosis may be eliminated—viz., by the use of salt solutions of high concentration. That method has been adopted to meet the objection which might be raised in the present instance. The experiments were conducted as follow.

CHART 5.



Dialysed heated urine. Dotted line, tuberculous urine; continuous line, healthy urine.

Influence of the salt content (of the fluid environment of the leucocyte) upon the tuberculo-opsonic index of heated urine.—The urine was first heated at 60° C. for ten minutes, cooled, and then diluted to a specific gravity of 1008. Phagocytic counts were obtained from films prepared from phagocytic mixtures containing a double volume of diluted (or dialysed) heated urine, a double volume of washed corpuscles, a single volume of tubercle bacilli suspension (in 0·85 per cent. NaCl solution), and in each case a single volume of a solution of sodium chloride of progressively increasing strength. Charts 4 and 5 and Tables I. and II. show the results obtained (*a*) with diluted heated urine and (*b*) with dialysed heated urine. In each instance normal healthy urine and urine from tuberculous subjects are compared.

TABLE I.—*Tuberculo-opsonic Indices. Results obtained with Diluted Heated Urine.*

Salt (NaCl) content of the phagocytic mixtures.	Normal urine of specific gravity 1025, heated for ten minutes at 60° C., then cooled, and *diluted* to specific gravity 1008.	Pooled urine (of nine tuberculous patients) of specific gravity 1020, heated for ten minutes at 60° C., cooled, and *diluted* to specific gravity 1008.

TABLE II.—*Tuberculo-opsonic Indices. Results obtained with Dialysed Heated Urine.*

Salt (NaCl) content of the phagocytic mixtures.	Normal urine of specific gravity 1025, heated for 10 minutes at 60° C., then cooled, and *dialysed* of nearly all its salts and urea.	Pooled urine (of nine tuberculous patients undergoing tuberculin treatment) of specific gravity 1020, heated for ten minutes at 60° C., cooled, and *dialysed* of nearly all its salts and urea.
0·56 per cent.	0·9	0·8
0·85 "	0·3	0·5
0·925 "	0·3	0·6
1·0 "	0·2	0·56
1·05 "	0·1	0·5
1·1 "	0·06	0·5
1·15 "	—	0·3
1·2 "	—	0·2
1·25 "	—	0·35

It seems to be abundantly evident from the foregoing observations and experiments that the excretions—urine and sweat—contain anti-bacterial or bacteriotropic substances. Why such important substances should be thrown out in the excretions is a difficult problem, unless it be that being specific and not required in the ordinary functions of the cells of the body, they are therefore eliminated as foreign substances.

For the supply of clinical material required for the work of this paper my thanks are chiefly due to Dr. David Lawson, of Nordrach-on-Dee.

Glasgow.

OBSERVATIONS ON THE OPSONINS, WITH SPECIAL REGARD TO LUPUS VULGARIS.

BY A. REYN,
OF THE FINSEN MEDICAL LIGHT INSTITUTE, COPENHAGEN;
AND
R. KJER-PETERSEN, M.D.,
ASSISTANT PHYSICIAN AT OERESUNDSHOSPITALET, COPENHAGEN.

(*Concluded from page 928.*)

PART II.

IN the first part of this paper the general principles of opsonic determination were considered. We shall now proceed to describe a series of cases of lupus in the treatment of which tuberculin vaccinations were employed regularly.

I.—*Cases of Long Standing.*

CASE 1.—L. W. (Curve 11). The patient was an unmarried man, 20 years of age, whose brother also suffered from lupus vulgaris and was cured by the Finsen treatment. The patient had suffered from lupus for six years, and had been treated with ointments and freezing with chloride of ethyl until five years ago when he was admitted into the Finsen Light Institute, and from 1902 to 1906 was there treated with a total of 860 sittings. The mucous membranes were treated with the galvano-cautery. In spite of these energetic measures the disease relapsed constantly, became more extended, and assumed a malignant type; we therefore at the close of 1906 stopped the light treatment. On Feb. 9th, 1907 his condition was as follows The whole nose, with the exception of the root, was much swollen, and presented fungous nodules, several of which were ulcerated. There was only a small defect. The affection extended two centimetres on both cheeks. On the left cheek near the corner of the mouth there was a large ulcer measuring 3 by 1½ centimetres; there was also a smaller ulcer near the right corner. The upper lip was scar-like. The prolabium was partly destroyed by an ulceration which extended on the mucous membrane. There were extensive ulcerations in the vestibulum on both sides and on the mucous membrane in the nasal cavity On the soft palate there was a small granulation. The mucous membrane of the pharynx was swollen but not distinctly ulcerated. The epiglottis was scar-like but the edge was swollen and ulcerated. There was swelling of the plicæ aryepiglotticæ, and there were small ulcerations on the plicæ ventriculares. The lungs were normal. T.R. treatment was commenced. The dates of the injections of T.R. and the doses were as follows (the fractions represent parts of a milligramme): Feb. 9th, 1/4000; March 3rd, 1/4000; March 15th, 1/2000; March 26th, 1/2000; April 9th, 1/500; April 22nd, 1/250; May 13th, 1/250; June 4th, 1/250; July 13th, 1/250; August 7th, 1/250; and August 23rd, 1/250; making a total of 11 injections. Sept. 9th: The disease had since the beginning of the treatment become distinctly worse, and was now worse than ever. The nose was affected *in toto* with confluent ulcers on both alæ and on the tip. The affection had extended into the left corner of the eye and on the left upper eyelid. On the cheeks it had spread two centimetres further sideways. At both corners of the mouth and on the upper lip there was a widespread ulceration. The ulcers in the cavity of the nose had also extended further. On the soft palate there were small ulcers which were spreading on the arches of the palate and on the wall of the pharynx. The state of the throat remained as it was on Feb. 9th. The lungs were normal. The urine was normal.

CASE 2.—H. J. (Curve 3). The patient was an unmarried man, 24 years old, who had been suffering from lupus vulgaris for eight years. He was admitted into the Finsen Light Institute seven years ago and was treated from 1900 to 1906 with 1126 sittings. The mucous membranes were treated with the galvano-cautery. The affection several times got better, but relapses occurred constantly and a fistula was established from the left vestibulum through the tip of the nose; this fistula did not heal up in spite of energetic treatment, and nodules constantly made their appearance in the circumference and on the cheeks. On March 3rd, 1907, there was on the nose only a little infiltration, but there were scars and considerable defect of the apex and the right ala nasi. On the tip of the nose there was a perforation into the nasal cavity, and in the circumference of this perforation there were some partly ulcerated small nodules. On the right cheek there was one nodule and on the left cheek there were four nodules. Behind the corner of the mouth there was a patch measuring 2 by 1 centimetres, with nodules. Behind the mandible on the left side there were two scrofulous ulcers. In the nasal cavity there were extensive ulcers. The lungs were normal. The urine was normal. Light treatment was given up. On March 3rd T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; March 15th, 1/2000; April 8th, 1/1000; May 13th, 1/500 from catarrhal and diphtheritic affections. In all 200 specimens were taken from the following sources for comparison. I. 100 separate specimens from 27 scarlatinal patients, viz.:—80 specimens from 26 different throats, 6 from 2 different noses, 8 from 2 discharging ears (different patients), and 6 from 2 different cases of mastoid infection. II. 50 specimens from 20 different healthy throats. III. 50 specimens from 12 cases of other diseases, not scarlet fever—viz: 30 specimens from 6 different diphtheria throats, 13 from 5 different catarrhal throats, and 7 from 1 case of follicular tonsillitis with abscess formation. Swabs were taken from each case and nasgar plates inoculated from them and incubated at 37° C. for 24 hours.

The resultant colonies were then examined macroscopically and under the low power; subcultures of different colonies were made in lemco bouillon at 37° C. for 48 hours, and the growth examined macroscopically and microscopically. On finding streptococci in the bouillon, these were re-subcultured after Mervyn H. Gordon's method[1] in the following media: (1) Litmus milk; lemco-litmus broth containing (2) saccharose, (3) lactose, (4) raffinose, (5) inulin, (6) salicin, (7) mannite, and (8) potassium nitrate, all in 1 per cent. solution, and (9) neutral red broth, the last anaerobically in Buchner's tubes, all at 37° C.; and (10) on gelatin at 20° C. Coniferin was unfortunately unobtainable either in the home or foreign market. Incubation of the subcultures was maintained for seven days and record then made of the decomposition of the various sugars from the colour of the media, &c. As far as possible the investigation was made to correspond, for the sake of commparison, with that of Dr. F. W. Andrewes and Dr. T. J. Horder, described in THE LANCET of Sept. 15th, 22nd, and 29th, 1906.

Taking into account only the morphological differences between individual specimens as seen in the growth in bouillon, the following classification may be made according to the length of the chains, percentages alone being stated:—

Chains.	Healthy.	Scarlet fever.	Other conditions.
Longissimus (Liss)	8	20	18
Longus (L.)	34	48	38
Medius to Longus (M. to L.)	14	14	10
Medius (M.)	22	8	8
Brevis to Medius (B. to M.)	2	—	—
Brevis (B.)	4	1	—
Conglomeratus (C.)	16	9	26

The longer forms of streptococci then appear to be relatively more numerous in the diseased than in the healthy conditions, the short forms appearing relatively more numerous in the healthy throats. The results pointed to what Andrewes and Horder[2] referred to as a replacement of the common short forms by long varieties quite early in the disease. It will be noticed that the conglomerate forms, described by Gordon as being peculiar to scarlet fever, were found much less frequently in scarlet fever than in health, and very much less frequently than in other catarrhal conditions of the throat.

In classifying the specimens the method adopted by Andrewes and Horder was as closely adhered to as possible. Macroscopically the appearances were generally similar to those noted by the same observers. The accompanying large table summarises the results obtained from the subcultures, arranged on the system suggested by Andrewes and Horder. Where one of the present series corresponds with one of theirs, their classification (Group and Variant) numbers are indicated in italics, and also their result with the coniferin broth medium in brackets. Decomposition of the media is indicated in the table by a positive (+) sign and no visible reaction by a negative (—). Two points of importance which do not appear in the table are: (1) that two or more specimens from a single case often differ from one another in only a single reaction; and (2) that no coincidence was found in any scarlet fever case between organisms obtained from the ear when discharging or from the mastoid antrum and any that were obtained from the throat. In one case an organism was obtained from the nasal discharge which gave the same reactions as one of those found in the throat. It will be seen that out of 200 specimens 64 variants were obtained.

The following table shows the different distribution of the variants (percentages only) in the groups suggested by Andrewes and Horder:—

Group.	Healthy.	Scarlet fever.	Other diseases.
I.	20	10	14
II.	8	1	2
III.	58	87	80
IV.	14	2	4

It is obvious that very little can be learnt for purposes of diagnosis from these results, taking the reactions in their series. Subjoined is a table of percentages comparing the reactions of organisms from the different sources to the individual tests, and it is also obvious that they are equally valueless for the purpose. Mannite alone is more readily decomposed by organisms from healthy throats than from diseased, but there is no test among them by which scarlet fever can be distinguished from the other diseases.

Test.	Healthy.	Scarlet fever.	Other diseases.
Milk pink	78 per cent.	88 per cent.	92 per cent.
Milk clot	68 "	83 "	84 "
Neutral red	22 "	48 "	54 "
Saccharose	86 "	92 "	90 "
Lactose	72 "	68 "	72 "
Raffinose	50 "	34 "	20 "
Inulin	6 "	12 "	12 "
Salicin	34 "	33 "	32 "
Mannite	14 "	2 "	4 "

With a much smaller number of specimens of streptococci (33) from scarlet fever cases, Andrewes and Horder obtained results with which the above correspond most strikingly. As a means therefore of diagnosis in scarlet fever, Gordon's tests must be regarded as of little value in the present state of our knowledge of the etiology of the disease. If the tests are of real differential worth for the various strains of streptococci—and the remarkable constancy shown by different generations of individuals to them, in my own experience, indicates that they are—we find ourselves faced by the fact that they fail absolutely to point to any particular strain as being even more frequently present in scarlet fever than in other catarrhal and inflammatory conditions of the throat. That the infecting agent is present in the pharyngeal and faucial mucus is absolutely all that has been established for certain regarding the causation and source of the disease. If none of the streptococci in the throat are causative of the primary condition some other agent must have made it possible for them to obtain entrance to the tissues in order to produce the secondary complications. It was shown above that the staphylococci are relatively increased in scarlet fever. Possibly a careful examination of these, on similar lines to that described for the streptococci, might reveal something of importance.

I am indebted to Dr. A. E. Brindley, medical superintendent of the Bury and District Joint Hospital, for permission to publish the above.

Newcastle-upon-Tyne.

UNIVERSITY COLLEGE HOSPITAL.—The annual general meeting of the supporters of this hospital was held on March 26th, under the presidency of Mr. Henry Lucas, treasurer to the charity. The report on the work of the hospital during the past year stated *inter alia* that owing to lack of means the committee has been unable to open a ward containing 24 beds which should be available for the sick poor; in other words, about 350 patients annually, many requiring immediate treatment in the wards, have to be refused admission. An additional annual expenditure of about £1200 would be required to keep the ward open, and the committee has not felt justified in incurring this further liability, when in order to meet the deficiency in income it has had to trench upon its small invested funds by the realisation of £1500 Consols, and this notwithstanding that it has had to devote to purposes of current expenditure legacies which in more prosperous times could have been invested. The committee urgently appeals to the benevolent to do their utmost to relieve it from the financial anxieties and difficulties with which it is constantly faced, as it is obvious that only by strenuous efforts on the part of everyone interested in the welfare of the hospital can its efficiency be maintained.

CURVE RELATING TO CASE 4.

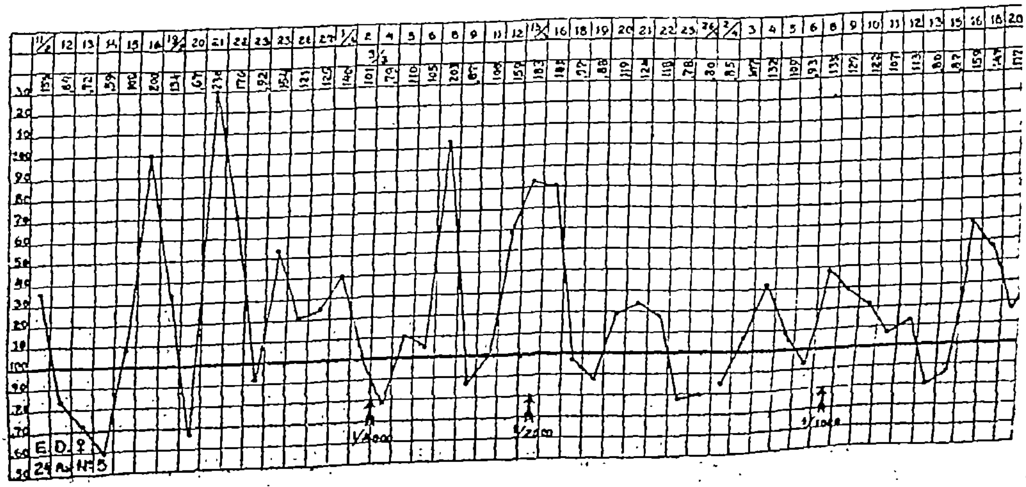

CHART 2.

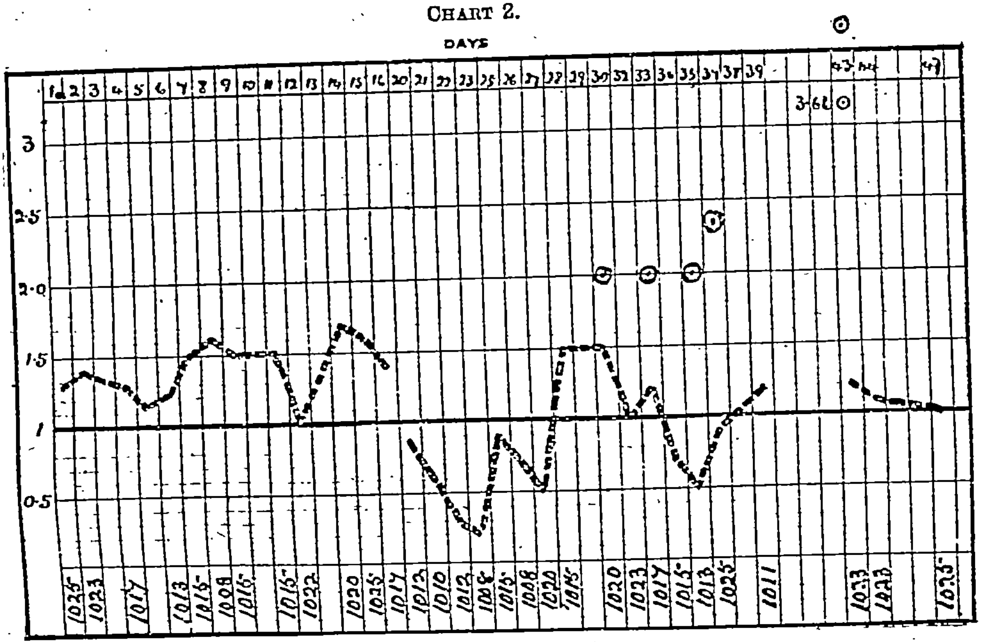

Opsonic chart of urine in health.

CHART 3.

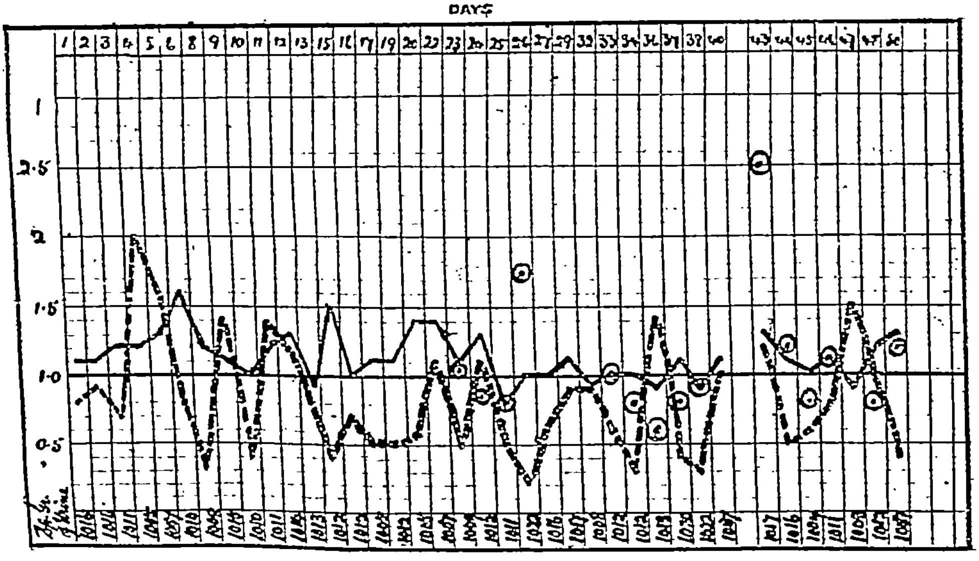

Chart comparing opsonic indices of serum (continuous line) and urine (interrupted line) in a case of chronic fibroid pulmonary tuberculosis.

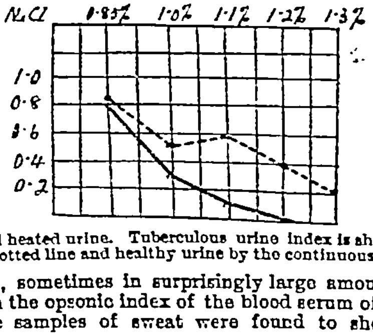
that of the healthy person's urine, was usually found to be lower than that of the blood (out of 50 estimations there are only six exceptions); secondly, that it was for the most part lower than the opsonic index of a healthy person; and thirdly, that frequently a rise in the opsonic index of the patient's urine was associated with a fall in the opsonic index of the blood serum and *vice versâ*. This feature was present in 20 out of 50 consecutive observations. When the urine was dialysed and then examined the same phenomenon—viz., rise in the opsonic index—was present as had been remarked previously in the case of the healthy person, with this difference, that the rise was not nearly so marked nor so constant as in the case of the healthy individual.

Having been prevented from pursuing my inquiry in regard to sweat so far as I had intended, the data need not be set forth in detail. It may be sufficient to record that a number of observations on the sweat of persons suffering from acute pulmonary tuberculosis has been made and that the samples were in every instance found to contain tuberculo-opsonic substances, sometimes in surprisingly large amount. Compared with the opsonic index of the blood serum of a healthy person the samples of sweat were found to show indices ranging from 0·8 to 1·3.

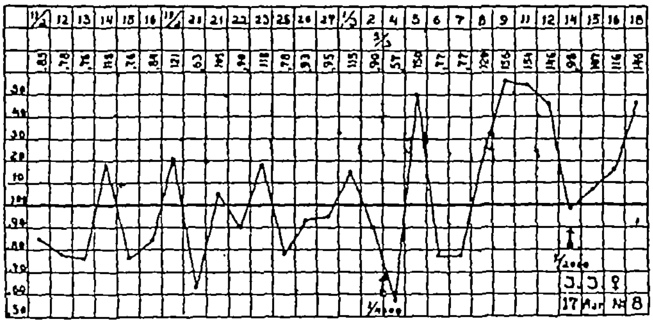
CHART 4.



Diluted heated urine. Tuberculous urine index is shown by the dotted line and healthy urine by the continuous line.

The cavity of the nose was not affected. On the hard palate there was one large and deep ulcer measuring two centimetres in length and breadth. March 3rd: The ulcer on the palate remained as before in spite of the galvano-cautery. T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; and March 14th, 1/2000; making a total of two injections. On March 14th the patient left the institute for economical reasons. On June 7th on the soft part of the nose there were a few nodules and in the cavity of the nose there were widespread ulcers. The ulcer in the palate was larger; it now occupied the whole hard and soft palate extending on the uvula and the arch of the palate. There were widespread ulcers on the gum of the upper jaw.

CURVE RELATING TO CASE 8.



II.—*Fresh and Mild Cases.*

CASE 9.—E. L. (no Curve). The patient was a boy, seven years old, who had been suffering from lupus vulgaris for six months. He had not been treated before. Admitted to Finsen Medical Light Institute on May 31st, 1907. On the right cheek there was in the middle a round, pale-red patch (two centimetres in diameter), slightly prominent, with an uneven surface, and fine desquamation. There were no distinct nodules. On the right eyebrow there was a patch, three centimetres long and three-quarters of a centimetre broad, of the same type as that on the cheek. Excised portions of tissue showed under the microscope typical indications of lupus. There were no other tuberculous affections. The lungs were normal; the urine was normal. On June 11th T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: June 11th, 1/2000; July 1st. 1/2000; July 24th, 1/2000; and August 19th, 1/2000; making a total of four injections. Sept. 3rd: On the right cheek there was a patch measuring two centimetres in diameter with numerous typical nodules. The patch on the right eyebrow remained as on May 31st. The lungs were normal; the urine was normal.

CASE 10.—A. J. (no Curve). The patient was an unmarried woman, 20 years of age, who had been suffering from lupus vulgaris for one month. She had not been treated before. Admitted to Finsen Medical Light Institute on June 22nd, 1907. The soft tissues of the nose were red and swollen with two distinct nodules. There were widespread ulcers in the cavity of the nose. The lungs were normal. The urine was normal. On July 26th T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: June 26th, 1/800; July 17th, 1/500; August 7th, 1/500; and August 23rd, 1/500; making a total of four injections. The cavity of the nose was at the same time treated with the galvano-cautery. By July 29th the nodules had grown bigger, and by Sept. 2nd the affection was much greater. The soft tissues of the nose were a good deal swollen, with two ulcers of the size of a pea and numerous nodules. In the cavity of the nose the ulcers were much smaller. The lungs were normal. The urine was normal.

CASE 11.—A. F. (no Curve). The patient was a married woman, 29 years old, who had been suffering from lupus vulgaris for one year. She had been treated with ointments without effect. Admitted to Finsen Medical Light Institute on July 6th, 1907. On the right side of the tip of the nose there was an ulcer of the size of a hempseed in the circumference of which there were infiltration and solitary typical nodules. In the cavity of the nose there were widespread ulcers. There were no other tuberculous affections. The lungs were normal. The urine was normal. On July 6th T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: July 6th, 1/1000; July 29th, 1/1000; and August 23rd, 1/500: making a total of three injections. The cavity of the nose was treated with the galvano-cautery. By July 29th the affection had grown bigger and there were several prominent nodules. On Sept. 2nd on the right side of the tip of the nose there were confluent nodules (a patch measuring 2 by 1¼ centimetres) with rather pronounced infiltration. The cavity of the nose had healed up. The lungs were normal. The urine was normal.

The results of the sole treatment with T.R. has, as it appears from the above histories, been very bad. When we are going to consider at first the eight patients who were treated before with Finsen light we must exclude Case 7, for this patient died before any effect of the T.R. could be expected. Case 8 received only two injections and then went home. On her return three months afterwards her condition was much worse. Concerning the other six patients, the very widespread affection in Case 4 remained stationary, while the disease of the five other patients spread during the T.R. treatment. The three fresh cases did not give better results. One of them (Case 9) remained stationary while the other two became very much worse. We could not in any of the cases see any improvement at all following treatment according to Wright's method. In the most fortunate cases the affection remained stationary; in most of the cases it became worse. We wish especially to call attention to the fact that in two out of the three fresh cases the disease spread remarkably quickly during the T.R. treatment. We therefore feel bound to dissuade practitioners from employing this method as a *sole treatment* for lupus vulgaris both in old cases and in fresh and apparently benignant cases.

Besides the observations just mentioned (with T.R. as sole treatment) we have in the case of some patients used light treatment and T.R. together to get an idea of the value of a combination of these two treatments. In this way we have treated altogether four patients whose histories follow here.

CASE 12.—A. M. (Curve 4). The patient was a girl, 14 years old, who had been suffering from lupus vulgaris for eight years. She had been treated with ointments. Admitted to Finsen Medical Light Institute on Oct. 15th, 1906. On the nose and on the foremost part of both cheeks there were numerous nodules and rather deep infiltration. The affection extended from the angles of the mandible down into the submental region where there were numerous nodules. On the lips and chin there were many nodules. On the right upper eyelid there were a few nodules. There was no other tuberculous affection. The lungs were normal. The urine was normal. Light treatment. From Oct. 5th, 1906, to Sept. 21st, 1907, the patient had 185 sittings. Feb. 1st, 1907: There had been steady improvement. The nodules were fewer and smaller. Light treatment was continued. T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/8000; March 14th, 1/4000; April 8th, 1/2000; June 4th, 1/1000; June 25th, 1/1000; July 13th, 1/1000; August 2nd, 1/1000; and August 23rd, 1/1000; making a total of eight injections. March 18th: The infiltration was now not so great as before and the nodules were fewer. Sept. 21st: The affection was now very much better; the infiltration was less pronounced, and there were only a few nodules.

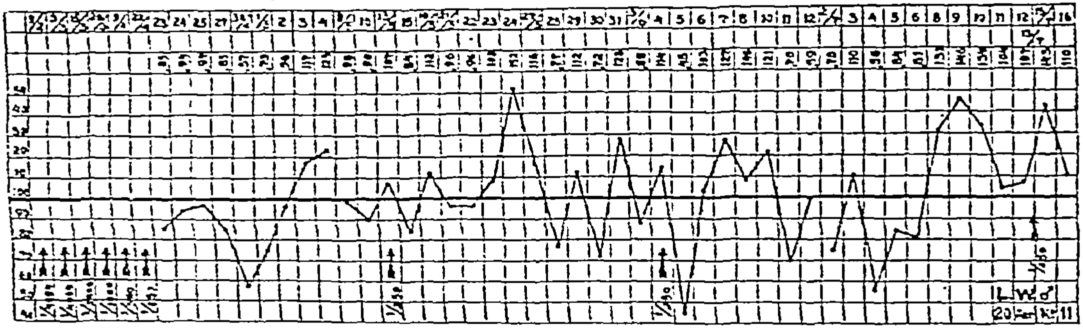
CASE 13.—A. G. (Curve 6). The patient was an unmarried woman, 23 years old, who had been suffering from lupus vulgaris for six months; she had never been treated before. Admitted to Finsen Medical Light Institute on Jan. 21st, 1907. The soft tissues of the nose were red and swollen. On the right side there was an ulcer 2 centimetres in diameter; on the left side there was a series of small ulcers extending down on the septum and the upper lip, where there was an ulcer of the size of a pea. In the cavity of the nose there were extensive ulcers. Light treatment: From Jan. 21st to July 2nd she had 104 sittings; and from August 28th to Sept. 20th she had 24 sittings. The cavity of the nose was treated with the galvano-cautery. On March 3rd the infiltration was very much diminished and the ulcers were healed. In the cavity of the nose there were extensive ulcers. Light treatment was continued. T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; March 14th, 1/2000; April 8th, 1/1000; May 13th, 1/500; June 4th, 1/500; and June 25th, 1/500; making a total of six injections. May 14th: There were now only a few typical nodules. In the left side of the cavity of the nose ulcers still existed. On June 25th there were a few cicatrices but no typical nodules. On August 28th there was some slight desquamation, but there were no typical nodules. In the left side of the cavity of the nose there was an insignificant ulcer.

CASE 14.—K. J. (Curve 9). The patient was a girl, 17 years old, who had been suffering from lupus vulgaris for five years. Admitted into the Finsen Medical Light Institute on Feb. 20th, 1907. There was nothing abnormal on the skin. In the cavity of the nose there were ulcers on the vestibulum and on the mucous membrane. On the prolabium of the upper lip there was a large ulcer which extended into the gum and into the anterior part of the hard palate. On the soft palate there was a small ulcer. On the posterior wall of the pharynx there was a small ulcer. In the larynx there was a defect of the border of the epiglottis with a few small nodules. There were redness and swelling of the introitus laryngis and there was a prominent granuloma in the inter-arytenoid region. The left vocal cord was ulcerated throughout nearly its whole length. There were no other tuberculous affections and in particular the lungs were normal; the urine was normal. Light treatment of the vestibulum nasi, the lip, and the palate. From March 13th to July 20th the patient had 113 sittings. The larynx was treated with lactic acid. The other mucous membranes were treated with the galvano-cautery. At the same time T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; March 14th, 1/2000; April 8th, 1/1000; May 13th, 1/500; June 4th, 1/500; June 25th, 1/500; and July 13th, 1/500, making a total of seven injections. July 20th: The cavity of the nose was now healed. On the upper lip there was an ulcer extending into the gum. The palate was nearly healed. In the larynx the ulcers were healed. The patient went away for a month. On Sept. 4th in the cavity of the nose there was an insignificant ulcer on the septum. On the upper lip there was a rather big ulcer in the middle which extended into the gum and a little down on the hard palate. In the larynx there was some swelling of the mucous membrane. There were no ulcers. The lungs were normal. The urine was normal.

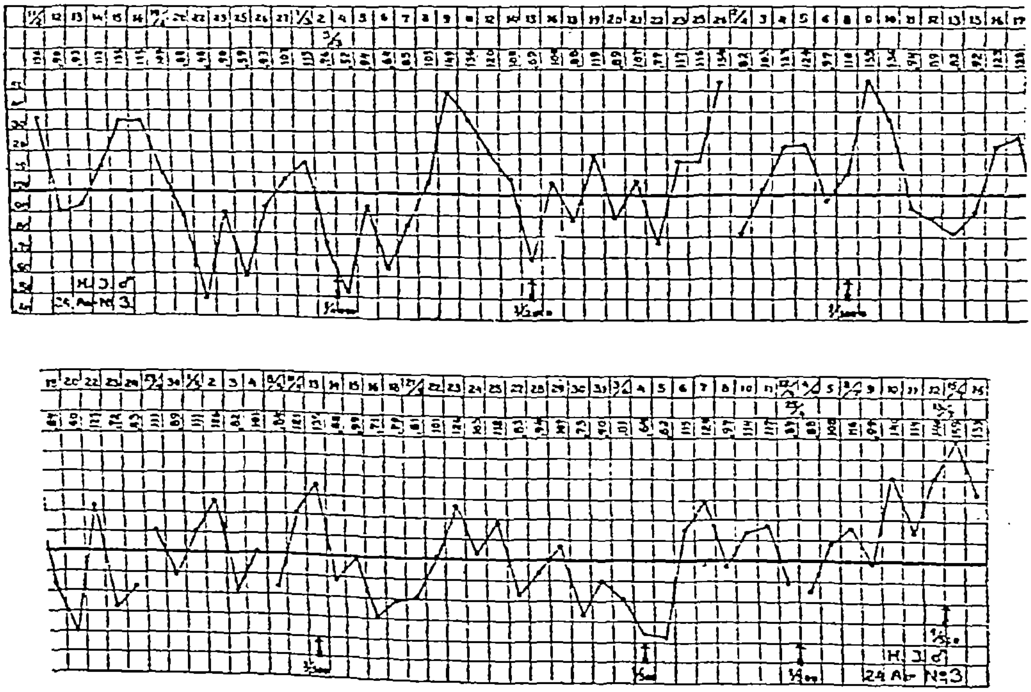
CASE 15.—S. S. (Curve 7). The patient was a married man, 49 years old, who had been suffering from lupus vulgaris for five years. He had been treated with ointments and the galvano-cautery. Admitted into the Finsen Medical Light Institute on Jan. 21st, 1907. On the left ear, the left cheek, the left side of the scalp, and the left side of the neck there was over an area measuring 18 by 9 centimetres a confluent patch of nodules with rather great infiltration. There were no other tuberculous affections, and in particular the lungs were normal. The urine was normal. Treatment with Roentgen rays. On Feb. 18th the affection was much smoother. Light treatment: From Feb. 15th to June 18th, 1907, the patient had 81 sittings. On March 3rd

June 4th, 1/500; June 25th, 1/500; July 13th, 1/500; August 7th, 1/500; and August 23rd, 1/500; making a total of nine injections. By Sept. 12th the affection had grown much. The nose was red and swollen with many partly ulcerated nodules. Around the fistula there was an ulceration. The left cheek was the seat of confluent nodules in a patch of one centimetre in diameter; at the left corner of the mouth there were about ten nodules. On the neck there was a patch measuring 2 by 3 centimetres with nodules. The nasal cavity remained as on March 3rd.

CURVE RELATING TO CASE 1.



CURVE RELATING TO CASE 2.



CASE 3.—A. N. (Curve 2). The patient was an unmarried woman, 36 years old, who had been suffering from lupus vulgaris for 21 years. She had been treated with excochleation and excision several times, until eight years ago she was admitted to the Finsen Light Institute, where from 1899 to 1906 she was treated with 2494 sittings. The mucous membrane was treated with the galvano-cautery. The disease became much better during the treatment, but many deep nodules remained on both cheeks. On March 3rd, 1907, there was some infiltration of the nose, both the cheeks, and the chin. There were scars with many deep typical nodules. In the cavity of the nose there were extensive ulcers. On the prolabium of the upper lip, on the inside of the lips, and on the palate there were small ulcers. Light treatment was given up. On March 3rd T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; March 14th, 1/2000; April 8th, 1/1000; May 13th, 1/500; June 4th, 1/500; July 3rd, 1/500; July 24th, 1/500; August 8th, 1/500; and August 25th, 1/500; making a total of nine injections. By Sept. 6th the nodules had increased very much in size and numbe[illegible] membrane remained as on March 3rd.

CASE 4.—B. D. (Curve 5). The patient was an unmarried woman, 24 years old, who had been suffering from lupus vulgaris for 11 years. She had been treated with ointments until nine years ago she was admitted into the Finsen Light Institute, where she was treated from 1898 to 1906 with 2384 sittings. The patient was treated especially on the face and on the upper limbs, where the affection became a good deal better, but new eruptions constantly made their appearance. On March 3rd, 1907, there were a great deal of infiltration and many widespread nodules in the face. On the neck, on the limbs, and on the trunk there were many in part very large spots with confluent nodules. There was no pulmonary tuberculosis. The urine was normal. Light treatment was given up. On March 3rd T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows:—March 3rd, 1/4000; March 15th, 1/2000; April 8th, 1/1000; May 13th, 1/500; June 4th, 1/500; June 25th, 1/500; July 13th, 1/500; August 2nd, 1/500; and August 23rd, 1/500; making a total of nine injections. On Sept. 6th there was no change. The lungs were normal, as also was the urine.

CASE 5.—T. P. (Curve 10). The patient was an unmarried woman, 39 years old, who had been suffering from lupus for 27 years. She had been treated in many different ways until nine years ago she was admitted into the Finsen Light Institute, where she was treated from 1893 to 1906 with 793 sittings. During the first years the affection grew better, but for economical reasons the patient did not attend to the treatment as she ought to have done and the affection again grew worse. On Feb. 20th, 1907, there was a deep infiltration of the right ear and surrounding parts, measuring 13 by 11 centimetres, with numerous partly confluent nodules; between these some scars were seen. Both [illegible]ous keratitis. The lungs were normal; the

Dr. Robert [illegible] Library

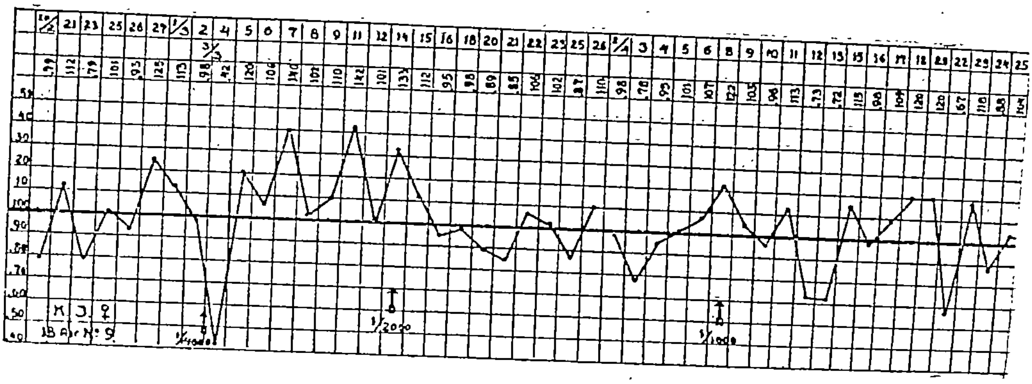
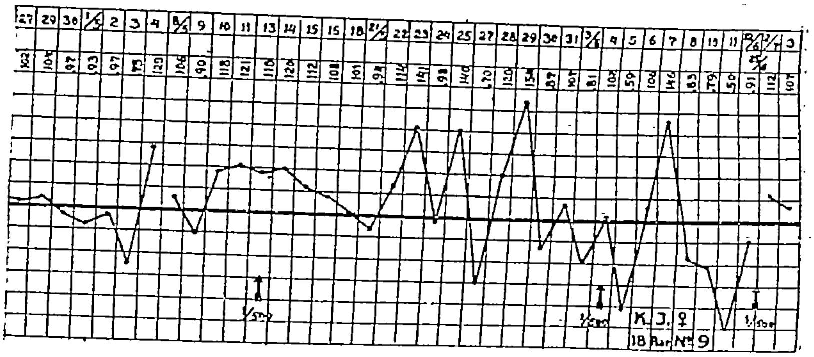
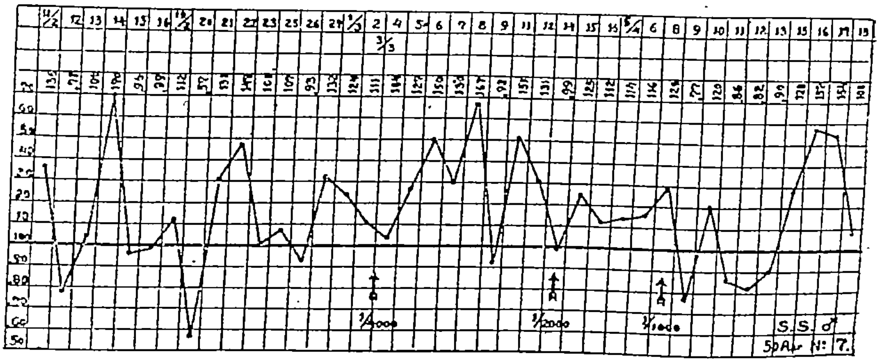
CURVE RELATING TO CASE 14.





CURVE RELATING TO CASE 15.



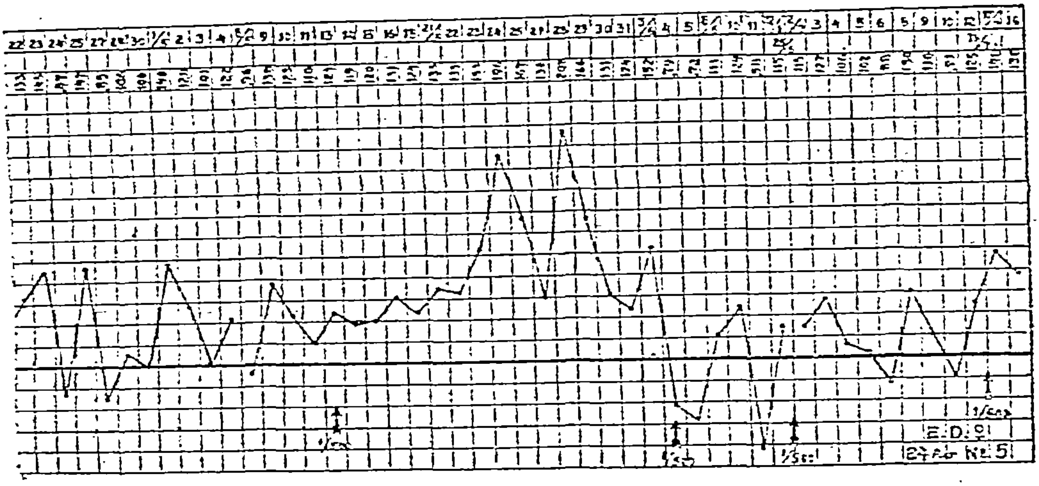
.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 3rd, 1/4000; March 14th, 1/2000; and April 8th, 1/1000; making a total of three injections. On May 27th there was still a rather great infiltration with nodules.

Whether the T.R. has had a good effect on these patients or not we cannot decide because our material is too small. We have not got the impression that their affections have improved more quickly during the combined treatment than would have been the case with light only. Still we wish to go on with these examinations, hoping that a longer series of cases may give a decisive answer on the question. We may safely continue the T.R. injections combined with light treatment because we have never seen any harmful effect on our patients from these low doses of T.R. The temperature which we in the beginning measured very often never showed the slightest rise. The patient's general state of health was never influenced, and we never saw any morbid symptoms referable to the lungs, the intestine, or the kidneys.

THE CUMBERLAND INFIRMARY.—The committee of management of the Cumberland Infirmary has presented to the subscribers its sixty-seventh annual report, being that for the year 1907. The in-patients numbered 1135, 166 over the average of the previous ten years. The out-patients numbered 3214 and the average daily attendance in this department has increased from 48 to 57 persons. The average daily occupation of beds was 93·2 and the average stay of in-patients 30 days. It frequently happened that the wards were overcrowded. During the year 80 patients have received the benefits of the Convalescent Institution at Silloth, assisted by the Agnes Moore fund. The ordinary income for the year amounted to £5149 and the expenditure to £5282. The cost per occupied bed for the year was £52 6*s.* 11½*d.*, which was a reduction of very nearly £3 on the previous year.

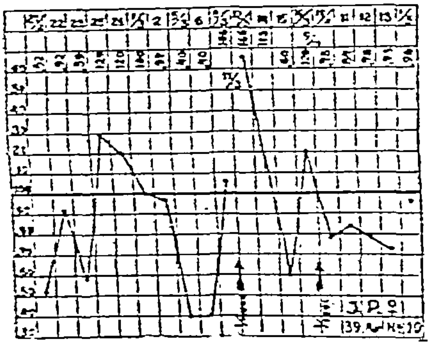
SANATORIUM BUNGALOW BURNT.—Dr. A. H. Wylie, the medical superintendent of the Devon and Cornwall Sanatorium for Consumptives, Didworthy, South Brent, South Devon, has suffered a considerable loss by the rapid burning of his bungalow near the sanatorium which occurred on March 15th, at about 9.30 P.M. Dr. and Mrs. Wylie had retired to rest just previously and the fire was discovered by Miss Wylie and her brother who warned their father and mother in time for them to make their hurried escape. The nearest fire brigade is stationed at South Brent, some distance away, and was not summoned as it was thought it would serve no good purpose. The patients in the sanatorium were unaware of the fire until the following morning. A resolution of sympathy with Dr. Wylie has been passed by the committee of the sanatorium.

CURVE RELATING TO CASE 4—*continued.*



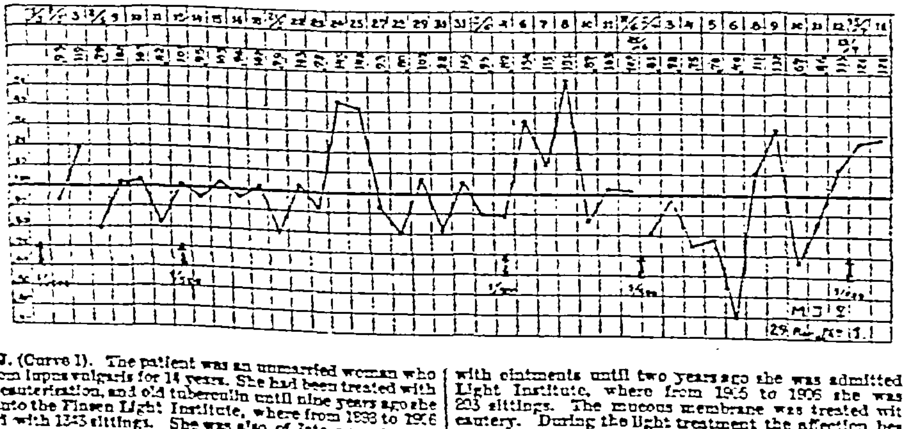
urine was normal. Light treatment was given up. On March 11th T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: March 11th, 1/2000; April 9th, 1/1000; June 4th, 1/500; June 25th, 1/500; July 12th, 1/500; August 2nd, 1/500; and August 23rd, 1/500;

CURVE RELATING TO CASE 5.



making a total of seven injections. On Sept. 14th the affected area was much more infiltrated, with many confluent nodules, some of which were ulcerated. The affection had now spread in the direction of the eye and on the neck. For the rest the extent of the affection remained as on Feb. 20th. The conditions of the eyes had changed at times; at present a serious keratitis again existed. The lungs were normal; the urine was normal.

CURVE RELATING TO CASE 6.



CASE 6.—M. J. (Curve 1). The patient was an unmarried woman who had suffered from lupus vulgaris for 14 years. She had been treated with excochleation, cauterisation, and old tuberculin until nine years ago she was admitted into the Finsen Light Institute, where from 1898 to 1906 she was treated with 1323 sittings. She was also of late years treated with Roentgen rays. The affection got very much better and great parts were healed. On March 15th, 1907, the cheeks were cicatrised without nodules. On the right ala nasi and in the inner corner of the right eye there were small ulcers. There were also nodules on the left upper eyelid, an ulcer on the upper lip near the left angle of the mouth; and widespread nodules and ulcers on the prolabium; on the under lip near the prolabium there were a great many nodules. The chin was without any affection. In the neck there was only a single ulcer one centimetre long. The lungs were normal; the urine was normal. T.R. treatment was commenced. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows:—March 15th, 1/2000; May 13th, 1/500; June 4th, 1/500; June 25th, 1/500; July 13th, 1/500; August 2nd, 1/500; and August 23rd, 1/500; making a total of seven injections. An area of the affection was at the same time treated with Roentgen rays. On Sept. 13th the nodules and ulcers remained on the left upper eyelid, in the inner corner of the right eye, and on the neck, whereas the nose, the upper lip, and the under lip, which had been treated with Roentgen rays, were partly healed up.

CASE 7.—M. H. (no Curve). The patient was a married man, 40 years old, who had been suffering from lupus vulgaris for three years. He had been treated with ointments until he, one and a half years ago, was admitted into the Finsen Light Institute, where he was treated during the years 1905 and 1906 with 239 sittings. The affection grew worse, with a character of pronounced malignity. We therefore at the close of 1906 stopped the light treatment. On Feb. 9th, 1907, there were widespread patches on the left cheek, the neck, the forehead, the left ear, the scalp, the chest, the back, and the right elbow. Most of the glands on the neck were swollen. The lungs seemed normal; the urine was normal. T.R. treatment was begun. The dates of the injections of T.R. and the doses in fractions of a milligramme were as follows: Feb. 9th, 1/4000; and March 3rd, 1/4000; making a total of two injections. April 9th: A couple of days after the last injection the patient was attacked successively with erysipelas, pleurisy, and pneumonia, from which he died. The necropsy showed a widespread tuberculous affection of the glands in the hilus of the lungs. In the lungs there were both old and new tuberculous foci morbus cordis mitralis et tricuspidalis and adherent pericardium were also present. The indices of the patient were not determined.

CASE 8.—J. J. (Curve 8). The patient was a girl, 15 years old, who had been suffering from lupus for five years. She had been treated with ointments until two years ago she was admitted to the Finsen Light Institute, where from 1905 to 1906 she was treated with 203 sittings. The mucous membrane was treated with the galvano-cautery. During the light treatment the affection healed and it was only on the mucous membranes that a relapse occurred Feb. 7th, 1907: On this date there was on the skin nothing distinctly lupous,

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

DERMATOLOGICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on March 19th, Dr. H. RADCLIFFE CROCKER, the President, being in the chair.

Dr. H. G. ADAMSON showed: (1) a case of Urticaria Pigmentosa in a child, aged three years; and (2) a case of Ringworm (tinea circinata) in a child, the ringworm having in all probability been derived from a horse. The father of the patient was a harness repairer.

Dr. T. P. BEDDOES showed for Dr. P. S. ABRAHAM a case of Favus in a Mouse (exhibited). The mouse had been caught by a woman whose husband was attending Dr. Abraham for trichophytic sycosis in which large-spored mycelium had been demonstrated. Dr. Abraham regarded the association in this case of favus with ringworm as fortuitous.

Mr. G. W. DAWSON showed a case of "Ringed Eruption" of the Left Hand and Fingers, of the type of lichen annularis, in a man, aged 18 years, who asseverated that he had had the condition for seven years.—The PRESIDENT considered that it was probably an instance of lichen planus.—Dr. J. GALLOWAY thought that it was rather like what he had called lichen annularis.

Dr. T. COLCOTT FOX showed a case of "Bilateral Telangiectases" of the Trunk in a woman who gave a history of marked epistaxis in childhood and of recent rectal hæmorrhage. There was no family history of similar conditions, which differentiated this case from a group in which these symptoms had been associated with family inheritance. A section of one of the telangiectases showed dilatation of capillaries without other changes.

Dr. WILFRID S. FOX showed a case of Dermatitis Artefacta in a young girl, the lesions consisting of sharply demarcated rounded patches on the chest and left side. The agency of production was not demonstrated.

Dr. GALLOWAY showed a case of an Acute Scarlatiniform Eruption which had apparently resulted from the administration of quinine. The eruption had commenced to show itself within two hours of taking a dose of one grain of quinine and the temperature had risen suddenly to 102° F., with symptoms of shivering, nervous depression, and swelling of the fauces. The rash was followed by widespread superficial desquamation. Similar symptoms had been noted 12 months previously on taking a patent preparation said to contain quinine.

Dr. E. G. GRAHAM LITTLE showed a case of Granulomatous-looking Tumours and Nodules, the result of Ingestion of Bromides, in an infant who had never had that drug but whose mother (who suckled her child) had been daily taking large doses of bromide for two years.

Dr. J. H. SEQUEIRA showed: (1) a case of Lupus of the Face, with a Lymphatic Œdema of the Hands resembling the condition which had been called "Lupus Pernio"; and (2) a case of X Ray Warts which had appeared on the Hands in the course of four years' work of an operator in an x ray department. The warts had been removed from one hand by exposure to measured doses of x rays administered therapeutically.

ODONTOLOGICAL SECTION.

Exhibition of Specimens.—Treatment of Suppurative Periodontitis in Displaced Teeth.—Treatment of Children from the Dental Point of View.

A MEETING of this section was held on March 23rd, Mr. J. HOWARD MUMMERY, the President, being in the chair.

Mr. A. HOPEWELL-SMITH, through the honorary secretary, exhibited and described specimens of (1) Jaws of Hemirhamphus and (2) Developmental Defects in the Upper Jaw of a Pike (*Esox Lucius*), which he presented to the museum.

Mr. E. STURRIDGE read a casual communication on the Treatment of Suppurative Periodontitis in Displaced Teeth, which he contended could not be cured except by the replacement and retention of the teeth in their correct positions. He showed a method of retaining such teeth by means of a wire and small pins cemented to the teeth which had previously had small holes drilled in them. In the discussion which followed it was admitted that the gum did not re-unite with the tooth and that the "pockets" always remained.

Mr. W. HERN opened a discussion on Mr. J. F. Colyer's paper on the Treatment of Children from the Dental Point of View. He opposed Mr. Colyer's views and said he believed that caries occurred in inverse ratio to the amount of care exercised in cleansing the teeth with brush and silk, and that the use of the brush was more important than thorough mastication for preserving the teeth. He was always anxious not to extract the deciduous teeth.—Mr. C. ROBBINS advocated and practised the habit of rewarding his small patients with sweetmeats.—Mr. W. RUSHTON still advocated the use of a toothbrush but did not believe that caries occurred in inverse proportion to its use. He agreed with Mr. Colyer that they did not know the causes of dental caries at all thoroughly.—Dr. J. SIM WALLACE asked why, if the toothbrush was efficient, there had not in recent years been a great decrease in the amount of dental caries, and contended that it was quite possible to bring up children immune from caries who had never used a toothbrush, and instanced cases under his care. He believed that thorough mastication was most important and blamed "pap" feeding for the craving for sweets, the lack of proper mastication, and a great deal of caries. Mouth-breathing was another cause.—Mr. STANLEY P. MUMMERY thought that the interference of civilisation with the laws of survival of the fittest was a cause of the prevalence of caries.—Mr. COLYER, in reply, said he was satisfied to have proved by the discussion which he had provoked that there was a wide difference of opinion among dental surgeons as to the causes of caries. It was a fact that the chemical composition of modern food-stuffs had changed. He did not think that heredity was an etiological factor and he strongly believed that dental surgeons would be able by discovering the causes of dental caries to remove them, and that in the future a healthy and functional mouth would be far more common than at the present day.

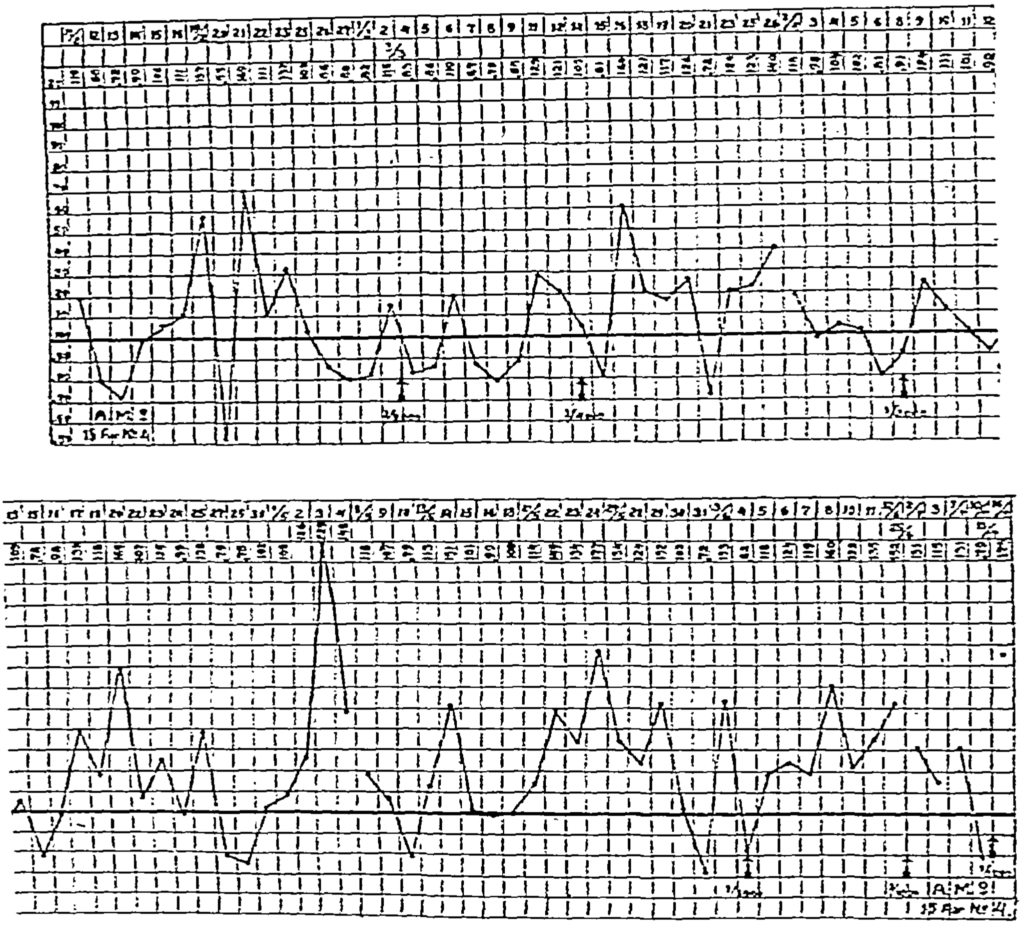
THE MEDICO-LEGAL SOCIETY OF LONDON.

Discussion on Post-mortem Examinations in Cases of Death under Anæsthetics.—The Legal Liability of the Anæsthetist.

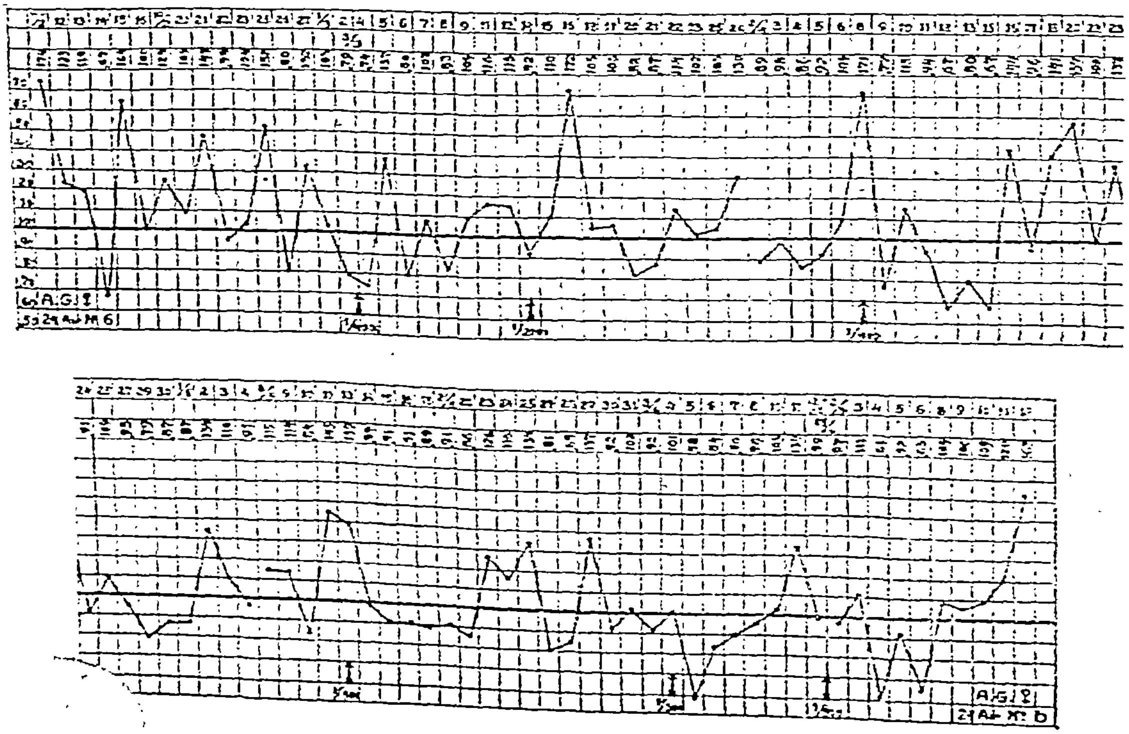
CONSIDERABLE interest was manifested in a meeting of this society held on March 24th, when Mr. Justice WALTON, the President, occupied the chair.

The discussion on Dr. L. Freyberger's paper read at the last meeting, entitled "An Analysis of 74 Cases of Sudden Death while under the Influence of Anæsthetics," had been adjourned and the proceedings were commenced by Mr. R. HENSLOWE WELLINGTON who read a short paper on the Legal Liability of the Anæsthetist, in the course of which he said: Dr. Freyberger read his paper on "Deaths under Anæsthetics" before this society on Feb. 11th, 1908. That paper was limited to a narration of 74 cases upon which he had made post-mortem examinations for the purpose of inquests in the Westminster and South-Western jurisdiction of the coroner. Out of the 74 deaths, 71 occurred at the five large hospitals and three in private practice. Though Dr. Freyberger gave an interesting narrative of these cases he drew no deductions from them. But during the short discussion which followed Dr. Frederic W. Hewitt gave us to understand that the majority of deaths from or under an anæsthetic were preventable, and that if death took place it was, as a rule, not the patient nor the operator that was at fault but the anæsthetist. I take it, then, that in his opinion the patient dies from an overdose of the anæsthetic—*i.e.*, that he or she is poisoned owing to a want of care on the part of the anæsthetist. That we all value Dr. Hewitt's opinion goes without saying, but it must first be proved that these deaths are due to the anæsthetic itself, and secondly to the want of reasonable skill, care, and attention on the part of the anæsthetist and not due to any contributory cause on the part of the patient from an idiosyncrasy, or to his pathological condition at the time of the operation, or on the part of the operating surgeon, and how can one differentiate between these, or say that there is not a combination of them as causes contributing to the death and so exonerate everyone concerned? It would be well for the Privy Council, with whom this matter rests, to make it a penal offence for an unqualified

CURVE RELATING TO CASE 12.



CURVE RELATING TO CASE 13.



required a course of instruction and four did not. In Scotland there were six examining bodies but only one required a course, and in Ireland there were five, none of which required it. That was not a satisfactory state of things and something was required to remedy it. Then what was the state of things at the hospitals? There was some improvement in this direction but at a certain number of them there might be a rather better system, both of instruction to students and of administering the department responsible for the use of anæsthetics. He thought that there ought to be some men of the highest professional and academical attainments at the head of the teaching portion of this study, and that especially there was room for resident anæsthetists at many of the large hospitals. The result of this unsatisfactory state of things was shown by the annual returns of the Registrar-General and by the weekly records of cases of death under anæsthetics. He was not contending that deaths could be avoided. He was not dealing in any way with the question of specialism; he was dealing merely with the average medical man, and he maintained that the average medical man passed from his hospital without having the proper equipment in this department of practice in the public interest. Statistics must be looked upon as absolutely valueless. Who could say what particular share the anæsthetic, the operation, or the pathological condition of the patient had in causing the death? A committee of the British Medical Association sat some years ago upon the subject and all its labours were practically thrown away. Nothing came from that most carefully conducted clinical inquiry simply because it knew in discussing any given case that there was this difficulty. The two proposals which he submitted would, he personally believed, have the effect of very materially lessening the evil with which they were confronted. The Society of Anæsthetists had, he believed, approached the General Medical Council and had been told that there was no room for another subject, but he thought that it must appeal to everyone who recognised the importance of the subject that some alteration was necessary. He congratulated the society in occupying the happy position of being of great use not only to the public but to the medical profession in general, which by reason of being split up into a great number of bodies was not able to act as could a single society of this character.

Mr. HENSLOWE WELLINGTON seconded the motions.

Sir ALFRED FRIPP said that the question was an extremely complicated one because there were many different points of view from which it might be approached. Dr. Hewitt's proposal that every student should have a course of instruction had, of course, won hearty support. The second motion should have the support of the medical profession, but if such a law was passed that none but qualified men should administer anæsthetics, it would be hitting a large number of the public who got their tooth extracted and a whiff of gas for the modest half-crown. They would be driven into the hospitals and dispensaries and the large body of the medical profession who made their money by small driblets would suffer. Speaking as coming from a hospital with a large dental department he thought that they would find themselves overburdened with work. It opened up the possibility of having to face a very large social question of whether there was not already more than enough done for that very large class that could afford something but could not afford to pay the full fee for medical or surgical attendance and who were very prone to get their services for nothing at all. As regards operations in the country very difficult circumstances were found and where it was not always possible to procure the services of a special anæsthetist. Whether this should be met by the creation, or rather the multiplication, of the special class of anæsthetists, or whether it would be better met, as Dr. Hewitt had suggested, by the leavening up of the whole profession by requiring students to take a course in anæsthetics, as was done at many hospitals, was worthy of consideration. He was surprised to find that the responsibility of the administration of anæsthetics was upon the surgeon. He had certainly thought that the surgeon who availed himself of the assistance of the skilled anæsthetist shifted the responsibility. If the surgeon dared to interfere no anæsthetist would brook that interference for a moment. In his hospital they took proper care that every student should have attended a course in the administration of anæsthetics and should have seen them administered and have taken part under the skilled anæsthetist attached to the hospital. He believed that such a course tended to the turning out of a class of men much more likely to be able to avoid those common mistakes of the past.

Dr. R. J. PROBYN-WILLIAMS regretted that the discussion was confined to the two motions, which would receive the hearty approval of anæsthetists present. He thought that Dr. Hewitt was rather extreme when he said that he wished for more teaching in anæsthetics and at the same time said that the drugs were safe. If he had been fortunate enough not to see a patient die on the operating-table it was exceptional. There were many cases at any rate in which the patient was in the absolute extremity of danger and nothing but the greatest skill had saved his life. It was a good deal owing to the efforts of the Society of Anæsthetists that at any rate the Royal College of Surgeons of England had made this important branch of practical science a part of its curriculum.

Dr. F. J. SMITH referred to Dr. Hewitt's statement (made at the February meeting of the society) that nine out of ten deaths under anæsthesia could be avoided by greater care upon the part of anæsthetist and said that it surely went beyond the limits of fair criticism of the whole body of skilled anæsthetists. He thought that motion No. 2 contained a pious opinion which he was afraid would go the way which good intentions were said to go. He could not imagine the legislature passing anything like an Act based on those lines, or interfering with quackery, of which perhaps nineteen-twentieths of the members availed themselves. There must be hundreds of operations performed by the medical man which the student had never seen performed. He contended that if a man did his level best he was not responsible for any particular catastrophe. He asked the coroners present if they honestly thought that any 12 jurymen they called together were fit judges to decide the question as to who was responsible for the death? What would be the effect of the motion upon some unfortunate practitioner who met with a catastrophe when one of the jury asked what steps he had taken to resuscitate life and who on receiving the answer which he would not understand would say that he was going to stick out for a verdict of manslaughter. He protested against coroners holding inquiries in these cases. He was heartily with Dr. Hewitt in wishing that the students should be educated, but it must be remembered that whilst in London there was nothing easier than to get a skilled anæsthetist it was very different with a man say in Wiltshire. A degree of skill would be expected from Dr. Hewitt which would not be expected from a practitioner in the country.

Professor J. GLAISTER (Glasgow) considered that the present state of the law was anomalous. It was news to him that herbalists and bone-setters gave chloroform; he never heard of it in Scotland. It had been his misfortune to have to make inquiries into deaths under anæsthetics in every hospital, small and large, in and around Glasgow and some in private cases. He was inclined to think that chloroform was one of the most uncertain drugs in its operations because the factor that was not constant was the person to whom it was being administered. Dr. Hewitt must consider the living factor a little more. Each man in the hospital schools in Glasgow received tuition in the administration of anæsthetics. Dr. Hewitt would find himself on dangerous ground in stating that nine out of ten of the cases of death could be avoided by attention on the part of anæsthetists. In hospitals men of the highest rank as anæsthetists had deaths. There was surely a share in the condition of the patient which must be considered. There were two classes of operation—the operation of necessity and the operation of expediency. Surgeons had not infrequently to operate to give a patient a chance of life when he would not be justified in withholding that chance. He did not think the profession should advertise itself as incompetent to do its work. The second motion, he agreed, was but a pious opinion; he quite supported the first but unfortunately everybody was crying for lengthening the medical curriculum and if they were medical students they would think it long enough already.

Dr. F. J. WALDO said that from an examination of the machinery whereby the facts relating to investigated deaths were recorded he was led to believe that the data were worthless as to the ratio of deaths to the administration of anæsthetics. He referred to his article on this subject that had already appeared in THE LANCET.[1]

Dr. C. TEMPLEMAN (Dundee) said that at St. Andrews University no student was allowed to graduate without

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF PERFORATIVE APPENDICITIS IN A PREGNANT WOMAN, FOLLOWED BY ABSCESS OF THE THYROID GLAND AND ABORTION.

BY H. S. PENDLEBURY, M.A., M.B. CANTAB., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, ST. GEORGE'S HOSPITAL; SURGEON TO THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.

THE patient, a woman, aged 27 years, who was about four months pregnant and whose thyroid gland had always been large, was admitted into St. George's Hospital on March 31st, 1907. She had been seized with acute abdominal pain on the previous day with vomiting.

On admission the patient was a thin, anxious-looking woman. Her temperature was 100° F., the pulse was 120, and the respirations were 36. There were great pain and tenderness in the right iliac fossa. The abdomen was distended but not very rigid. A vaginal examination showed fulness in the right fornix and fluctuation could be obtained bimanually. The condition was diagnosed as acute perforative appendicitis with abscess. On March 31st an operation was performed. The incision was carried through the right rectus muscle. An abscess was found in the pelvis, of which the cæcum and appendix formed the superior boundary. The appendix was removed and the abscess was drained with gauze and a tube. The pathological report was acute gangrenous, perforative appendicitis. Recovery of the abdominal condition was uneventful. The wound was healed and the patient was convalescent on April 14th.

On April 21st the patient had a rigor with a temperature of 101°. On the 25th she complained of stiffness of the neck and of her throat feeling sore. On the 27th swelling of the enlarged thyroid was noticed, with some hoarseness. On the 30th this swelling had increased very rapidly during the previous 48 hours and there were considerable tenderness and some dyspnœa. An operation was performed under chloroform and ether. An incision was made in the mid-line over the most prominent part of the swelling. About a couple of ounces of pus with pieces of gangrenous thyroid came away. The pus had the characteristic foul odour of bacillus coli communis infection. A tube was introduced. The bacteriological report was as follows: "The pus contains bacilli like the bacillus coli communis, but it is not possible to cultivate these." The abscess healed rapidly.

On May 27th the patient suddenly aborted. Very little blood was lost. Her general condition was good. On June 11th she was removed to the convalescent hospital at Wimbledon and on the 25th she was discharged recovered.

I saw the woman in February last and there was then no evidence of any myxœdematous condition, so that some of her thyroid tissue remains active.

Remarks.—Mr. James Berry[1] remarks that a thyroid gland which is already enlarged is the more likely to be the seat of an abscess. Metastatic abscesses of the thyroid gland apart from enteric fever are sufficiently rare to warrant my publishing this case, and I have been unable to find any record of an abscess in this position caused apparently by the bacillus coli.

Brook-street, W.

NOTE ON TWO CASES OF ANTHRAX UNTREATED.

BY JOHN CROPPER, M.D. CANTAB.

THE recent publication of two cases of anthrax by Dr. J. S. Clarke in THE LANCET of Feb. 29th reminds me that at Nablus, in Palestine, I had lately two cases which were so far untreated that the final result was not affected either way. One case showed very unusual symptoms. This patient, a youth, aged 19 years, whose work was not concerned with wool in any way, was attacked by malignant pustule on the right cheek. When I saw him for the first time on the twelfth day of the illness a large typical "pustule" nearly one and a half inches in diameter, with dark "eschar" surface and surrounded by much induration, was seen on the right malar eminence. For some days he had been absolutely paralysed from below the nipple line on both sides. As a last chance the pustule was freely excised under chloroform, but though cicatrisation set in no recovery from the paralysis ensued and he died about three weeks later. He had before I saw him been treated by a quack with caustics in an ineffectual manner. Only a few very doubtful bacilli could be made out from the discharge. The second patient was a woman, aged 50 years, on the back of whose neck a little above the vertebra prominens an anthrax pustule had developed, which had gone on to a "natural cure" before she came under my observation as an out-patient. By this time she had in the site indicated a deep hole, measuring one inch in diameter and also in depth; it was filled by a white and firmly adherent slough and excreted an abundant discharge, exhaling a most fœtid odour. The skin was crater-like and much undermined. The slough came away in large pieces and she made a perfectly "uneventful recovery" in the course of two or three weeks.

Though comparatively rare, anthrax is more often met with in Palestine than in England. I have seen cases of *charbon des paupières* once or twice; these, by causing sloughing of the upper eyelid, give rise to some of the very worst cases of loss of the eyelid. Shortly before leaving the East I was asked to operate on a man whose eyelid had sloughed, leaving the eyeball exposed through an opening in the same.

Chepstow, Monmouthshire.

NOTE ON A CASE OF POST-INFLUENZAL PERICARDITIS.

BY F. CARMINOW DOBLE, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON, GREAT NORTHERN CENTRAL HOSPITAL.

A MAN, aged 21 years, was seized on March 4th with giddiness, nausea, and aching in his legs; this was followed on the next day by a very slight nocturnal cough and pain over the præcordial area, chiefly limited to the apex beat. The temperature was normal; the pulse was 85 per minute and of good volume and tension. I diagnosed influenza. Examination of the chest revealed nothing abnormal until on March 13th I again examined his chest. Inspection, palpation, and percussion yielded no evidence of disease, but on auscultation over the space between the second and third rib, close to the sternum, a double friction sound was to be heard. It was nearly synchronous with systole and diastole, the heart sounds were partly obscured, but no murmur or reduplication was present. When the patient held his breath the abnormal sounds were not altered. The area over which the friction sounds could be heard was of about the size of half-a-crown. They were very high pitched and sibilant and were greatly increased on pressure on the chest with the stethoscope. On the next day they were not so well marked and the day after that were quite gone. The patient says that he had an attack just like the present one last year and a medical man said "it was influenza affecting the heart."

It is curious that the pericardium should be affected by so mild an attack of influenza, especially with so few bronchial symptoms. It seems to prove that Pfeiffer's bacillus circulates in the blood early in the disease in even a mild form and produces a true septicæmia.

Reedham, R.S.O., Norfolk.

SALARIES OF POOR-LAW MEDICAL OFFICERS.—The Local Government Board has recently informed the Falmouth board of guardians that a payment of £20 per annum was insufficient remuneration for the medical officer of the workhouse. At a meeting of the guardians held on March 26th Mr. Preston-Thomas, the Local Government Board inspector, stated that he had been instructed to confer with the guardians on the matter. He added that the salary was about 7*s.* weekly and the medical officer had to supply medicines out of that, so that his remuneration was about the same as would be paid to a boy for scaring crows. Mr. Preston-Thomas contended that it was unreasonable to pay a medical officer such a sum for the duties which he performed. After some discussion the guardians decided to take no action on the suggestion of the Local Government Board.

---

[1] Diseases of the Thyroid Gland, 1901, pp. 130 et seq.

Dr. HEWITT, replying on the second, said that the one object before them all was the safety of their patients. There should be no hair-splitting. When he said that nine cases out of ten were preventable he was speaking of the cases which had been described by Dr. Freyberger and others which clearly indicated that in a large number of cases the patients died from intercurrent asphyxial conditions which might have been avoided. Again, a gentleman who had recently died with an honourable record passed through a life of anæsthetic cases without having ever lost one—he had tens of thousands of cases. He (Dr. Hewitt) contended that the average medical man if properly trained on the principles such as a master of the art would be able to transmit to his students would be able to save life in about the proportion he had indicated. He had never intended to say that chloroform or any drugs could be regarded as safe. By careful treatment it was possible to render them comparatively safe—that was to say, if given in a haphazard way it was a dangerous drug, if given on a proper scientific principle it was not a dangerous drug. Dentists in the country administered gas because there were no properly trained men. The very large number of deaths occurred from asphyxia and unless a man had been highly trained he was not able to watch the respiration and guide it along through its various abnormal phases in such a way as thoroughly to protect the life of the patient.

Dr. FREYBERGER having briefly spoken the second proposition was put to the meeting and carried.

LIVERPOOL MEDICAL INSTITUTION.

Reminiscences of 42 Years' Professional Life in Liverpool.

A MEETING of this society was held on March 19th, Mr. T. H. BICKERTON, the President, being in the chair.

Dr. W. CARTER gave an address on Reminiscences of 42 Years' Professional Life in Liverpool. He remarked that owing to recent reviews of the advances in medicine and surgery by Dr. A. T. H. Waters and Professor W. Rushton Parker during a period almost contemporaneous with the time of his residence in Liverpool, he would confine himself to a statement of some of those public controversies and events in which he had taken part. The first, and perhaps the most trying, was the Contagious Diseases Acts. Believing that these degraded both the womanhood and the manhood of the country he was obliged to oppose them. In conjunction with the late Dr. Nevins, Dr. Ewing Whittle, and others they established a national association for their repeal in March, 1875, at a meeting at St. George's Hall, Liverpool, and decided to start a journal, the *Medical Enquirer*. He was honorary secretary to the association and sole editor of the journal, also a purely honorary position. The work lasted until the repeal of the Acts in 1886, Dr. Nevins distinguishing himself above all others by his zeal and work. The next public controversy was that concerning the position of the public abattoirs and hide market in a densely populated part of the city and very near to the Royal Infirmary. On behalf of a deputation from the Medical Institution he presented in 1884 to a meeting presided over by the then mayor statistical tables proving the greater unhealthiness of the district than of any other district generally similar anywhere in Liverpool. This was confirmed by a subsequent report made by Dr. Stopford Taylor, the then medical officer of health, and later still, in February, 1903, he was requested by the committee of the Royal Infirmary to meet the estate committee and to endeavour to dissuade it from renewing the lease of the abattoir. With the late Sir William Banks and Mr. Robert Gladstone he strongly urged this course on the authorities and trusted that this evil would ere long be removed. Dr. Carter next spoke of his prolonged efforts in the promotion of total abstinence both in Liverpool and elsewhere. Another controversy which was maintained for many years was that concerning the notification of infectious diseases without the slightest discretion being allowed in any case. He presided over a large meeting of the medical profession in that theatre in September, 1882, on the subject. After prolonged discussion and numerous meetings a compromise was agreed upon and the form now employed was sanctioned. The attempt to persuade the late Sir William Jenner to found a medical defence union, its subsequent formation, and later still the presidency by the late Mr. Lawson Tait, with Dr. Carter as a vice-president, were mentioned and everyone present was urged to join the present ably conducted union. In 1870–71 the visitation of Liverpool by a severe outbreak of small-pox was the occasion of Dr. Carter's writing a series of articles in the *Medical Times and Gazette*, after examination of all the returns supplied by the parish medical officer in charge of the public sheds. The mortality was strikingly inverse to the number and size of the cicatrices. Many years later, therefore, when the practice had arisen of some medical men making one small pin-prick and terming that efficient vaccination he felt bound to bring the matter before the Lancashire and Cheshire branch of the British Medical Association on Feb. 28th, 1889, at which a resolution adverse to this was come to at a large meeting. On March 23rd, 1904, at a large public meeting held at the Philharmonic Hall, under the presidency of Mr. Emmott, M.P., the Protestant Bishop of Liverpool proposed, and Dr. Carter seconded, motions which had the effect of starting the Congo Reform Association. As chairman of the professional subcommittee of the Tropical Diseases School since its formation, he felt much embarrassment at times owing to his having to protest against the extravagant laudation in the annual reports of the school of King Leopold of Belgium, and when invited to accompany the president of the school and some of his colleagues to Brussels to luncheon with the King last August twelve months he was obliged to refuse the invitation. When the midwives registration controversy arose he felt bound, under the conviction that many humble homes were wrecked through the spread of puerperal fever owing to uneducated and ignorant women, strongly to support the Bill for the education and registration of midwives. The matter was very hotly discussed on May 11th, 1894, at a large meeting held in that room, when his motion on the subject was lost by a large majority. He published his speech, copies of which were requested by the Royal College of Physicians of London for its library table, and finally, as everyone now knew, an Act was passed in 1902 compelling the education, certification, and supervision of all women practising as midwives. Dr. Carter lastly drew attention to the generosity and public spirit of the wealthy men of Liverpool, especially mentioning Mr. Sutton Timmis who after the death of his wife communicated to Dr. Carter through his friend Mr. Wade Deacon his desire to place £10,000 in the hands of trustees for promoting a cancer research, over the committee for carrying out which he (Dr. Carter) had presided, and still continued to preside, as chairman. He mentioned other splendid acts of generosity on the part of the same gentleman, and finally spoke of the extraordinary response to the appeal made by himself a few years ago for the family of the hero Mr. William Smyth, Liverpool contributing hundreds of pounds. Rich and poor alike gave, one poor man sending 2*d*. and another 6*d*., while a poor dressmaker begged to be allowed to make clothes for the children and was overjoyed when allowed to do so; but no class contributed so generously or so generally as the medical profession who alone could estimate the great risks and the noble way in which that heroic man, like a true soldier, had met them.

A hearty vote of thanks, proposed by Dr. W. MACFIE CAMPBELL and seconded by Professor W. RUSHTON PARKER, was accorded to Dr. Carter for his excellent address.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 17th, Mr. H. Shackleton, the President, being in the chair.—Dr. F. W. Eurich read a paper on Tuberculosis of the Lung, in which he said that recovery was often spontaneous and that to obtain a cure nature's own methods must be employed. The outcome of this was the modern sanatorium treatment. Since the treatment had been restricted to suitable *early* cases the results had considerably improved. Experience seemed to show that the cases suitable for sanatorium treatment were those (1) with simple catarrh at one apex; (2) infiltration or consolidation at one apex, with or without catarrhal symptoms; and (3) infiltration with consolidation of *one* upper lobe. The other lung should not be appreciably affected. Contra-indications seem to be: (1) cavity formation; (2) repeated severe hæmorrhages; (3) persistent elevation of temperature; (4) albuminuria or glycosuria; and (5) severe tuberculous affections of other organs. But what about the cases whose disease had died down in spite of the fact that their lives had been spent in the slums under conditions in which every law of health was violated? The only explanation was that the man to administer any anæsthetic, whether local or general. Perhaps the coroner's court is not the *fons et origo* of exact scientific knowledge upon the matter of the immediate scientific cause of death in these cases, though it must be admitted that the court certainly has a useful function to perform in the matter and should ascertain if there has been any *malpraxis*. But I am struck with the idea that a most useful office might well be created by the county councils if they would appoint some one with a medical training and a coroner's experience to act as a registrar, such as the hospitals possess, to make an abstract or digest from the depositions, taken at inquests by the coroners, upon these and all other deaths. These depositions are at present a mass of wasted material, but would be a source of much useful information if in the hands of such an officer or registrar. It has been argued by some (though n[illegible] at this society) that if the anæsthetic were not required then the anæsthetist is liable at law. Surely if an operation is necessary an anæsthetic is, humanely speaking, equally so. It is then the operating surgeon who is to be called into question if anyone for *malpraxis*, but who can controvert his opinion as to whether the operation was necessary or not? If the anæsthetist is an unqualified practitioner and is engaged by the qualified operator, or if an unqualified operator engages a qualified anæsthetist, then the qualified and registered man, surgeon, or dentist is guilty of "covering," under the regulations of the General Medical Council, whether the patient lives through or dies under the anæsthetic. And here I will say *en passant* that it is very doubtful as to whether the dentist who has the L.D.S., without the full qualification of the physician or surgeon, is qualified to give any anæsthetic at all, or whether he is not limited to the administration of nitrous oxide gas and must call in a qualified practitioner to give the other anæsthetics; he is then in the same position as the unqualified man. If the anæsthetist is engaged by a *surgeon to* adminster the anæsthetic, the surgeon is the servant of the patient and agent to find a capable anæsthetist, and if both show reasonable care, skill, and attention neither of them is liable for *malpraxis* whether the patient lives or dies. Again, if the operating surgeon engages an anæsthetist who gives an anæsthetic for an illegal operation, the anæsthetist if ignorant of the illegality of the operation cannot be held liable whether the patient survives or dies, but if the anæsthetist knows the nature of the operation to be *illegal* he is equally liable to answer with the surgeon for felony if she survives and for murder if she dies. If the *causâ causans* of the death is due to a pathological condition of the patient, unknown until the patient is upon the operating-table, the death must of necessity be one of misadventure, or if due to a recognised pathological condition and the patient or his representative had been warned *of* any risk and accepted that risk the patient then accepted full responsibility and exonerated both the surgeon and the anæsthetist. Supposing that the anæsthetist sees danger from the anæsthetic after he has commenced its administration and withholds his hand, at the same *time warning* the operating surgeon that to proceed is dangerous, the *onus probandi* is perhaps thrown upon the surgeon if he proceeds with the operation, though it may be well-nigh impossible to finish it forthwith. But naturally the two must work together and do their best for the life that is in their hands and then no one can reasonably find fault or sustain any action at law for *malpraxis*. When a patient enters any hospital and an operation under an anæsthetic is required the patient expects, and the law implies, that a competent anæsthetist will give the necessary anæsthetic, and if a qualified practitioner administers it and uses reasonable care and skill he cannot be held liable for *malpraxis* if unforeseen death supervenes. Further, if an unqualified man, as pupil, is manipulating the anæsthetic apparatus under the supervision of a qualified anæsthetist the former is not acting illegally, nor is the latter liable for "covering," as this is permissible under the regulations of the General Medical Council. But there is often the risk that the young anæsthetist is hurried in his work by the busy hospital surgeon who is anxious to hurry on the operation and get away to his private practice, consequently the anæsthetist runs the risk of administering a poisonous dose of the anæsthetic. This is an argument in favour of special resident anæsthetists at all our large hospitals. In conclusion, the immediate cause of death attributable to the anæsthetic, *per se*, as a poison, must first be proved beyond any reasonable doubt; and then a further proof that the administrator of that anæsthetic or poison—and it matters not whether he be a qualified or an unqualified practitioner—did not use reasonable care, skill, and attention must be shown before he can be made answerable to the law for damages or punishment. But the administration of any anæsthetic, whether for a local or a general anæsthesia, by unqualified practitioners—which is carried on to a very large extent throughout the kingdom—is a grave public danger and should, perhaps, be made a penal offence by statute.

The PRESIDENT then suggested that Dr. F. W. Hewitt should propose the motions standing in his name. The question before the meeting was not primarily the medical or the scientific side of the matter but rather the question of public policy. Of course, it would be important to have the opinion of gentlemen who spoke not only with great scientific knowledge but with practical experience.

Dr. HEWITT then moved that the two following motions be forwarded in the name of the Medico Legal Society to the General Medical Council and to the Privy Council respectively:—

1. That in view of the importance of the administration of anæsthetics this society is of opinion that it is highly desirable, in the public interest, that every member of the medical profession before he is registered shall have received instruction in the administration of anæsthetics. It therefore earnestly begs the General Medical Council to consider whether they can see their way to include a course of instruction in anæsthetics amongst their requirements in regard to professional education.

2. That as the administration of any drug or drugs with the object of producing generalised insensibility to pain or actual unconsciousness for any medical and surgical operation, or during child-birth, cannot be safely undertaken without medical knowledge and skill, your petitioners humbly pray that legislation be granted whereby the administration of any drug or drugs with either of the aforesaid objects by any person other than a duly registered medical practitioner or some one acting immediately under his supervision, direction, and instruction be made a penal offence.

One question seemed to Dr. Hewitt to come to the front before all others on that occasion—namely, the means which should be adopted for protecting the public against accidents under general anæsthetics. It was one of the most vital and pressing questions of the day. The present state of things he could only describe as antiquated and slipshod. In the first place what was the present position of the law? He felt that he was treading on most delicate ground because he was not a lawyer. It appeared that any person, whether qualified or unqualified, experienced or inexperienced, reputable or disreputable, might administer an anæsthetic, and provided that he did this to the best of his ability and with no unlawful motive he was not likely to be punished or even blamed if his patient died as the result of the anæsthetic given. Was it right in the public interest that some of the most powerful drugs in the British Pharmacopœia should be at the disposal of ignorant, if well-intentioned, persons? The community was protected against risks incidental to the sale of poisons, the adulteration of food, milk, and the like, but the advertising bone-setter, the herbalist, or in fact anyone might freely employ chloroform without any infringement of the law. When anæsthetics were first introduced, more than half a century ago, they were often intrusted to unqualified persons, nurses, and others; but surgery had completely changed since then and the requirements of the surgeon and of the public were such that the administration of an anæsthetic, in the modern sense of the term, could only be safely undertaken by those possessing medical knowledge and skill. Possibly the attractions of medicine and surgery had taken away men of brilliant abilities whose work would have been welcomed by those who had interested themselves in this particular branch, but at the present time the average medical man who gave an anæsthetic and the general practitioner in the country had not had the amount of training which he ought to have had and that amount of experience which would entitle him to administer these drugs. Secondly, he would refer to the share which the educational authorities took in the matter. The General Medical Council, which governed the various examining bodies, did not make a course of instruction in anæsthetics one of its requirements. It recognised that some instruction should be given. He had written recently to the 22 examining bodies of England, Scotland, and Ireland and he found that only eight made it compulsory for candidates to have received any instruction in anæsthetics. So that a man might graduate in medicine and surgery at one of our leading Universities without ever having administered an anæsthetic. In England there were 11 examining bodies; of these seven showed the skiagram.—*Dr. Solly* showed a case of a child who had an Eruption on the Face and Limbs probably due to scabies.—Mr. J. D. Harmer showed for Mr. A. C. Roper a case of extensive Epithelioma of the Skin of the Face.—Mr. Harmer also showed a case where Mr. Roper had performed the Radical Mastoid Operation.—Mr. Domville showed a case of Middle-ear Disease in a man where he had performed the radical mastoid operation, and had also opened an abscess in the temporo-sphenoidal lobe, and another case in a girl where the radical mastoid operation had been performed. Both patients were doing well.—Mr. Harmer showed for Mr. Roper the Suprarenal Capsules removed post mortem from a case of Addison's disease exhibiting extensive caseation. Mr. Harmer also showed for Mr. Roper a Meckel's Diverticulum removed during operation for supposed appendicitis.—Dr. Solly showed Blood Films of: (1) Benign Tertian Malarial Parasite from a patient recently in the Royal Devon and Exeter Hospital; and (2) Myelocytic Leukæmia in the case of a man exhibited showing neutrophile, eosinophile, and basophile myelocytes, and nucleated red corpuscles. Dr. Solly also exhibited the test for Acetone, lately described in THE LANCET, where equal quantities of the urine and a weak solution of nitroprusside of sodium are mixed together in a test tube and strong ammonia (0·880) is floated on the top. A prune-coloured ring was demonstrated where the fluids joined.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 12th, Dr. G. Thomson, the President, being in the chair.—Professor J. M. Beattie read a paper on Acute Rheumatism: the Evidence in Support of its Bacterial Origin. After reference had been made to the clinical resemblances between acute rheumatism and other infective diseases and the epidemic nature of the disease a brief outline was given of the work of the various observers who had isolated organisms from cases of acute rheumatism. The work of Wassermann was specially emphasised and the confirmation of this work by Poynton and Paine, Ainley Walker and Beaton, Fitzmeyer, and others was reviewed. Professor Beattie then gave an outline of his own work in which, with a streptococcus isolated from three typical cases of acute rheumatism, he had produced in rabbits the clinical picture of acute rheumatism. He laid special stress on the fact that the organism in his cases was localised to certain areas in the synovial membrane and was not found in the blood or joint exudations. By intravenous injection he produced in a series of 23 rabbits 76 per cent. of non-purulent arthritis and 56 per cent. of endocarditis. Only three animals of the series died, two of these with very acute arthritis, and one with large mitral vegetations. In two of these the streptococcus was found in the blood but in the other it was found only in the synovial membrane of the knee-joints. These results were compared with parallel experiments carried out by himself and by Rufus Cole with streptococci from other sources than rheumatism and it was shown that the conditions produced were quite dissimilar, the arthritis being purulent and the endocarditis uncommon. Recovery was rare, the death-rate being 40 per cent. in his own cases and 80 per cent. in those of Cole. Reference was also made to the occurrence of acute interstitial nephritis in the animals experimented upon and of amyloid degeneration in cases of rheumatic fever. From the experimental work it was concluded that in acute rheumatism, at any rate in adults, the bacteria are in the majority of cases localised and that many of the clinical manifestations and pathological effects are due to the toxins.

NURSING AND MIDWIFERY CONFERENCE AND EXHIBITION.—In order to arouse and to maintain interest in the provision of properly trained midwives it is proposed to hold a series of annual conferences at which lectures will be given and discussions held on subjects of importance to midwives and new appliances shown. The first conference has been arranged to take place from April 28th to May 1st prox., under the patronage of H.R.H. Princess Christian, and it will be held at the Cavendish Rooms, Mortimer-street, Regent-street, London, W. It is hoped that railways will grant special rates to those attending the congress. No subscriptions are asked and there are to be no entrance charges. Tickets will be distributed from provincial centres or will be forwarded to responsible nurses and midwives who apply, sending a stamped addressed envelope, to Mr. Ernest Schofield, organising secretary, 32, Sackville-street, Piccadilly, London, W.

Reviews and Notices of Books,

A System of Medicine by Eminent Authorities in Great Britain, the United States, and the Continent. Edited by WILLIAM OSLER, M.D. Oxon. and McGill, F.R.S., Regius Professor of Medicine in the University of Oxford, England; formerly Professor of Medicine in Johns Hopkins University, Baltimore, &c. Assisted by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. III.: Infectious Diseases (continued); Diseases of the Respiratory Tract. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 960. Price to subscribers, 24*s.*; to non-subscribers, 30*s.*

IN our review of the first volume of this "System"[1] we explained the nature and scope of the work and expressed the opinion that it would be sure to secure the favour of a large public. As will be seen by the title detailed above, the present volume completes the consideration of the infectious diseases and also contains a series of articles on diseases of the respiratory tract.

The first contribution is on Malta Fever and is written by Colonel David Bruce, R.A.M.C. He defines the fever as a disease of long duration, characterised clinically by continued fever, profuse perspiration, constipation, frequent relapses, rheumatic or neuralgic pains, swelling of joints or orchitis; bacteriologically by the presence in the blood and organs of the micrococcus Melitensis (Bruce); and anatomically by congestion of the spleen and other organs. He also shows that the disease is a widespread one, cases having been reported from numerous places in the Mediterranean and also in Hong-Kong, in the Philippine and Fiji Islands, in the Mississippi Valley, and in certain places in the West Indies and in South America. The cases, however, do not seem to occur in large numbers in any place except Malta. The manner in which the micrococcus may enter the body is discussed at length and infection by means of goat's milk is duly referred to. The evidence in favour of this mode of infection is very strong and many of the curious features in the epidemiology of Malta fever are thus explained. The treatment of the disease has not as yet made any great advance. Hydrotherapy is probably the most useful measure, baths or sponging being employed.

Beri-beri is described by Dr. Maximilian Herzog. He remarks that in spite of the fact that the pathological anatomy of this disease is well known the etiology is far from being definitely and satisfactorily understood. The various theories which have been advanced as to the cause of the malady are discussed, especial attention being drawn to the observations of the two Japanese army surgeons, Okata and Kokubo, who had an excellent opportunity of studying the large number of cases transferred from Manchuria to Japan during the recent Russo-Japanese war. These investigators isolated a coccus which generally assumes the form of a diplococcus and which may also at times present itself as a coccus. They confidently maintain that this coccus is the causal factor in beri-beri. Dr. Herzog, however, is by no means convinced on the point. He failed to obtain the same organism from typical cases of beri-beri in the Philippine Islands. Also in about 50 cases of the disease occurring in Manila the search for the coccus again proved negative. He seems to have no doubt that in spite of these failures beri-beri is an infectious malady and is of opinion that further bacteriological investigations are necessary.

In Chapter III. Dr. Mazÿck P. Ravenel gives a good account of the present state of knowledge in reference to Anthrax, Rabies, and Glanders. The subject of Tetanus is discussed by Dr. J. M. Anders, and that of Leprosy by Dr.

---

[1] THE LANCET, Oct. 19th, 1907, p. 1091.

man to administer any anæsthetic, whether local or general. Perhaps the coroner's court is not the *fons et origo* of exact scientific knowledge upon the matter of the immediate scientific cause of death in these cases, though it must be admitted that the court certainly has a useful function to perform in the matter and should ascertain if there has been any *malpraxis*. But I am struck with the idea that a most useful office might well be created by the county councils if they would appoint some one with a medical training and a coroner's experience to act as a registrar, such as the hospitals possess, to make an abstract or digest from the depositions, taken at inquests by the coroners, upon these and all other deaths. These depositions are at present a mass of wasted material, but would be a source of much useful information if in the hands of such an officer or registrar. It has been argued by some (though not at this society) that if the anæsthetic were not required then the anæsthetist is liable at law. Surely if an operation is necessary an anæsthetic is, humanely speaking, equally so. It is then the operating surgeon who is to be called into question if anyone for *malpraxis*, but who can controvert his opinion as to whether the operation was necessary or not? If the anæsthetist is an unqualified practitioner and is engaged by the qualified operator, or if an unqualified operator engages a qualified anæsthetist, then the qualified and registered man, surgeon, or dentist is guilty of "covering," under the regulations of the General Medical Council, whether the patient lives through or dies under the anæsthetic. And here I will say *en passant* that it is very doubtful as to whether the dentist who has the L.D.S., without the full qualification of the physician or surgeon, is qualified to give any anæsthetic at all, or whether he is not limited to the administration of nitrous oxide gas and must call in a qualified practitioner to give the other anæsthetics; he is then in the same position as the unqualified man. If the anæsthetist is engaged by a surgeon to administer the anæsthetic, the surgeon is the servant of the patient and agent to find a capable anæsthetist, and if both show reasonable care, skill, and attention neither of them is liable for *malpraxis* whether the patient lives or dies. Again, if the operating surgeon engages an anæsthetist who gives an anæsthetic for an illegal operation, the anæsthetist if ignorant of the illegality of the operation cannot be held liable whether the patient survives or dies, but if the anæsthetist knows the nature of the operation to be illegal he is equally liable to answer with the surgeon for felony if she survives and for murder if she dies. If the *causâ causans* of the death is due to a pathological condition of the patient, unknown until the patient is upon the operating-table, the death must of necessity be one of misadventure, or if due to a recognised pathological condition and the patient or his representative had been warned of any risk and accepted that risk the patient then accepted full responsibility and exonerated both the surgeon and the anæsthetist. Supposing that the anæsthetist sees danger from the anæsthetic after he has commenced its administration and withholds his hand, at the same time warning the operating surgeon that to proceed is dangerous, the *onus probandi* is perhaps thrown upon the surgeon if he proceeds with the operation, though it may be well-nigh impossible to finish it forthwith. But naturally the two must work together and do their best for the life that is in their hands and then no one can reasonably find fault or sustain any action at law for *malpraxis*. When a patient enters any hospital and an operation under an anæsthetic is required the patient expects, and the law implies, that a competent anæsthetist will give the necessary anæsthetic, and if a qualified practitioner administers it and uses reasonable care and skill he cannot be held liable for *malpraxis* if unforeseen death supervenes. Further, if an unqualified man, as pupil, is manipulating the anæsthetic apparatus under the supervision of a qualified anæsthetist the former is not acting illegally, nor is the latter liable for "covering," as this is permissible under the regulations of the General Medical Council. But there is often the risk that the young anæsthetist is hurried in his work by the busy hospital surgeon who is anxious to hurry on the operation and get away to his private practice, consequently the anæsthetist runs the risk of administering a poisonous dose of the anæsthetic. This is an argument in favour of special resident anæsthetists at all our large hospitals. In conclusion, the immediate cause of death attributable to the anæsthetic, *per se*, as a poison, must first be proved beyond any reasonable doubt; and then a further proof that the administrator of that anæsthetic or poison—and it matters not whether he be a qualified or an unqualified practitioner—did not use reasonable care, skill, and attention must be shown before he can be made answerable to the law for damages or punishment. But the administration of any anæsthetic, whether for a local or a general anæsthesia, by unqualified practitioners—which is carried on to a very large extent throughout the kingdom—is a grave public danger and should, perhaps, be made a penal offence by statute.

The PRESIDENT then suggested that Dr. F. W. Hewitt should propose the motions standing in his name. The question before the meeting was not primarily the medical or the scientific side of the matter but rather the question of public policy. Of course, it would be important to have the opinion of gentlemen who spoke not only with great scientific knowledge but with practical experience.

Dr. HEWITT then moved that the two following motions be forwarded in the name of the Medico Legal Society to the General Medical Council and to the Privy Council respectively:—

> 1. That in view of the importance of the administration of anæsthetics this society is of opinion that it is highly desirable, in the public interest, that every member of the medical profession before he is registered shall have received instruction in the administration of anæsthetics. It therefore earnestly begs the General Medical Council to consider whether they can see their way to include a course of instruction in anæsthetics amongst their requirements in regard to professional education.
>
> 2. That as the administration of any drug or drugs with the object of producing generalised insensibility to pain or actual unconsciousness for any medical and surgical operation, or during child-birth, cannot be safely undertaken without medical knowledge and skill, your petitioners humbly pray that legislation be granted whereby the administration of any drug or drugs with either of the aforesaid objects by any person other than a duly registered medical practitioner or some one acting immediately under his supervision, direction, and instruction be made a penal offence.

One question seemed to Dr. Hewitt to come to the front before all others on that occasion—namely, the means which should be adopted for protecting the public against accidents under general anæsthetics. It was one of the most vital and pressing questions of the day. The present state of things he could only describe as antiquated and slipshod. In the first place what was the present position of the law? He felt that he was treading on most delicate ground because he was not a lawyer. It appeared that any person, whether qualified or unqualified, experienced or inexperienced, reputable or disreputable, might administer an anæsthetic, and provided that he did this to the best of his ability and with no unlawful motive he was not likely to be punished or even blamed if his patient died as the result of the anæsthetic given. Was it right in the public interest that some of the most powerful drugs in the British Pharmacopœia should be at the disposal of ignorant, if well-intentioned, persons? The community was protected against risks incidental to the sale of poisons, the adulteration of food, milk, and the like, but the advertising bone-setter, the herbalist, or in fact anyone might freely employ chloroform without any infringement of the law. When anæsthetics were first introduced, more than half a century ago, they were often intrusted to unqualified persons, nurses, and others; but surgery had completely changed since then and the requirements of the surgeon and of the public were such that the administration of an anæsthetic, in the modern sense of the term, could only be safely undertaken by those possessing medical knowledge and skill. Possibly the attractions of medicine and surgery had taken away men of brilliant abilities whose work would have been welcomed by those who had interested themselves in this particular branch, but at the present time the average medical man who gave an anæsthetic and the general practitioner in the country had not had the amount of training which he ought to have had and that amount of experience which would entitle him to administer these drugs. Secondly, he would refer to the share which the educational authorities took in the matter. The General Medical Council, which governed the various examining bodies, did not make a course of instruction in anæsthetics one of its requirements. It recognised that some instruction should be given. He had written recently to the 22 examining bodies of England, Scotland, and Ireland and he found that only eight made it compulsory for candidates to have received any instruction in anæsthetics. So that a man might graduate in medicine and surgery at one of our leading Universities without ever having administered an anæsthetic. In England there were 11 examining bodies; of these seven whilst the pathologist Hanau considered it to have its origin in the periosteum. Dr. Denker points out that, although the view put forward by Katz is at least a probable one in many cases, yet the fact that the mucous membrane appears to be normal in so many instances must, if this theory be accepted, leave unexplained a certain proportion of the cases, and we must of necessity be forced to consider that a primary affection of the periosteum or the bone must account for these, though we are not as yet in a position to state whereabouts it commences. This is rendered the more probable when we consider that Politzer has demonstrated the existence of isolated foci of disease unconnected with the surface and the periosteum.

Dr. Denker next reviews the etiology of the affection. Here he points out that in the larger proportion of cases the disease appears in the female sex, and he alludes to the opinion of Walb that it is due to the condition of the blood in pronounced anæmia which is so much more often found in women than in men, and that pregnancy also has an influence on the development of the disease. He also refers to the well-established facts pointing to the influence of heredity. We find, however, that in the larger number of Dr. Denker's patients—namely, in no less than 77·7 per cent., the disease commenced between the ages of 20 and 50 years. 26 out of the 306 cases were affected in the second decade and 34 (or 11·1 per cent.) after the fiftieth year, while eight patients could give no history. Chill is credited with a large share in the causation of otosclerosis, while by other writers something more than a casual relationship is ascribed to syphilis. Beyond these three factors no other cause—casual or otherwise—is adduced. Under the heading of functional testing we find, carefully described in historical precedence, all the various aural tests and their explanations, so far as our present knowledge goes. In the symptomatology and progress of the disease the author refers, amongst other things, to the temporary character of the disturbances of equilibrium as well as to their relative rarity in otosclerosis, as compared with diseases of the middle ear proper. He enters fully into the various theories extant as to the causation of paracusis Willisii and gives preference to that which assumes that people speak more loudly in a noise. A very useful and short summary of the diagnosis is given. The most important portion of the book, however, is a careful and elaborate description of the pathological, macroscopical and microscopical, conditions found in all the hitherto reported cases. This is by far the most complete summary extant. The concluding chapter of the book deals with what the author very pertinently describes as "various therapeutic experiments."

We have dwelt at unusual length on the contents of this work, for we feel that it would not have been possible otherwise to do justice to the result of the important labours of the author. That the last word has not yet been spoken on this subject there is no question. But to all those who are interested in the advancement of otology, whether it be from a scientific standpoint or from the desire to be able to afford relief to the numerous sufferers from this insidious complaint, Dr. Denker's book will prove of the utmost value.

The Elements of the Science of Nutrition. By GRAHAM LUSK, Ph.D., M.A. Illustrated. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 326 Price 12s. net.

IT is a far cry to the time of Sanctorius of Venice in the early part of the seventeenth century. He, however, was the first to apply the balance, or rather a steel yard, to the study of the "insensible perspiration." The modern science of nutrition began with Lavoisier who with Laplace made experiments on animal heat and respiration. Lavoisier declared that life processes are the result of oxidations with the resulting formation of heat. Liebig received part of his training in Paris in 1822. His researches in Munich and elsewhere fired Voit to study the problems of metabolism. With the name of Voit must be associated that of Pettenkofer who made famous the Munich School of Metabolism. The work has been carried forward with extraordinary success by Rubner, a former pupil of Voit. Lavoisier established the fundamental fact that the oxygen inspired and the carbon dioxide given off depend primarily on food, work, and temperature. Liebig devised new methods for organic analysis and the study of the carbon compounds. With the fact established that the nitrogen in the urine and the fæces could be made a means for the determination of protein metabolism the next step was gained. Meat contains 16 per cent. of nitrogen or 1 gramme of nitrogen in 6·25 grammes of proteid, therefore for every gramme of nitrogen in the excreta 6·25 grammes of protein were destroyed in the body. The next question was the determination of the total carbon excreted, which problem was attacked by Voit and Pettenkofer. As to the manner of metabolism, it was shown that the metabolism in the body is not proportional to the combustibility of foodstuffs outside the body, for in the body protein is burned with greater ease than are carbohydrates, while fat is the most difficult of all. It is the metabolic action of the cells which determines the amount of oxygen absorbed. It is not due to a lack of oxygen that sugar does not burn in diabetes, or cystin in cystinuria. The cleavage of these substances into bodies which can unite with oxygen cannot be effected and hence they cannot burn. Respiration does not regulate metabolism, it is metabolism which determines respiration partly by its production of carbon dioxide. Metabolism may be defined as the chemical changes of living cells: "it vivifies the material under the influence of energy potential and chemical compounds."

After an introductory chapter the author sets forth his subject under the following heads: Fæces, Starvation, Temperature, Influence of Protein Food, Specific Dynamic Actions of Foodstuffs, the Influence of Fat, Carbohydrates and Mechanical Work, Normal Diet and Food Requirements during Growth, Metabolism in Anæmia, High Altitudes, Myxœdema, Exophthalmic Goitre, Diabetes, Phosphorus Poisoning, Fever, Gout, and Purin Bodies, and concludes with a study of the theories of metabolism.

Normal fæces are not, as is often stated, composed chiefly of residues of undigested food; they consist chiefly of unabsorbed residues of intestinal secretions. In herbivora, however, they consist largely of undigested or indigestible food, and indeed there is as much nitrogen in the fæces of the cow as in the urine. In connexion with diabetes it is interesting to note that β oxybutyric acid and acetone are present in large amount in extreme hunger. The blood in starvation retains its normal composition as regards its nutrient constituents except that it carries fat in increased quantity to the cells. The plasma is very like normal plasma except that there is a slight increase of globulin. The temperature of a fasting man is usually normal and falls only a few days before death. The regulation of temperature is essentially controlled through the nerves. If a rabbit be cooled to the temperature of 19° C. the heart beat may fall to one beat per minute. The "law of superficial area," known as "Rubner's Law," is not often mentioned in English works. It states that the metabolism is proportional to the superficial area of the animal—*i.e.*, it depends on the amount of heat lost at the surface—and its variation in accordance with this law is necessary for the maintenance of a constant temperature.

There is a careful review of the question as to the origin of fat from proteins. This does take place, probably through an intermediate sugar. As to exercise, we find the having had several opportunities under skilled supervision of the administration of chloroform, but they were not required to show a certificate on coming up for examination. All cases of death under anæsthetics in Scotland were inquired into by the Procurator Fiscal in precisely the same way as were other cases of sudden death, with the addition that the Crown required that the whole of the precognitions with the report should be submitted to some qualified man who was asked to report (1) whether the operation ought to have required the administration of an anæsthetic; (2) whether the patient had been previously examined to see if there was anything to contra-indicate the administration; and (3) whether the anæsthetic had been properly given. All these inquiries were held without the facts coming before the public at all.

Professor H. Harvey Littlejohn (Edinburgh) said that he thought the subject far too wide to lead to any good discussion. There was no advantage in holding a public inquiry. Surgeons must give chloroform for operative purposes and there was no object in setting up the public mind against the use of it and in making people believe that there were greater dangers than was really the case. He went most strongly against Dr. Hewitt if he said there was no danger connected with the administration of anæsthetics. They knew that people died not from chloroform but under chloroform, sometimes during the operation but sometimes from causes apart from chloroform. Then patients came out from chloroform and sometimes died afterwards. What was the proof that death had taken place from chloroform? Could it be obtained from a post-mortem examination? No. He had made many post-mortem examinations and found nothing diagnostic. Could they get proof from a chemical examination? Certainly not. What did the inquest lead to? How were they going to prove any fault either on the part of the surgeon or the administrator so long as he could say he used ordinary precautions? There was no object in having a public inquiry. The only object was to make out what was the cause of death, though he thought there ought to be a post-mortem examination to try to find out what was the cause of death in circumstances entailing the proper scientific examination of the organs. If competent men did that after a time there might be material to lead to an understanding of the state which led to a predisposition in some people, because no doubt there was a predisposition to suffer from the effect of chloroform in individuals.

Dr. J. Blumfeld referred to Dr. Hewitt's statement that nine out of ten deaths were preventable. If deaths were inevitable then those who performed the largest number of operations should have the largest number of deaths, but the reverse was the case. A year's cases were reported in the newspapers numbering 74, and out of these five happened in the hands of men who were constantly engaged in giving anæsthetics and the other 69 in the hands of men with whom it was only an occasional duty. It did not seem to him to be a fair argument that because they did not believe Parliament would ever be induced to legislate on the lines suggested the society should not endeavour to introduce the thin end of the wedge, even if there was no immediate result.

Dr. J. F. W. Silk wished to dissociate himself from the old-fashioned idea that to say that some cases were inevitable was incorrect. He believed that there were cases in which it was perfectly impossible to avoid death. He believed that things had very much improved and although it might be that the licensing bodies did not require any particular form of definite instruction, in most medical schools, at any rate, training was given. He entered a most emphatic protest against the statement that inquests should be held in all cases. One of the favouring factors in causing these deaths was the state of terror which was often induced in a patient by reading sensational literature on the subject. They could not muzzle the press but he would muzzle the coroners.

Dr. W. H. Willcox thought that post-mortem examinations were of great value in many cases.

Mr. Harvey Murphy, barrister-at-law, thought that so long as a qualified man was doing his best the law was perfectly clear but what was wanted in the interest of the law and the public was to prevent unqualified men from dealing with dangerous drugs.

Mr. W. Schröder said that the coroner had no power to hold a private inquiry. He had a discretion in certain cases but that did not apply to any deaths occurring from unnatural causes. It was clearly laid down in the Coroners Act of 1887 that he should inquire in all cases due to violence and where he has reason to believe that the death was unnatural. He held that death from anæsthesia was unnatural and as the law stood an inquest should be held in every case.

Mr. H. Bellamy Gardner thought that they were 50 years behind the time. Chloroform was used everywhere and surely death from it was as natural as any form of death. It could not be differentiated from death arising from the injection of antitoxin to save a patient from diphtheria. He had been an anæsthetist for 13 years and stood in constant terror of being dragged before the coroner and his reputation and living taken away from him in consequence. He had given chloroform in over 20,000 cases and he could not conceive of anything more terrible than having to go before a jury who knew nothing about the subject. The simplest thing would be for the coroner to accept the certificate of two medical men which should be taken in cases of deaths while under anæsthetics as sufficient.

Mr. Hubert Sweeney, barrister-at-law, thought that statistics were of value, for otherwise the present discussion would not be taking place. He thought that even when the medical man did his best he should not be entirely exonerated from responsibility. He might use a drug about which he knew nothing and with regard to which he had not taken the precaution to be properly qualified. If death occurred surely some responsibility attached to him for neglecting to bring himself up to date in his profession. As regarding the suspicion which resulted from inquiries, suspicion would be ten thousand times greater if there were no coroner's inquests as advocated by some of the speakers.

The President said that he quite agreed with the last speaker, and if a person killed a man in performing some operation on him it would not be an absolutely sufficient excuse for that person to say that he had done his best. With regard to the subject of inquests, although that was a little outside the special matter which they were considering, it was impossible to confine the discussion to the resolutions altogether because, after all, it was a discussion on Dr. Freyberger's paper. The law was perfectly simple and plain. The difficulty arose from the facts. The law said that a coroner must hold an inquest if he thought the death was an unnatural one. The coroner was the judge, and if he had reason to think it an unnatural death he must hold an inquest. That involved various questions. To apply it to the death from anæsthetics, in the first place there must be reason to think that the death was caused by chloroform; that was the kind of death they were considering. And then he had to consider whether death by chloroform administered as an anæsthetic in the ordinary course of medical or surgical practice was such a death as an unnatural death. That question might perhaps be considered by the court some day and therefore he (the President) was not going to deal with it now. If death by chloroform was an unnatural death, and therefore if the coroner had reason to think the death was a death by chloroform, he must open an inquest. It seemed to him (the President) to follow that if the death was by an operation, if the man died from an operation, that plainly would be an unnatural death and there would be an inquest in every case in which a man died from an operation. The two things seemed to be on the same footing. With reference to the second of the resolutions, he had not had time to look into the matter carefully, but he thought that undoubtedly the only medical practitioner who committed an offence by practising without a qualification was the apothecary. He thought the Act of George III. was still in force by which persons were forbidden to practise as apothecaries unless they were qualified apothecaries. So far as he knew to practise as a physician, he (the speaker) did not mean to say to pretend he was a physician, but to do the work of a physician or a surgeon was not in itself a penal offence. To practise as an apothecary appeared to be a penal offence. Why, he did not know. But a man might perform operations or administer medicines and so forth provided he did not practise as an apothecary, whatever that meant, without committing an offence in doing so in itself. Of course, if he killed somebody in the course of his practice and he was not qualified he (the speaker) quite agreed that it was not sufficient for him to say he had done his best if he was doing something which was in itself a dangerous thing likely to cause death unless done with great skill and he knew he had no skill. In such a case he thought it would be obviously manslaughter and probably wilful murder.

The first proposition was unanimously agreed to.

nervous system is profusely illustrated and it is refreshing to find that the picture of the spinal cord and nerve roots is true to nature, bringing out the varying sizes of the *different* roots. The diagram of the various conduction tracts given in Fig. 600 is not easy to unravel; it might be improved. The final section illustrates the anatomy of the eye, the ear, the skin, and, in an appendix, the lymphatic system. The last might easily and with advantage be more liberally treated. As with previous sections, a handbook of Essentials is supplied. This is equal in size to this instalment of the Atlas and contains the important details of the subject with due reference to the appropriate plates. Without professing to be unduly exhaustive the letterpress faithfully fulfils the object in view.

Stoichiometry. By SYDNEY YOUNG, D.Sc., F.R.S., Professor of Chemistry in the University of Dublin. With 88 figures in the text. Together with an Introduction to the Study of Physical Chemistry by Sir WILLIAM RAMSAY, K.C.B., F.R.S. London: Longmans, Green, and Co. 1908. Pp. 381. Price 7*s.* 6*d.*—This book forms yet another admirable member of the series of text-books of physical chemistry published under the direction of Sir William Ramsay. In such excellent hands we may expect to find that the subject is brought up to the date of the most recent additions to knowledge and that expectation is fulfilled. Sir William Ramsay says that it is hoped by issuing a series of volumes instead of a single comprehensive treatise to keep abreast of the vast subject of physical chemistry, for as the edition of each volume is exhausted it will be possible for each author to bring his subject up to date. The author of the present volume, Professor Young, has been engaged in considerable research work involving important theoretical considerations and he has brought forward many important experimental facts which strengthen the evidence in favour of given theories. His selection, therefore, as the writer of a text-book on stoichiometry, or the methods used to determine atomic and molecular weights, is justified. The choice has, at any rate, fallen upon an author who has proved in this book that he can write clearly and intelligibly on a difficult subject. Modern students of chemical science are fortunate in being able to obtain a text-book presenting so attractively the latest additions to knowledge (together with historic references as to how such knowledge has been acquired) on the important questions of the determination of atomic and molecular weights.

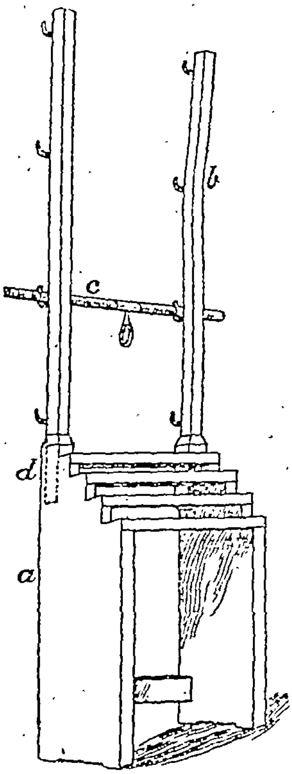
JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM S[illegible] F.R.S., SYDNEY J. HICKSON, F.R.S., and E. [illegible] M.A. With lithographic plates and text fig[illegible]: J. and A. Churchill. March, 1908. New seri[illegible] Vol. LII., Part 2). Price 10*s.*—The articles cont[illegible] this part are: 1. Investigations on the Development of Trypanosomes in the Tsetse Flies and Other Diptera, by E. A. Minchin, professor of protozoology in the University of London (with Plates 8–13 and two text figures). 2. The Nematocysts of Turbellaria, by C. H. Martin, B A., Magdalen College, Oxford (with Plate 14). The presence of nematocysts in turbellaria is, in the author's opinion, due to the transference of the nematocysts of a cœlenterate to the animal which preys upon it. This conclusion is arrived at from the consideration of three facts: (*a*) that the nematocysts of Microstoma lineare are normally derived from the hydra upon which it feeds; (*b*) that if the microstoma is fed upon cordylophora nematocysts are found under the skin; and (*c*) that the nematocysts of Stenostoma Sieboldii are derived from the cœlenterata on which it feeds. The presence, therefore, of three nematocysts in a turbellarian offers no ground for the generally accepted homology between Nematocysts and Rhabdites. 3. Deridoeides Gardineri: A Doridiform Cladohepatic Nudibranch, by Sir Charles Eliot, Vice-Chancellor of the University of Sheffield, and T. J. Evans, lecturer on zoology in the same University; with Plates 15 and 16 and one text figure.

New Inventions.

A NEW APPARATUS FOR WEIGHT EXTENSION.

HAVING recently tried in vain to obtain from instrument makers a simple and at the same time universally applicable device for applying weight extension to fractured limbs I have had made for my own use an apparatus which is shown in the accompanying illustration. It consists of (*a*) a wooden base; (*b*) two wooden uprights carrying a series of hooks in pairs, which support at a convenient height (*c*) a transverse iron bar on which slides a ring carrying a pulley. The special features of the wooden base are that it presents on the side facing the bed a series of steps, on one or other of which the foot of the bed can be supported, thus obviating the use of blocks. Moreover, the apparatus is firmly fixed by the superimposed weight of the bed. The uprights slide into sockets (*d*) at the upper angles of the wooden base and can be removed when the apparatus is not in use, so that the whole can be packed into a space measuring about 4 feet × 2 feet 6 inches × 1 foot. The position of the pulley when the bar is placed on the highest pair of hooks is well adapted for extension with Hodgen's splint. The apparatus can also be used at the side of the bed to apply extension to a fractured arm.



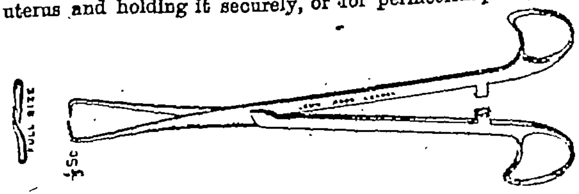
It is quite simple and costs only 23*s.*

H. P. SYMONDS, F.R.C.S. Edin.

Oxford.

A NEW VULSELLUM FORCEPS.

THE annexed illustration represents a new vulsellum forceps which I have devised and for which the following advantages are claimed: 1. The points interlock and therefore cannot give, especially on side pressure. 2. The under surfaces of the points are flattened, which prevents them pulling through the tissues whether it be the cervix when required for such operations as curetting and dilating, or trachelorrhaphy, seizing the fundus of the uterus and holding it securely, or for perineorrhaphies, &c.



3. The upper surfaces of the points are flattened to prevent undue pressure on other tissues. 4. The handles have been so made as to cause as little pressure as possible on the hands. The foregoing points can best be seen from the accompanying diagram.

The forceps have been made for me by Messrs. Down Bros., Limited, 21, St. Thomas's-street, London, S.E., from whom they can be obtained.

J. S. ASHE, L.R.[illegible] S. Irel.

Dublin.

body had been able to raise a sufficient defensive force by the production of antibodies or antitoxins. These substances were produced by the body, where they did not know, in answer to a stimulus applied by the introduction of living germs. Further, the body could be artificially stimulated by the products of the germs in question or by the injection of the dead bacilli themselves. Koch's tuberculins were examples of such excitants, generally known as vaccines. No treatment, therefore, which had not this end in view could be effective. The sanatorium treatment and the vaccine treatment were distinct, but the former could be of no use without the latter, whether produced naturally or artificially. The chief difficulty in both modes of treatment was the dosage. Sanatorium treatment must be long carried out to be effective. Tuberculin if injected in too large a dose paralysed for the time being the production of antibodies. It had been shown by Wright that if a tuberculous knee were exercised or massaged a result was obtained similar to that following the injections of tuberculin. If the exercise had been excessive the production of antibodies sank; if rightly proportioned the formation of antibodies was stimulated. This process he termed auto-inoculation. It followed that the increased amplitude and frequency of the respirations due to walking might be a powerful aid to recovery, or the reverse, in pulmonary tuberculosis. The dose of this exercise must be measured by the opsonic index. At present this could not be applied in practice. Dr. Eurich next discussed the early diagnosis of pulmonary tuberculosis under two heads: 1. Which class of physical signs was the earliest and most reliable? 2. What was the best technique in percussion? He agreed with those authorities who said that the results of percussion were more constant and reliable than those of auscultation. The lightest form of percussion should be practised both in front and at the back and in mapping out an organ the plane of percussion should always be the same. It is by neglecting these precautions that different authors differed so widely in marking out the boundaries of the apex of the lung. The tuberculous nature of the process could be definitely proved in one way only —namely, by the finding of the tubercle bacillus in the sputum, which was a sure sign that destructive processes had already begun in the affected part. If the search for the tubercle bacillus should repeatedly prove negative then there remained four other bacteriological tests for the presence of a tuberculous infection of some organ. The four tests were: (1) the tuberculin reaction; (2) the estimation of the opsonic index; (3) von Picquet's vaccine reaction; and (4) the ophthalmic or conjunctival reaction of Wolf-Eimer and Calmette. Dr. Eurich described and discussed these methods and summed up his conclusions thus: "Given a suspected case of phthisis in which the physical signs are either absent or point only to some catarrh or consolidation at one apex, if tubercle bacilli are not discovered on repeated examination, to clear away any doubt as to the nature of the affection, I would propose to give an injection of tuberculin. If the patient has fever this test cannot be applied. If the eye be healthy I would then apply the ophthalmo-reaction. If the state of the eyes prohibit it and the patient be a child I think I should employ Picquet's test, and failing these I should have the opsonic index taken."—The paper was discussed by Dr. F. W. Goyder, Dr. J. Metcalfe, Dr. Johnston, Dr. H. J. Campbell, Mr. J. Arnold Evans, Dr. G. T. Beatton, and Mr. R. Mercer.—Dr. Eurich then replied.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on March 20th, Dr. O. W. Chapman being in the chair.—Dr. Chapman read a paper on a case of Granular Kidney in a girl, aged 15 years, probably due to congenital syphilis. The patient had always been delicate but it was not until three weeks previously that advice was sought on account of extreme difficulty in breathing and swelling of the feet and legs. The left ventricle was much hypertrophied and the second sound at the base was accentuated; no thrill or murmur could be detected. The radial arteries were hard and thickened. The liver was enlarged nearly to the umbilicus. The urine was of specific gravity 1010 and contained 2½ per cent. of albumin and granular casts. The condition gradually became worse and the patient died seven months later. Post mortem both kidneys were markedly granular, the right weighing two ounces and the left one and a half ounces. Inherited syphilis was suggested as the most probable cause of the condition found in this patient, as the bridge of the nose was depressed and the child's development was that of one six years her junior, and the face had an aged aspect. There was no history of any one of the generally recognised causes of renal inflammation; the mother had had four miscarriages, while of the two children born at term one died at eight months from marasmus.—Dr. F. Langmead showed (1) a case of Mongolian Imbecility associated with other Malformations. The patient was the only child. In addition to the characteristic signs of Mongolian imbecility there were (a) congenital morbus cordis (probably an imperfect septum ventriculorum); and (b) an accessory auricle on the right side. 2. A case of Extensive Anterior Poliomyelitis with Ballooning of the Abdominal Muscles. There were evidences of very extensive involvement of the anterior cornua which had occurred 18 months previously. The legs were useless and allowed great mobility, easily meeting behind the head. The back was sharply curved to the left in the lumbar region. The abdominal muscles were paralysed, especially on the left side, so that on coughing or crying two rounded protrusions were produced due to local yielding of the muscles.—Dr. J. Porter Parkinson showed a case of Tuberculosis of the Kidney with Pyonephrosis. The patient was a girl, aged nine years. During the last 18 months she had suffered from attacks lasting a few days with fever, headache, and pain in the left side of the abdomen. During the last attack a quantity of custard-like material came away with the urine. The liver was not enlarged, but the spleen extended slightly below the costal margin, and immediately below this but more deeply situated was a mass extending downwards for two or three inches, resistant and slightly nodular, with a rounded lower end like a kidney. It was dull except for the colon resonance which could be obtained over it. The right kidney was also thought to be enlarged. Tubercle bacilli had been found in the urine which was reduced in amount, being from 12 to 16 ounces daily. It was acid and deposited a large amount of pus; there was a trace of albumin but no blood. During the last five weeks she had increased five pounds in weight and the pus had almost disappeared from the urine.—Dr. F. Parkes Weber showed a boy, aged 10½ years, suffering from a Chronic Rheumatoid Affection. He also had enlargement of lymphatic glands, ankylosis of both knee-joints, and limitation of movement in the hip-joints.—Mr. Sydney Stephenson showed a case of Juvenile Tabes. The patient, a girl, aged 14 years, had bilateral optic atrophy, imperative desire to urinate, and absence of one knee-jerk and enfeeblement of the other. The family history was suggestive of syphilitic taint, although the patient showed no personal stigmata of inherited syphilis.—Dr. F. W. Higgs and Mr. P. Turner showed a case of Infantile Hemiplegia in a girl, aged eight and three-quarter years. The hemiplegia appeared after a series of fits at the age of ten months. There were lower facial paresis, spastic paralysis of the arm with athetosis of the hand and fingers, and paresis of the leg, with a talipes varus which was only present when the child walked quickly, and was probably of an athetoid nature also.—Dr. George Carpenter showed: 1. A case of Laryngeal Stridor in an infant aged six months. 2. A case of Cerebral Diplegia in a boy aged six years. 3. A Mongol, aged five months, with Congenital Morbus Cordis. 4. Photographs of kidney, ureter, and bladder from a case of Congenital Stricture of the Ureter. 5. Specimens and drawings of a case of Acute Pleuro-Pneumonia, with extensive fibrinous plugs visible to the naked eye in dilated lymphatics.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 12th, Mr. G. L. Thornton, the President, being in the chair.—The following cases and specimens were exhibited. Mr. R. Coombe showed a child the subject of most extensive Nævus of the left side of the face, where very great improvement had taken place under electrolysis, the child having been anæsthetised 11 times.—Dr. R. V. Solly showed a case, under the care of Dr. W. Gordon, of Myelocytic Leukæmia with great enlargement of the spleen in a man, aged about 60 years. There were 850,000 leucocytes per cubic millimetre. The patient was being treated by the x rays and with arsenic.—Dr. Solly showed a case, under the care of Dr. H. Davy, of a man who exhibited some Tabetic Symptoms, having marked Romberg's symptom, loss of knee-jerks, and stamping gait, but no Argyll-Robertson pupil or oculo-motor paralysis or loss of muscular sense. Sight had failed of late and the discs were unduly pale. Shooting pains in the limbs were also present occasionally. The man was a compositor and had suffered from lead poisoning.—Mr. E. J. Domville showed a case of Congenital Dislocation of the Hip in a girl. He also nervous system is profusely illustrated and it is refreshing to find that the picture of the spinal cord and nerve roots is true to nature, bringing out the varying sizes of the different roots. The diagram of the various conduction tracts given in Fig. 600 is not easy to unravel; it might be improved. The final section illustrates the anatomy of the eye, the ear, the skin, and, in an appendix, the lymphatic system. The last might easily and with advantage be more liberally treated. As with previous sections, a handbook of Essentials is supplied. This is equal in size to this instalment of the Atlas and contains the important details of the subject with due reference to the appropriate plates. Without professing to be unduly exhaustive the letterpress faithfully fulfils the object in view.

Stoichiometry. By SYDNEY YOUNG, D.Sc., F.R.S., Professor of Chemistry in the University of Dublin. With 88 figures in the text. Together with an Introduction to the Study of Physical Chemistry by Sir WILLIAM RAMSAY, K.C.B., F.R.S. London: Longmans, Green, and Co. 1908. Pp. 361. Price 7*s.* 6*d.*—This book forms yet another admirable member of the series of text-books of physical chemistry published under the direction of Sir William Ramsay. In such excellent hands we may expect to find that the subject is brought up to the date of the most recent additions to knowledge and that expectation is fulfilled. Sir William Ramsay says that it is hoped by issuing *a series of* volumes instead of a single comprehensive treatise to keep abreast of the vast subject of physical chemistry, for as the edition of each volume is exhausted it will be possible for each author to bring his subject up to date. The author of the present volume, *Professor* Young, has been engaged in considerable research work involving important theoretical considerations and he has brought forward many important experimental facts which strengthen the evidence in favour of given theories. His selection, therefore, as the writer of a text-book on stoichiometry, or the methods used to determine atomic and molecular weights, is justified. The choice has, at any rate, fallen upon an author who has proved in this book that he can write clearly and intelligibly on a difficult subject. Modern students of chemical science are fortunate in being able to obtain a text-book presenting so attractively the latest additions to knowledge (together with historic references as to how such knowledge has been acquired) on the important questions of the determination of atomic and molecular weights.

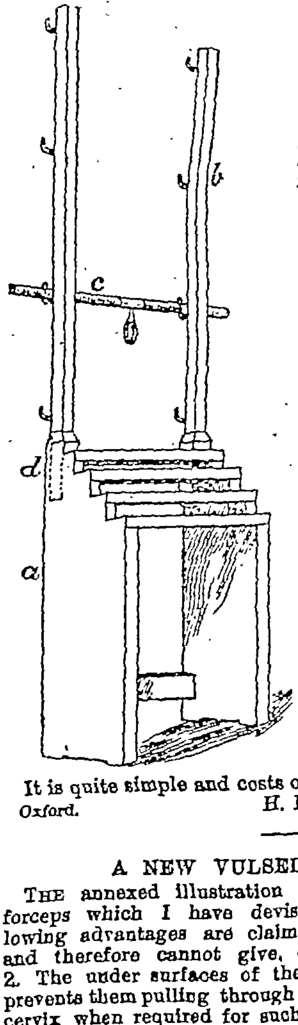
JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM S[illegible], F.R.S., SYDNEY J. HICKSON, F.R.S., and E. [illegible] M.A. With lithographic plates and text fig[illegible]: J. and A. Churchill. March, 1908. New seri[illegible] (Vol. LII., Part 2). Price 10*s.*—The articles cont[illegible] this part are: 1. Investigations on the Development of [illegible]ypanosomes in the Tsetse Flies and Other Diptera, by E. A. Minchin, professor of protozoology in the University of London (with Plates 8–13 and two text figures). 2. The Nematocysts of Turbellaria, by C. H. Martin, B.A., Magdalen College, Oxford (with Plate 14). The presence of nematocysts in turbellaria is, in the author's opinion, due to the transference of the nematocysts of a cœlenterate to the animal which preys upon it. This conclusion is arrived at from the consideration of three facts: (*a*) that the nematocysts of Microstoma lineare are normally derived from the hydra upon which it feeds; (*b*) that if the *microstoma* is fed upon cordylophora nematocysts are found under the skin; and (*c*) that the nematocysts of Stenostoma Sieboldii are derived from the cœlenterata on which it feeds. The presence, therefore, of three nematocysts in a turbellarian offers no ground for the generally accepted homology between Nematocysts and Rhabdites. 3. Doridoeides Gardineri: A Doridiform Cladohepatic Nudibranch, by Sir Charles Eliot, Vice-Chancellor of the University of Sheffield, and T. J. Evans, lecturer on zoology in the same University; with Plates 15 and 16 and one text figure.

New Inventions.

A NEW APPARATUS FOR WEIGHT EXTENSION.

HAVING recently tried in vain to obtain from instrument makers a simple and at the same time universally applicable device for applying weight extension to fractured limbs I have had made for my own use an apparatus which is shown in the accompanying illustration. It consists of (*a*) a wooden base; (*b*) two wooden uprights carrying a series of hooks in pairs, which support at a convenient height (*c*) a transverse iron bar on which slides a ring carrying a pulley. The special features of the wooden base are that it presents on the side facing the bed a series of steps, on one or other of which the foot of the bed can be supported, thus obviating the use of blocks. Moreover, the apparatus is firmly fixed by the superimposed weight of the bed. The uprights slide into sockets (*d*) at the upper angles of the wooden base and can be removed when the apparatus is not in use, so that the whole can be packed into a space measuring about 4 feet × 2 feet 6 inches × 1 foot. The position of the pulley when the bar is placed on the highest pair of hooks is well adapted for extension with Hodgen's splint. The apparatus can also be used at the side of the bed to apply extension to a fractured arm.

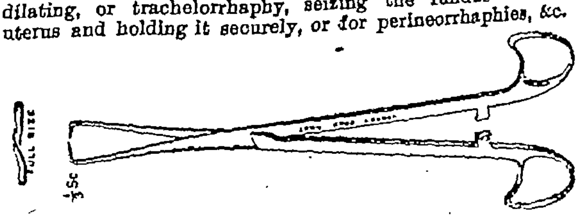


It is quite simple and costs only 23*s.*

Oxford. H. P. SYMONDS, F.R.C.S. Edin.

A NEW VULSELLUM FORCEPS.

THE annexed illustration represents a new vulsellum forceps which I have devised and for which the following advantages are claimed: 1. The points interlock and therefore cannot give, especially on side pressure. 2. The under surfaces of the points are flattened, which prevents them pulling through the tissues whether it be the cervix when required for such operations as curetting and dilating, or trachelorrhaphy, seizing the fundus of the uterus and holding it securely, or for perineorrhaphies, &c. 3. The upper surfaces of the points are flattened to prevent undue pressure on other tissues. 4. The handles have been so made as to cause as little pressure as possible on the hands. The foregoing points can best be seen from the accompanying diagram.



The forceps have been made for me by Messrs. Down Bros., Limited, 21, St. Thomas's-street, London, S.E., from whom they can be obtained.

Dublin. J. S. ASHE, L.R.C.P. & S. Irel.

Isadore Dyer, Tulane University. Chapter V. is devoted to a consideration of Gonococcus Infections, the author being Dr. Rufus J. Cole (Associate in Medicine in the Johns Hopkins Medical School and Hospital).

The subject of Tuberculosis is considered at great length, five chapters being required for the description of the disease in its various aspects. The history and etiology of tuberculosis are discussed by Dr. E. R. Baldwin; the pathology by Dr. W. G. MacCallum; whilst the symptoms, diagnosis, prognosis, prophylaxis, and treatment are described and commented on by Dr. Lawrance Brown. All these authors are American physicians who have had a large experience in tuberculous affections. Dr. Baldwin remarks that one of the most encouraging and instructive facts in connexion with the disease is the remarkable decrease in the death-rate in civilised countries during the last 15 years. He rightly expresses the opinion that this decrease is at once a confirmation of the value of the hygienic measures which have been enforced and one of the obvious benefits of improved conditions of life for the labouring classes in large cities. Some statistics are given in striking proof of these observations. Dr. Baldwin gives an interesting account of the four fairly distinct types of strictly infectious tubercle bacilli which have been recognised—the human, bovine, avian, and reptilian or piscine. He observes that these forms have certain characteristics in common but are sufficiently variable in others to be distinguished from each other. The views held by various observers on the identity or otherwise of these organisms are carefully criticised. The remarks on the mechanism of resistance and immunity afford instructive reading, as do also the observations on the infectivity of tuberculosis. Dr. Baldwin sums up the evidence in connexion with infection in a masterly manner. He considers that the doctrine of inherited or acquired susceptibility still holds sway, except that a specific susceptibility is in doubt and at most is not common; he also maintains that all infants are susceptible, that the susceptibility lessens with increasing age, and further, that adults are comparatively insusceptible "when without general or local lowered resistance and repeated or prolonged exposure." With regard to the sources of infection, he believes that the consensus of opinions and ascertained facts point to the sputum as of overwhelming importance, but in certain cases, and especially in restricted areas in which there is a large percentage of tuberculous cattle, cow's milk is an important factor, the flesh of tuberculous animals being of minor importance. The modes of transmission are also summarised but for a full account of the important matters discussed by Dr. Baldwin we must refer our readers to the original work. The other aspects of tuberculosis are admirably discussed by the physicians whose names we have already mentioned, the remarks on treatment by Dr. Lawrance Brown being particularly worthy of note.

Nine chapters in this volume are devoted to a consideration of the diseases of the respiratory tract. The Mechanism of Respiration and of the Respiratory Tract is ably described by Dr. T. R. Brown, Associate in Medicine in the Johns Hopkins Medical School, Baltimore; Diseases of the Naso-pharynx, Pharynx, and Tonsils, by Dr. F. R. Packard of the Philadelphia Polyclinic; Diseases of the Larynx, by Dr. H. L. Birkett of McGill University; and Hay Fever by Dr. W. P. Dunbar, director of the Hygienic Institute, Hamburg, Germany. Diseases of the Bronchi are discussed by Dr. A. McPhedran of the University of Toronto. He divides cases of bronchitis into two classes: one in which the disease is due to a specific micro-organism, such as the pathogenic organism of influenza, measles, and whooping-cough; and the other he terms "common bronchitis, or bronchitis due to non-specific infections." He considers that "common bronchitis" usually develops from infection by the bacteria normally found in the bronchial mucous membrane or carried down by the inspired air; but the bacteria alone are not sufficient to produce it. Dr. McPhedran therefore maintains that the natural resistance of the mucous membrane must be reduced and this may be brought about by a variety of causes. The bacteria develop, he argues, under the influences of all the causes which lessen the vitality of the epithelium and leucocytes, alter the secretion of mucus and cause congestion of the mucous membrane, whether by disturbance of the vaso-motor function or by enfeeblement of the heart's action.

The chapter on Diseases of the Lungs is written by Dr. Hobart Amory Hare of the Jefferson Medical College, Philadelphia, and his remarks on broncho-pneumonia will be found of value. Dr. Frederick T. Lord of Harvard University is responsible for the chapter on Diseases of the Pleura, Dr. W. B. James (Columbia University) for that on Pneumothorax, and Dr. H. A. Christian (Harvard University) for that on Diseases of the Mediastinum.

The editors of this work may be congratulated on having brought together such a mass of valuable information as is to be found in this volume. Each chapter is practically a monograph on the subject with which it deals and a most valuable work of reference is the result.

Die Ohrenheilkunde der Gegenwart und ihre Grenzgebiete. (Otology of the Present Day and its Province.) In Single Parts. Edited by Dr. OTTO KÖRNER, Honorary Professor of Medicine, Director of the Clinic of the University and of the Polyclinic for Diseases of the Ear and Larynx at Rostock. *Die Otosklerose. (Otosclerosis.)* By Dr. ALFRED DENKER, Extraordinary Professor, Director of the Clinic of the Imperial University and Polyclinic for Diseases of the Ear, Nose, and Larynx at Erlangen. With 11 figures and 8 diagrams. Wiesbaden: J. F. Bergmann; Glasgow: F. Bauermeister. Pp. 135. Price 4s. 9d.

Dr. Denker, in the first chapter of this book on otosclerosis, describes with minuteness the anatomical characteristics and peculiarities of the inner wall of the tympanic cavity and he points out the importance to be attached in this disease to the fact that the cartilage which surrounds the oval window sends processes into the bone itself, and also that there are found at various spots in the labyrinthine capsule small cavities containing remnants of cartilage. He also details with great accuracy the functions of the various bones and muscles in connexion with rarefaction or compression of the atmosphere. The second chapter consists of remarks on the physiology of the ear and Dr. Denker draws attention, amongst other things, to the researches of Helmholtz, who showed how well qualified the auditory apparatus was to receive the deeper tones of the scale by air conduction. He also refers at length to the researches of Bönninghaus on the temporal bone of the whale, which is only connected with the other cranial bones by connective tissue and to the deductions which Bönninghaus made from this fact. Another argument which the author brings forward as a proof of the part played by the auditory ossicles in the perception of sound is derived from the contemporary appearance in the lower animals of the auditory apparatus and of the ossicles.

A short section is devoted by Dr. Denker to a definition of what is understood by otosclerosis and here we may remark that in this work neither chronic sclerosis of the catarrhal type nor that condition left after, or arising from, suppurative otitis is included. The various theories as to the origin of the disease are dealt with—namely, that put forward by Katz, that a predisposing cause in the shape of a constitutional dyscrasia exists, which, however, always requires an acute inflammatory condition of the part to set up the usual chain of pathological changes; and that held by Moos, Bezold, and others, that the process is a primary one in the bone and is not dependent upon previous inflammation of the middle ear;

when they have been due to pressure only. A distinction must be drawn between a total transverse lesion anatomical in nature and one which is merely physiological. Complete physiological abolition of function may occur without actual destruction of the nerve elements and these nerve elements may recover more or less completely. In this connexion the point of the greatest interest is the *question of the possibility* of regeneration of a sutured cord. A peripheral nerve if sutured will unite and in favourable circumstances it may recover completely. Can a similar recovery take place in the spinal cord after complete division and suture? Most observers have agreed that in man such regeneration cannot take place but recently two cases have been reported in each of which the spinal cord had been divided by a bullet and had been sutured. In both a remarkable degree of recovery was reported, so the question has had to be discussed anew. Many experiments have been performed on animals and none of these experiments provides any definite evidence of regeneration of the divided cord, and it is suggested that as the central nerve fibres do not possess a neurilemma sheath from which nerve *regeneration* in peripheral nerves mainly, *if not solely*, occurs this is the reason for the non-regeneration of the cord. A few tracts of fibres of the cord which are of undoubted peripheral type may attempt to regenerate but the attempt appears to be abortive. The clinical evidence is even less convincing than the experimental and at *present it can only be said that* recovery of function after total loss indicates that the *loss of function* must have been due to pressure or œdema or some other removeable cause. On what cases of fracture-dislocation of the spine should the surgeon operate? The main object of an operation in fracture-dislocation is to relieve pressure, whether from bone or from blood clot. If the pressure be allowed to continue a degeneration will assuredly result which will be as *serious as though* the cord had been destroyed by the original injury. It is true that, so far as we know, *no operation* will restore a cord in which *complete* transverse section has taken place; but as we cannot determine in a reasonable time whether a total *transverse lesion* is present or not we should surely, urges Mr. ARMOUR, give the patient the benefit of an operation which experience shows neither materially endangers his life nor *adds* to his discomfort but lessens his pain. The tendency at the present time is to select only the exceptional case for operation. Mr. ARMOUR endorses WALTON when *he says*, Should we not rather *select as* unsuitable for operation the *occasional* case in which definite contra-*indications* for operation exist? In fact, the *rule* should be to operate, the *exception* to refrain from *operation*.

In the last lecture was considered the *surgery of* tumours involving the spinal *cord*. These may be divided into those primarily in the *coverings* of the cord, *only* involving the cord secondarily, *and those* originating from the spinal *cord* itself. Mr. ARMOUR described the various *forms* of growth arising from the vertebral column which may *involve* the spinal cord and also tumours *of the* membranes and *of* the cord itself. He quoted statistics which *show* that extramedullary tumours are over four times as frequent as the intramedullary and of the *extramedullary* the intradural are twice as frequent as the extradural. Of intramedullary tumours it is worthy of note that *tubercle* and gumma have the shortest course, nine months and seven and a half respectively, while sarcoma and glioma have a course of two years or more. In all cases, except those in which the symptoms are due to a syphilitic mass, the only possible treatment which can be of any avail is operation, and its success will depend partly on the nature and extent of the growth but in great part on the care and skill of the operator. With an account of paraplegia due to hydatid disease and its treatment these valuable lectures ended.

Three Decades of Scientific Work in Oxford (1650-1680).

THE middle of the *sixteenth century saw the* publication of the work of VESALIUS of Padua which laid the *foundation of modern anatomy, and its great* truths were taught by his successors, COLOMBO, FALLOPIUS, and FABRICIUS, *in spite* of ecclesiastical opposition. Through WILLIAM HARVEY the new biological knowledge was transplanted from Italian to English soil. The publication of HARVEY'S work in 1628 is one of the great landmarks of physiological discovery. The latter *half* of the seventeenth century was a fertile period in the progress of natural knowledge by means of observation and experiment, and with it are associated in Oxford the names of ROBERT BOYLE, CHRISTOPHER WREN, and THOMAS WILLIS, and two others, both Cornish men, who were connected with the University of Oxford—viz., RICHARD LOWER (1631-1691) and JOHN MAYOW (1643-1679). Professor FRANCIS GOTCH[1] has written an eloquent discourse on the *work of these* two men, while the Alembic Club of Edinburgh[2] has recently published an excellent *translation* of the medico-physical works of JOHN MAYOW which consist of five treatises written in Latin. JOHN MAYOW was one of the greatest *scientific men of* the seventeenth century, or indeed of any century. LOWER, "that expert anatomist," whose name is still *preserved* in *the name* "tubercle of LOWER," helped in the anatomical work of R. WILLIS who was then professor of natural philosophy in Oxford. In 1665 LOWER *demonstrated* the transfusion of blood from an artery of one *animal into* the vein of another animal, and indeed he was in the *front* rank of experimental *physiologists*. In his work on the heart and on the colour of the blood he accepted HARVEY'S *view of the* circulation of the blood and pointed out that the heart is muscular and, like all *muscles, is able to contract*. He thought that the movements of the heart were dependent on a nervous flow through the vagus nerves going to the heart, for he noticed that ligature of the eighth pair caused the heart beat to become irregular and feeble. This experiment was not repeated until 1845, when the brothers E. H. and W. WEBER showed that these nerves were excited by the application of a ligature, which irritation *caused* inhibition of the heart's activity. LOWER also noticed by means of experiments on animals that the colour of the blood going to the lungs is dusky and bright red after its transit *through the lungs*. *This fact was shown to* MAYOW. He observed the dark following (p. 176): "Sometimes muscular exercise is mistakenly considered as favouring intellectual activity. Yet college presidents are not selected from the ranks of prize-fighters." In discussing Chittenden's diet it is pointed out that a jaded appetite is an automatic signal of excess (p. 184) and that Chittenden is in error in the commendation of from 2500 to 2600 calories as an ample diet for a soldier at drill. As to German beer, it "contains 3 to 4 per cent. of alcohol and 5 to 6 per cent. of extractives. It yields 450 calories to the body, only half being derived from the alcohol, the rest from the dextrose and proteid-like extractives. Here is a material whose 'fattening' properties may be very highly considered." The chapter on food requirements during growth is of interest both to the physiologist and to the physician.

---

[1] Two Oxford Physiologists: *Richard Lower*, 1631 to 1691; *John Mayow*, 1643 to 1679. By *Francis* Gotch, M.A., D.Sc., F.R.S., Waynflete Professor of *Physiology*, University of Oxford.

[2] *Alembic* Club Reprints, No. 17. *Medico* Physical Works. Being a translation of Tractatus Quinque *Medico-Physici*, by John Mayow, LL.D., M.D., 1674. The Alembic Club, Edinbur

The saying of Pflüger that "the atmosphere in which one lives is really the air in our alveoli" is made use of to illustrate the respiratory phenomena at high altitudes. There is a very careful discussion of diabetes. The *piqûre* experiment of Bernard led many to attribute its origin to nervous causes. It is otherwise: (1) either the organism cannot burn sugar, or (2) some tissues may lose their sugar-retaining functions, and therefore the author states that it would be well to distinguish between glycosurias where the "sugar-holding" capacity of organs has been diminished and those in which the "sugar-burning" capacity has been affected.

The author quotes in full Minkowski's rules for gout. In fever, because of the specific dynamic action of proteins, Rubner would restrict the use of proteins and substitute carbohydrates as the source of energy. During the heat of summer decreased protein diet will markedly improve the personal comfort by decreasing the heat production and therefore sweat production. Obese people work under great disadvantages in a hot and moist climate; the profuse perspiration explains the desire for water to drink. In connexion with the chapter on purin metabolism we have failed to find a reference to the work of I. Walker Hall. As to gout, "clinical experience teaches that the predisposing causes are excessive eating, little muscular exercise, the abuse of alcoholic beverages, and lead poisoning."

In spite of the necessarily numerous tables of figures the work is excellent reading and represents a careful study of the modern facts of metabolism.

LIBRARY TABLE.

The Chemical Basis of Pharmacology. By FRANCIS FRANCIS, D.Sc., Ph.D., Professor of Chemistry, University College, Bristol; and J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxon., Demonstrator of Physiology, University College, Bristol. London: Edward Arnold. 1908. Pp. 372. Price 14*s.* net.—The appearance of this book is a sign of the progress that is being made in a much-needed direction—the replacement of empirical by rational methods in pharmacology. There is no study of greater interest or importance to general medicine than that of the relationships existing between the chemical structure and the physiological action of drugs. Much valuable work, as this book shows, has been done, but more remains, and we cordially agree with the authors that the student of medicine should have impressed upon him more than has hitherto been the case the bearing of structure, and especially that of organic compounds, on pharmacology. The quotation from Locke's "Human Understanding," Book IV., Chapter iii., Section 25, which is given on the page preceding the preface, is appropriate. "Did we know," it commences, "the mechanical affections of the particles of rhubarb, hemlock, opium, and a man, as a watchmaker does those of a watch, whereby it performs its operations and of a file which by rubbing on them will alter the figure of any of the wheels, we should be able to tell beforehand that rhubarb will purge, hemlock kill, and opium make a man sleep." It is striking to compare with this some of the modern scientific statements scattered through the pages of this book, such, for example, as the following: "When the amido group replaces a hydrogen atom in the benzene nucleus substances of the nature of aniline result and a completely new and valuable set of pharmacological properties appear; this observation has formed the basis of a large group of so-called antipyretics." "The entrance of a second amido group gives rise to powerfully toxic substances." "The entrance of the hydroxyl group into benzene with the formation of phenol causes a great increase in antiseptic and toxic properties." "In the aldehydes the replacement of oxygen by sulphur is followed by a rise in toxic properties; paraldehyde, for example, does not act upon the heart, whereas tri-thioaldehyde also possessing hypnotic properties is a powerful heart poison.' "The replacement of hydrogen by the halogens causes an increase in narcotic action; thus sodium acetate is quite inert but sodium monochloracetate has pronounced narcotic properties." These few examples serve to show the high purpose of the book and though clinical experience may be the only test of the value of a drug, yet, as the authors point out, the probable physiological action may often be fairly accurately gauged by a consideration of its chemical structure. It seems probable, too, that if greater regard had been paid to the relationship of structure to physiological action it might have been seen how superfluous or unnecessary was the introduction of a great number of synthetic remedies. The book should appeal to all those readers who take seriously to heart the problem of establishing therapeutics firmly on a scientific foundation.

The Illustrated Medical Dictionary. By W. A. NEWMAN DORLAND, A.M., M.D. Fourth edition, revised and enlarged. London: W. B. Saunders Company. 1907. Pp. 836. Price 19*s.* net; with thumb index, 21*s.* net.—This medical dictionary is in every way a sound one and the appearance of a fourth edition proves that its author intends to keep it up to date. We are told that 2000 new terms have been included in the present issue and six new coloured plates are given, including that of the Leishman-Donovan bodies which originally appeared in this journal. The plate of the reconstructed human embryo of 26 days (after F. Mall) forms an excellent diagram. Several well-illustrated anatomical tables are given. We have tested many of the definitions and failed to find an error in them; the pronunciations given should be useful to the student who has become rusty in his Greek. It is embarrassing to watch the growth of medical nomenclature. We wonder how many people when asked, "What is pneumo-thermomassage?" could answer glibly, "The application to the body of hot condensed air that has been medicated."

Atlas der Deskriptiven Anatomie des Menschen. (*Atlas of Descriptive Human Anatomy.*) By Dr. J. SOBOTTA, Würzburg. Third section. Part I., Nervous and Vascular Systems. Part II., Sense Organs and Lymphatics. Munich: J. F. Lehmann. 1907. Part I., M.16; Part II., M.6. *Grundriss der Deskriptiven Anatomie des Menschen.* (*Essentials of Human Anatomy.*) M.16.—The last two instalments, together forming the third section of Dr. Sobotta's atlas, fully maintain the excellence attained by the previous parts. Of the instalments now under notice the first illustrates the nervous and vascular systems, whilst the second is devoted to the sense organs and lymphatics. The illustrations, as before, are beautifully reproduced and are from paintings by Karl Hajek, the mention of whose name is sufficient tribute to their excellence. We note with satisfaction that the colour of the muscles has been considerably toned down in comparison with that adopted in the earlier parts. Of the plates of the vessels and nerves, those illustrating the anatomy of the triangles of the neck and the blood-vessels of the pelvis strike us as being amongst the best and the most useful. The central milk-supply in question Professor HAY attributes it to the return to the farm on April 28th or 29th of a maidservant who had been recently nursing her mother who had been ill with enteric fever. This servant did not herself suffer from enteric fever, nor is it apparently claimed that she was a "carrier" case, but she came directly to the dairy from a non-disinfected house wherein her mother, who still had enteric fever bacilli in her urine, resided and at once began to take part in the work of the dairy. Professor HAY regards the chain of circumstances as completing the proof of the immediate origin of the epidemic in the infection of the milk-supply in question. We should rather hesitate to use the term "proof" and should prefer to regard infection of the milk in the manner suggested as the most probable theory to account for the origin of the outbreak. The epidemic once started was kept alight, it is thought, by secondary cases and the report contains numerous illustrations of what are regarded as "contact" cases. We have no doubt that enteric fever is more communicable from person to person than is generally believed, but of course in connexion with this term "communicable" there have also to be considered cases infected by food contaminated by the patient or the attendant and consumed by other dwellers in the invaded house. This outbreak at Peterhead has been a difficult problem to unravel and Professor HAY is to be congratulated upon the energy and ability which he has displayed in dealing with it, more especially as he was only consulted when the outbreak was apparently on the wane. We are glad to hear that the Peterhead town council is taking active steps with regard to the improvement of the water-supply which is clearly liable at any moment to become specifically polluted; however small may have been the part which it played in the recent epidemic it might otherwise be responsible some day for an outbreak of even greater magnitude. It is useless to waste time in chemical and bacteriological examinations and in discussions as to their meaning while a catchment area is being manured with privy refuse. But how many more towns in Scotland are there with water-supplies in an equally precarious position and how many of them will have to wait until an outbreak of enteric fever draws attention to the circumstance?

Annotations.

"Ne quid nimis."

THE CASE OF CROPPER v. STOKES.

IN another column will be found a forcible but moderately expressed letter from Dr. B. G. Morison setting out the circumstances of the treatment received by Dr. Henry Fraser Stokes, one of the best-known and most respected practitioners in the North of London, at the hands of Mr. Edge, a county court judge. We need not repeat the story, firstly because Dr. Morison's sketch of it contains all the essentials, and secondly because (to the grave disadvantage of Dr. Stokes) every newspaper in England seems to have contained a more or less garbled account of the case. Judge Edge appears to have said that he did not shrink from his responsibilities when he calmly accused a well-known medical man of perjury, but that is exactly what he did do when he refused a request for leave to appeal. He was courageous enough in his own court, where his conduct could not be brought into question, but he was so particularly timid as to what other people might say of his attitude that he has decided to take care that it is not discussed. We understand that Dr. Stokes was represented in this case by the Medical Defence Union. The Medical Defence Union cannot possibly afford to allow the case to remain here. If the Union does not take some steps to see that reparation is made to Dr. Stokes for the treatment which he has received its position will be seriously affected. We suppose it is open to Judge Edge to say publicly that he has made a mistake and has been betrayed into an accusation which is only not laughable because of its cruelty to an honourable gentleman. If nothing can be done by legal procedure, and if Judge Edge makes no attempt to set right the mischief which he has done, we trust that the Medical Defence Union will take the responsibility of telling the true story publicly.

INVALID TRAVEL IN ITALY.

FROM its headquarters in Rome (writes an Italian correspondent) the "Society for Encouraging the Influx of Foreigners" appeals for such hints or indications as may assist it to "welcome the coming," and not prematurely to "speed the parting," guest. It professes to be fully alive to the need for improved railway service, which, to do it justice, it has succeeded in making more punctual, though reform is still needed in other details. Prominent among these latter are the means available on departure and arrival for the transport of the physically infirm from the cab or hotel omnibus to the station, and from this to the compartment in the railway carriage. As it is, the bed-ridden or the cripple is liable to undergo extreme discomfort before being fairly accommodated for his journey—nothing but previous arrangements of an elaborate and costly kind sufficing to save him from exposure that he would rather not court or from pain that he would gladly be spared. Even in the case of sufferers, let us say, from rheumatoid arthritis, whose walking power is so impaired that they have to be carried, their fate on an arrival or a departure platform is often such as to evoke commiseration. No skilled help is at hand unless provided for in advance by complicated and often expensive "combinazioni"; delay, frequently trying when the train is being precipitately evacuated or wildly taken by storm, is quite inevitable; and when after a long wait, either in the open air or under a draughty "tettoia" (roof) exposed to the cold if not the rain, the sufferer at length succeeds in getting a "portantina" (sedan chair) and "facchini" (porters) capable of carrying it, he is charged so exorbitantly and, rather than make a "scene," has to pay such a round sum that he is prone to make a mental vow never to incur such another experience. Few English-speaking practitioners in Italy can fail to recognise the picture, just sketched, of what the lame, the halt, or the bed-ridden have often to endure, and this in a country which justly boasts of its "Misericordia," its "Croce Verde," and its other organisations, some of them of great antiquity, for lifting, carrying, and depositing the physically incapable or infirm. The transport available for invalids at railway stations or landing piers is only such as porters can supply—porters often rough, malodorous, and strong in language rather than in limb, who insist on their extortionate demands and when remonstrated with reply gruffly: "Non c'è tariffa per ammalati" (There is no tariff for invalids). Much has been done to bring the Italian railway service up to the standard of that of other European Powers but there is much still to do, particularly in the interests of that steadily increasing contingent of the "grand' armée" of travel which is year by year attracted to the southern shores of the Mediterranean, whose presence in Italy during winter and spring is a national asset, and whose departure

THE LANCET.

LONDON: SATURDAY, APRIL 4, 1908.

The Surgery of the Spinal Cord and its Membranes.

THE lesions of the spinal cord are many but only a few of them are amenable to surgical treatment. Yet the scope of surgery in this region of the body is steadily extending and with the increased aid afforded by improvements in diagnosis the results in the future will be better even than those obtained at present. Mr. DONALD J. ARMOUR took for his subject in the Hunterian lectures, which he has recently delivered at the Royal College of Surgeons of England and which have been published in THE LANCET,[1] the Surgery of the Spinal Cord and its Membranes and all who have worked at the surgery of this portion of the body will read with great interest the reports of his lectures. It was quite impossible for him to compress into these lectures all that could be said on the surgery of the cord and its adnexa and Mr. ARMOUR was therefore compelled to select certain portions of the subject. He devoted one lecture to spina bifida, one to fracture-dislocation of the spine in so far as it relates to injury of the spinal cord, and in the third lecture he spoke of tumours of the cord.

Spina bifida is a congenital condition of no small importance; if left untreated the majority of cases will go on with certainty to a fatal ending but in some instances at least surgery can offer a chance, and often much more than a chance, of a complete cure of the condition. Mere palliative treatment is all that can be employed for many of these patients. MORTON'S injection method, at one time widely employed, was approved by the committee appointed by the Clinical Society of London in 1885; in the report issued by that committee nearly 50 per cent. of cures were reported but the cases which are the most suitable for MORTON'S method are the simple meningoceles and these are the cases which are most suited for excision. Moreover—and Mr. ARMOUR lays stress on this fact—it is impossible, in spite of the indications from translucency described in many of the books, to diagnose what variety of spina bifida is present in any particular case until the sac has been opened. HILDEBRAND and MUSCATELLO have shown that myelocystoceles are often mistaken for simple meningoceles and there can be little doubt what would be the result of injecting MORTON'S iodo-glycerine solution into a myelocystocele. Excision is now almost universally adopted except when that procedure is impossible on account of ulceration and threatening rupture. In such cases as these Mr. ARMOUR considers that injection may be tried. The chief cause of death in untreated spina bifida is a septic meningitis produced by the penetration of micro-organisms through an ulcerated or ruptured sac wall; so, too, after operations on spina bifida the chief cause of death is a septic meningitis caused by an infection of the wound. The utmost cleanliness, the most perfect asepsis, is the first essential for any operation for spina bifida, for if the slightest sepsis is present healing by first intention cannot occur and the result will be failure. When the sac is opened, if no nerve roots are present it is an easy matter to close the sac. If, however, nerve roots are found in the sac they must be dissected off the sac wall and replaced, unless, indeed, they end in the sac, and then they are functionless and they may be removed. The chief contra-indication of the operation of excision is paralysis, especially if there is complete paraplegia with involvement of the sphincters. Sometimes it is true that the paralysis is due to tension of the nerve elements and then if the tension is relieved some improvement may be expected. The cases of partial paralysis may reasonably be looked upon as suitable for operation. The results of excision must be considered in connexion with the results of cases in which no operation is performed. The majority of cases of spina bifida if untreated die during the first year, and especially during the first three months of life. The death-rate of operation is much higher if the operation is performed during the first few months than in those cases in which the operation is postponed till the child has survived for five or six years. In 1905 MOORE collected all the reported cases, 378 in number, though doubtless many operations have never been published and unsuccessful cases are certainly less likely to appear in print than those which have ended favourably. Of these 378 cases, the mortality before 1885 was 30 per cent.; since then the death-rate has been reduced to 24 per cent. The longer that cases are kept under observation after operation the greater the death-rate would probably be. Post-operative hydrocephalus is by no means rare but an explanation of its occurrence is hard to find; it may follow operations for spina bifida which have been apparently entirely successful. In all forms of spina bifida except pure meningocele the prognosis of operation is exceedingly grave but the results of non-operative treatment are graver still.

In his second lecture Mr. ARMOUR dealt with the lesions of the spinal cord occasioned by fracture-dislocation of the spine. In any case where there has been fracture of the vertebral column or dislocation, or a combination of the two, the cord may suffer injury by compression, contusion, laceration, or complete division. Even when extensive injury is present the cord on external examination may show nothing; this fact is obviously of the greatest importance, for the surgeon cannot be absolutely certain of the condition of the cord at an operation. Even complete dislocation with fracture of the upper two cervical vertebræ is not always immediately fatal; this is because of the large size of the neural canal in the cervical region. In the dorsal region extensive injury to the cord follows. The diagnosis between partial and total transverse lesions of the cord is very difficult and Mr. ARMOUR shows that the "classical" signs of a total transverse lesion are very untrustworthy. Even when there is complete paralysis of motion and sensation below the lesion the deduction is not justifiable that the lesion is total, for recovery may follow the occurrence of these symptoms the opportunity of acquiring a much-needed breathing-space to slip from the control of the committee. There is an increasing agitation for establishing "an arbour day" throughout England which shall be celebrated by the planting of trees for the benefit of future generations. This is an excellent movement and should be supplemented by the attempt to save from the axe as many trees at present existing as may be possible, remembering the old proverb in regard to the tree-feller, that a fool in five minutes can destroy the forethought and work of 50 years. Mr. Thomas A. Cook of the Soap Works, Bow, and Mr. George W. Paton of Fairfield Works, Bow, are the joint honorary secretaries. The joint honorary treasurers are Mr. C. E. Riche, London and South-Western Bank, Bow-road, and Mr. W. R. Few, London and Westminster Bank, Bow-road. Any of these gentlemen will gladly acknowledge contributions towards the object in question.

A DARWIN CELEBRATION AT CAMBRIDGE.

ARRANGEMENTS are being made by the University of Cambridge to celebrate on Tuesday, June 22nd, Wednesday, June 23rd, and Thursday, June 24th, 1909, the hundredth anniversary of the birth of Charles Darwin and the fiftieth anniversary of the publication of the "Origin of Species." It is proposed to invite representatives of universities and other learned bodies, together with distinguished individuals, to visit the University on the occasion. A programme of the celebration will be issued in the near future. The honorary secretaries to the movement are Mr. J. W. Clark, the Registrary of the University, and Professor A. C. Seward, professor of botany in the University.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS, 1908.

THE preliminary announcement has been issued concerning the International Congress on Tuberculosis which is to be held this year in Washington, U.S.A., under the organisation of the American National Association for the study and prevention of the disease, of which Dr. Frank Billings is president, and Mr. Theodore Roosevelt, Mr. Grover Cleveland, and Professor William Osler are honorary vice-presidents. We have already announced that the Congress will be held on Sept. 24th and the two following days under the auspices of the United States Government, seven of its nine departments having petitioned the House of Congress for authority and means to participate in the conference, while the Department of State has been authorised to invite the governments of other countries, through their ministers, to send representatives to the Congress. The programme is divided into seven sections, which are: (1) Pathology and Bacteriology; (2) Clinical Study and Therapy—Sanatoria, Hospitals and Dispensaries; (3) Surgery and Orthopædics; (4) Tuberculosis in Children, Etiology, Prevention, and Treatment (a full syllabus of the work of this section is given); (5) Hygienic, Social, Industrial and Economic Aspects of Tuberculosis; (6) State and Municipal Control; and (7) Tuberculosis in Animals, and its Relation to Man. An exhibition will gather illustrative material, appliances for treatment and so forth, from all parts of the world, including literature on tuberculosis, and readers of THE LANCET[1] have already been informed of the nature and conditions of the prizes offered in connexion with this exhibition. They may like to be reminded of the terms of membership, for it is our hope that Great Britain, which has throughout been in the van in dealing with tuberculosis, will be well represented at the Congress. Active members will pay a fee of $5 and will receive the full set of published transactions. Associate members, who pay $2 only, do not receive the transactions or vote in the Congress. An entertainment and a transport committee have been formed, which will enable visitors to the Congress to receive the benefits of special rates of travel, and a tour of many of the principal cities of the Eastern States, lasting from Sept. 21st to Oct. 10th, and including a visit to Niagara, is to be arranged. Those of our readers who have experienced American hospitality will rest assured that they will be welcomed in a very practical manner by their brothers across the ocean if they can spare the time to make an extended summer holiday. Applications for membership or for further information should be made to the Secretary-General, Dr. John S. Fulton, Colorado Building, Washington, D.C.

THE PURIFICATION OF POTABLE WATER.

IN the *Union Pharmaceutique* a simple and apparently harmless method is given for purifying potable water. The method, as given by M. Célestin Hy, is based on that originally devised by M. Girard and M. Bordas. The water to be purified is first treated with a powder consisting of one equivalent of potassium permanganate and sodium carbonate and slaked lime, of each seven equivalents. After an interval of five minutes eight equivalents of anhydrous ferrous sulphate are added. The method is based upon the fact that potassium permanganate in an alkaline solution oxidises organic matter and destroys micro-organisms, the sodium carbonate precipitates any calcium sulphate that may occur naturally in the water, and the calcium hydrate precipitates any bicarbonate of lime that may be present. On adding ferrous sulphate the excess of permanganate is removed in the form of a dense precipitate. The water as drawn off from the precipitate is very pure and limpid and contains only a very small amount of the sulphates of potassium and sodium. The presence of these salts is not at all objectionable. In the case of the water of the Seine, containing a great number of bacteria, including the colon bacillus, M. Hy found that this process produced a perfectly sterile water. There is very little danger of using an excess of either of the powders. An excess of the powder containing potassium permanganate would impart to the finished product a noticeable pink colour, while an excess of iron would be precipitated partly by the sodium carbonate and partly by the calcium carbonate resulting from the first reaction.

THE TREATMENT OF SCARLET FEVER BY SERUMS.

SEVERAL attempts have been made to treat scarlet fever by serums, the serum of convalescents having been tried without much success and also an anti-streptococcic serum, the latter owing to the belief that the causal agent in the disease was a streptococcus. It is, however, more probable that the streptococci found in scarlet fever are a secondary infection, and though they may be the cause of some of the complications met with in severe cases, and anti-streptococcic serum may therefore be of some use, it can hardly be regarded as a specific remedy. The actual infective agent is at present unknown, the protozoal organisms described by Mallory not being as yet generally accepted. Recently Marpmann, proceeding on the assumption that the infective agent resided in the scales of the desquamative stage of the disease and that the toxins formed were present in the blood and urine of patients, has used these substances for injecting animals and has obtained from them a serum which, he states, is both protective against the disease and curative of it when it has developed. Two separate serums are manufactured, one prophylactic and the other curative. The difference in the respective modes of preparation is not stated in the articles dealing with the remedy which we have been able to obtain. From the brief account given above the serum would seem

THE LANCET.

LONDON: SATURDAY, APRIL 4, 1908.

The Surgery of the Spinal Cord and its Membranes.

THE lesions of the spinal cord are many but only a few of them are amenable to surgical treatment. Yet the scope of surgery in this region of the body is steadily extending and with the increased aid afforded by improvements in diagnosis the results in the future will be better even than those obtained at present. Mr. DONALD J. ARMOUR took for his subject in the Hunterian lectures, which he has recently delivered at the Royal College of Surgeons of England and which have been published in THE LANCET,[1] the Surgery of the Spinal Cord and its Membranes and all who have worked at the surgery of this portion of the body will read with great interest the reports of his lectures. It was quite impossible for him to compress into these lectures all that could be said on the surgery of the cord and its adnexa and Mr. ARMOUR was therefore compelled to select certain portions of the subject. He devoted one lecture to spina bifida, one to fracture-dislocation of the spine in so far as it relates to injury of the spinal cord, and in the third lecture he spoke of tumours of the cord.

Spina bifida is a congenital condition of no small importance; if left untreated the majority of cases will go on with certainty to a fatal ending but in some instances at least surgery can offer a chance, and often much more than a chance, of a complete cure of the condition. Mere palliative treatment is all that can be employed for many of these patients. MORTON'S injection method, at one time widely employed, was approved by the committee appointed by the Clinical Society of London in 1885; in the report issued by that committee nearly 50 per cent. of cures were reported but the cases which are the most suitable for MORTON'S method are the simple meningoceles and these are the cases which are most suited for excision. Moreover—and Mr. ARMOUR lays stress on this fact—it is impossible, in spite of the indications from translucency described in many of the books, to diagnose what variety of spina bifida is present in any particular case until the sac has been opened. HILDEBRAND and MUSCATELLO have shown that myelocystoceles are often mistaken for simple meningoceles and there can be little doubt what would be the result of injecting MORTON'S iodo-glycerine solution into a myelocystocele. Excision is now almost universally adopted except when that procedure is impossible on account of ulceration and threatening rupture. In such cases as these Mr. ARMOUR considers that injection may be tried. The chief cause of death in untreated spina bifida is a septic meningitis produced by the penetration of micro-organisms through an ulcerated or ruptured sac wall; so, too, after operations on spina bifida the chief cause of death is a septic meningitis caused by an infection of the wound. The utmost cleanliness, the most perfect asepsis, is the first essential for any operation for spina bifida, for if the slightest sepsis is present healing by first intention cannot occur and the result will be failure. When the sac is opened, if no nerve roots are present it is an easy matter to close the sac. If, however, nerve roots are found in the sac they must be dissected off the sac wall and replaced, unless, indeed, they end in the sac, and then they are functionless and they may be removed. The chief contra-indication of the operation of excision is paralysis, especially if there is complete paraplegia with involvement of the sphincters. Sometimes it is true that the paralysis is due to tension of the nerve elements and then if the tension is relieved some improvement may be expected. The cases of partial paralysis may reasonably be looked upon as suitable for operation. The results of excision must be considered in connexion with the results of cases in which no operation is performed. The majority of cases of spina bifida if untreated die during the first year, and especially during the first three months of life. The death-rate of operation is much higher if the operation is performed during the first few months than in those cases in which the operation is postponed till the child has survived for five or six years. In 1905 MOORE collected all the reported cases, 378 in number, though doubtless many operations have never been published and unsuccessful cases are certainly less likely to appear in print than those which have ended favourably. Of these 378 cases, the mortality before 1885 was 30 per cent.; since then the death-rate has been reduced to 24 per cent. The longer that cases are kept under observation after operation the greater the death-rate would probably be. Post-operative hydrocephalus is by no means rare but an explanation of its occurrence is hard to find; it may follow operations for spina bifida which have been apparently entirely successful. In all forms of spina bifida except pure meningocele the prognosis of operation is exceedingly grave but the results of non-operative treatment are graver still.

In his second lecture Mr. ARMOUR dealt with the lesions of the spinal cord occasioned by fracture-dislocation of the spine. In any case where there has been fracture of the vertebral column or dislocation, or a combination of the two, the cord may suffer injury by compression, contusion, laceration, or complete division. Even when extensive injury is present the cord on external examination may show nothing; this fact is obviously of the greatest importance, for the surgeon cannot be absolutely certain of the condition of the cord at an operation. Even complete dislocation with fracture of the upper two cervical vertebræ is not always immediately fatal; this is because of the large size of the neural canal in the cervical region. In the dorsal region extensive injury to the cord follows. The diagnosis between partial and total transverse lesions of the cord is very difficult and Mr. ARMOUR shows that the "classical" signs of a total transverse lesion are very untrustworthy. Even when there is complete paralysis of motion and sensation below the lesion the deduction is not justifiable that the lesion is total, for recovery may follow the occurrence of these symptoms has the arterial system been thoroughly examined. Lesions of the heart associated with acute infections have received much attention but the arteries have been overlooked. The latest investigation of the influence of acute infections on the arteries was published by Wiesel in July, 1906. It is based on 300 necropsies made at the Franz Josef Hospital, Vienna. Among them were 80 cases in which the beginnings of arterio-sclerosis were observed. The subjects were young, many of them infants. Macroscopic and microscopic observations were made of the condition of the central and peripheral vessels at the beginning and height of the fatal illnesses which included diphtheria, scarlet fever, measles, pneumonia, influenza, sepsis, pyæmia, osteomyelitis, suppurative otitis, enteric fever, cerebro-spinal fever, mushroom poisoning, and other conditions. Macroscopic changes appeared occasionally, usually between the sixth and tenth day as minute yellowish patches in the aorta, carotids, and coronaries. In a few cases minute projections of calcareous deposits were visible. Microscopic degenerative changes were almost constant not only in the large trunks but in the end arteries.

CARE OF THE FEEBLE-MINDED.

AN interesting paper by Miss Mary Dendy, the lady inspector of the special schools for the feeble-minded, was read recently before the members of the Manchester Statistical Society, on the Problem of the Feeble-minded. The point on which she insisted was that, unless the result of injury, weakness of intellect was incurable and would tend to be handed down to the offspring of the sufferer. Therefore it was "the most pressing of all the social problems of our time" and from its nature "it was the only one which justified them in overriding the responsibility of the parent for his child." Most of the vices claiming the attention of sociologists resulted from weakness of intellect—"infantile mortality, child neglect, underfeeding (or improper feeding), drink, unemployment, purposeless crime, assault, murder, and theft." This is a strong indictment but in the main it will not be disputed. It was responsible for a large proportion of the unemployed, for if after leaving the special schools they get work the best of them only keep it as long as they can be considered boys and are turned adrift when a man's wages have to be given. Miss Dendy said it was unfortunate that in this country this condition was considered a curable disease which could be set right by differential treatment. From this fallacy came statements as to children being returned to ordinary schools in a normal condition, the fact being that in some towns "many of the children admitted to the special schools were not really weak-minded." The facts put together by the Birmingham After-Care Committee showed that, short of permanent detention, the very best of the trained feeble-minded were employed only irregularly and that the great majority of them were unemployed or criminal. The teaching of useful habits of imitation was advocated in lieu of the habits of reason which served the ordinary mind. This line of argument leads up, of course, to the necessity of permanent detention and control, so that feeble-mindedness and its attendant evils shall not spread from more to more. "Residential or permanent schools should be provided and children should be admitted to them at an age to be determined in every case by the medical man in charge." The discussion that followed showed a general acquiescence in the opinions expressed in the paper but Dr. J. Niven suggested an important question, whether, supposing the whole of the evidently feeble-minded were removed and permanently taken care of, the fountain would be materially affected. "It not infrequently happened that only one child in a family was obviously defective and in those cases it followed that if such a one was removed others were left behind whose defects were not so noticeable." Still, allowing for the loophole which Dr. Niven discovered, it is certain that the multiplication of these unfortunates would be considerably checked, if not altogether prevented. There would always remain the danger, more or less in degree, that abuses might arise and that some might be shut out from their normal career by being kept in a permanent establishment of the feeble-minded. Careful inspection would have to be provided.

THE CREMATION SOCIETY OF ENGLAND.

AN extraordinary general meeting of the Cremation Society was held on March 23rd, Sir Charles A. Cameron, Bart., being in the chair, to consider the substitution of a new draft of rules for the existing rules of the society. Sir Charles Cameron gave in his speech an interesting epitome of the history of the society, speaking of the hostility which its foundation in 1874 aroused on every side, of the support afforded to it by the founder, the late Sir Henry Thompson, and also by the late Sir Spencer Wells and the ninth Duke of Bedford, whose joint generosity resulted in the erection and equipment of the crematorium at Woking in 1879. He narrated how it was six years before the judgment in the Welsh Druid case allowed of its employment and how the first cremation took place in March, 1885. In five years only 100 bodies were cremated in Great Britain, but the numbers steadily increased until in 1900 the office was performed 301 times at Woking. Last year 705 cremations took place in the 13 crematoriums throughout the kingdom. After reviewing the sanitary advantages and disputing the ethical drawbacks of cremation, Sir Charles Cameron went on to regret the fact that the practice had hitherto been limited to the upper and professional classes and pointed out that a cremation need cost the poor no more than they habitually spend on a decent funeral. He then proposed that the present single payment of 10 guineas, which constitutes a person a life member of the Cremation Society and entitles him to cremation without fee after his death, should be replaced by a single payment of 5 guineas or six annual payments of 1 guinea each, and further that the cremation should be paid for by the society at any crematorium in the kingdom. He hoped that when the number of cremations was such that the furnaces could be kept continuously heated, the fees would be reduced even more. Sir Charles Cameron's motion that these new rules should be substituted for the old was seconded by Sir Herbert Thompson, Bart., and carried unanimously by the meeting. Many of our readers will be glad to know of the society's progress and will wish it a still more rapid extension of its sphere of influence. It seems possible that the growth of city populations may ultimately necessitate general cremation as the solution of the problem of disposing of the dead. On sentimental grounds many will prefer for the means by which their bodies shall be resolved into their constituent elements a process the name of which, by a singular analogy with the Greek πῦρ, strongly suggests purification, to the more usual process which is uncompromisingly putrefaction, but, on the other hand, the biological aspect of the question must not be forgotten. Would the great elemental vegetable-animal cycle run risk of disturbance by the spoliation of the soil of a bulk of its wonted organised enrichment, or would the nitrifying bacteria rise equal to the occasion and derive compensatory toll from the atmosphere? It is a question that is not unworthy of consideration in respect of the expediency of cremation. Its social safety would seem to be assured by the regulations for death certification to which cremation has been made subject, but it must not be forgotten that the Druce *canard* could not have been so thoroughly falsified if venous colour of the blood in suffocation and noticed that the bright red colour could be restored if air was blown through the lungs—in the absence of respiratory movements—so that the air alone was the cause of the change of hue. Shed blood, he saw, became bright red on the surface, and from his observations and experiments Lower concluded that the purpose of the respiratory movements was to bring air to the blood and to make that fluid fit for the heart and other organs—a quality denoted by its redness. The blood absorbs air as it passes through the lungs, and when the "air has escaped into the parenchyma of the viscera the venous blood being deprived of it appears more dusky and black."

But a greater than Lower was Mayow whose books were not much noticed in his own time and indeed a little later they seemed to have been almost forgotten. S. Hales is the only writer of the eighteenth century who refers to them in his "Vegetable Statics" (1727). They were reprinted in Paris, Geneva, Jena, and the Hague. But after the great revolution in chemical theory which followed the discovery of oxygen by Priestley and Lavoisier Mayow's work was unearthed and it was seen that the new chemistry was to be found in this old and largely forgotten work. Thomas Beddoes in 1790, Scherer in 1793, and G. B. Yeats in 1798 set forth the claims of Mayow, but these attempts to make known Mayow's claims met with no great success. Mayow set forth that air is impregnated with a vital, igneous, and highly fermentative spirit and he begins his fifth treatise with a history of nitre, this wonderful salt which makes no less noise in philosophy than in war and fills the universe with its sound. The nitro-aerial salt obtained from nitre becomes food for fires and also passes into the blood of animals by respiration, and is "also the primary instrument of life and motion not only in plants but also in animals." He proved by beautiful and convincing experiments that air contains this special "nitro-aerial" constituent which could unite with what was called salino-sulphurous matter—what may be called the combustible principle, without any suggestion that it contains sulphur in the modern sense of this term. Starting from this fact Mayow proved that something was taken from the air by the respiration of animals—this was his nitro-aerial constituent—and this it was and not the air as a whole which was a necessity of life; the great bulk of the air was not necessary, and this small part was as necessary for life as for combustion. In our tissues a process resembling combustion, as shown by the production of animal heat, was continually going on. He concluded that it is in the muscles that this animal heat is chiefly produced. It was not until 1845 that Helmholtz demonstrated that muscular motion was associated with the oxidation of carbon compounds and the production of heat. One of Mayow's most striking observations is that the nitro-aerial supply to the fœtus must be provided by the respiration of the mother and pass from her blood from the maternal part of the uterine wall. What he failed to recognise was the product of the combustion in the tissues—viz., the giving out of carbon dioxide, or "fixed air," which was discovered by Black in 1752.

The study and teaching of history have of late years entered upon a new phase. Many of the best books on history are not in the words of any modern writer but consist of carefully collated extracts from the writings of men who lived in the time with which the particular period treated deals. There are two admirable modern histories of England appearing in instalments, and both show the qualities of learning and philosophical research, but apart from these our historical reading is better conducted by the help of documents written at the times of the events portrayed. Such works as "Leading Documents of English History" and the valuable series entitled, "English History by Contemporary Writers," bring before us our "rough island story" in a more lifelike manner than even the brilliant antitheses of Macaulay. And so, too, with the history of science and of those branches of it with which we as medical men are the more concerned. As Professor Gotch remarks: "The study of the lives and works of our predecessors is as imperative for scientific men as it is for historians, whilst the duty of undertaking it receives an additional sanction, when, as in the case of Lower and Mayow, their deeds lie buried with their bones in tombs which have been suffered through neglect to fall into decay."

The Outbreak of Enteric Fever at Peterhead.

Reputations may be of the enviable or of the unenviable order, and up to quite recently the fishing town of Peterhead on the rock-bound coast of eastern Scotland, northwards of Aberdeen, has been almost world-renowned for its vast herring fishery, an industry which in years gone by was preceded by that of whaling. Now, unfortunately, it has established an unenviable notoriety for enteric fever, and the side-lights which have been thrown upon its sanitary condition by the detailed investigation which has been made by Professor Matthew Hay make us wonder why its inhabitants have for so long escaped other visitations of a similar nature. From May to October of last year there occurred no less than 425 cases and 23 deaths in this population of some 16,000, the number of cases varying from 30 to 40 per week during the months of May, June, and July. The prolonged duration of the outbreak appears to us to have been one of its most remarkable features, as in this respect it is somewhat unlike other outbreaks. As was to be anticipated, the investigation of this epidemic was beset with many difficulties, partly owing to the stress of administrative work consequent upon the outbreak and partly owing to the difficulty of obtaining accurate data as regards certain particulars. There appears to have been no question whatever as to the fact that the water-supply was, as a whole, open to pollution from the privy and ashpit refuse which was deposited upon parts of the agricultural land from which the water was derived, and it is clear, bearing in mind ambulant cases of enteric fever, that at any time specific pollution may have reached the water. Still, Professor Hay furnishes evidence which points to the conclusion that the water was not a potent factor in the spread of the disease, although in the first instance he evidently regarded the outbreak as being water-borne. The case against the milk was, however, a stronger one and Professor Hay is inclined, on the whole, to regard the outbreak as having in the first instance been milk-borne and as having been subsequently kept going by "contact" or secondary cases. With reference to the actual infection of the chauffeurs and whose cars are kept away from their residence. The assurance that none of the petrol one pays for is wasted will surely recompense for the cost of this accessory.

Another useful article for the man who drives and looks after his own car is the "Pushon" instantaneous pump connexions which do away with all adapters and twisting swivel joints and when pushed over any make of tyre valve instantly and automatically form an air-tight joint. From past experience I know the trouble which ordinary pump connexions are so I can welcome and recommend the "Pushon."

The airship section in the gallery contained a model of Mr. Henry Farman's aeroplane and a Spencer airship, but I fear it is premature to consider the purchase of one of these for medical work, though in years to come they may be as popular with the profession as cars are now!

THE "FASTING CURE" IN WANGANUI NEW ZEALAND.

WE have received from Dr. Robert H. Bakewell (Surgeon-Captain, Army Medical Department) an interesting series of papers which he has published in a New Zealand journal, supplemented by a short report which he has prepared for us on the proceedings of a small sect of "health cranks" who arose during last year in Wanganui, New Zealand, and have excited considerable interest in that colony. The cardinal principle of their strange doctrine is that mankind owes the ills of its flesh to eating, and they propose as a universal panacea the abstention from food for periods of two or three weeks at a stretch, the victim going about his daily work during the term of his self-inflicted fast. Dr. Bakewell devotes some columns to the origin of this "treatment," and of this we need say little more than that it is American and sprang from the brain of a Dr. Dewey of the University of Michigan in the form of a book which he called "The True Science of Living." One extract from the book will suffice: "When death occurs"—i.e., under the system—"before the skeleton condition is reached, it is always due to old age or some form of disease or injury and not to starvation." If this wild scheme had not gone beyond print we should hardly have noticed it but it is interesting to record that it has reached New Zealand and has been ardently adopted by a band of zealots in Wanganui. Dr. Bakewell's attention was called to these people by the personal narrative of one of them, in which he gave a subjective account of a 25 days' fast, which was widely published in New Zealand. Our correspondent was exceedingly sceptical of the story and last December he proceeded to the new faddists' Mecca to assure himself of its truth or falsehood. He found evidence which he considers convincing that eight people had voluntarily undergone fasts of a fortnight and longer, one of whom, a Maori chief, had died, as it was said, from "blood poisoning" shortly afterwards. The remainder of the people were white men, six of whom Dr. Bakewell saw, although they were not actually fasting at the time. He writes: "After hearing all the evidence, after minutely examining and cross-examining them, I found it so difficult to believe that these six persons, all occupying the respect of their fellow townsmen, could without any conceivable object enter into a conspiracy to utter such improbable lies that I found it easier to believe in the fasts themselves." With regard to the examination of them it may be said in a word that though the fasters thought they were the better for their performance Dr. Bakewell says he would not have passed one of them for insurance as a first-class life, and he noted particularly a dangerous heart weakness. They acknowledged losing weight at the rate of about a pound a day during the fast. The men all stated that the mouth and tongue became covered with a thick fur and that the breath was very offensive; further, that the sexual instinct was entirely absent during the fast. One man stated that after 35 days during which the bowels never acted he passed one most offensive evacuation, and at the same time, or on the same day, vomited most offensive matter. Some of them endured tortures of headache and depression during a few days but subsequently regained their comfort. They took water only, with the exception of lemon juice; one man confessed to an occasional "nip of milk in soda-water."

Dr. Bakewell subsequently had an opportunity of observing one of the devotees in the course of his "cure" and has prepared the following note about his condition:—

> It will be observed that in no case was I able to see a person actually fasting at Wanganui. But since then I was visited at my residence near Auckland by a former patient and old acquaintance, not as a patient but simply because he knew I was interested in the subject. On his first visit he told me that he had been absolutely fasting, except from water, for four days. The first day he took no water even, but this was followed by acute pain in the lumbar region and the passage of a large quantity of uric acid and urates. This was relieved by drinking copiously of water. I had known my visitor for at least 20 years. He had always the appearance of a florid complexioned, rather over-stout man. Latterly he has very greatly diminished in bulk. On my first glance at him I was struck with the grey earthy pallor of his face, destitute of every vestige of healthy colour. He was bathed in a cold sweat, which literally poured from him; his wrists were wet; his pulse was 60, with intermissions of very long duration every 15 beats. He expressed himself as being, with the exception of slight lumbar pain, "perfectly well," although the exertion of walking from the electric tram station to my house—a distance, which I measured myself after he had gone, of only 237 paces all down hill—had plunged him into this cold sweat. He came again two days afterwards, having continued the fast against my strong advice. His pulse was feebler and intermissions took place after every third or fourth beat. I urged him to take some food, but he refused, stating, however, that he intended to break his fast when he returned home. His face was even a darker earth-tint than on the previous visit. I obtained a drop of blood, which I examined immediately under an ⅙ in. power. The red corpuscles were abundant, but much smaller than normal. After a most careful search for half an hour I failed to find even a single leucocyte. Mr. —— not having visited me again, I have been unable to make any further examination of his blood.

Dr. Bakewell incloses extracts from American literature claiming something like the rejuvenation of a man as the result of a 45 days' fast, but he gives strong reason for doubting the accuracy of the story. He has, we think, established the *bona fides* of these Wanganui fanatics. The most interesting thing is that they were able to go about their work during their prolonged abstinence from food and in only one case was hunger a prominent symptom. His conclusion is that "there is some psychic force of which we know nothing, or little, at work which sustains them." At any rate the "fasting cure" of these New Zealanders is not without interest to the physiologist.

MEDICINE AND THE LAW.

A Prescribing Druggist and a Death from Opium Poisoning.

AN inquest held recently by Mr. Luxmore Drew at Hammersmith showed the following facts. A plasterer, Richard Smith, working at the building connected with the coming Anglo-French Exhibition, complained of diarrhœa and was given a dose of a mixture kept for the purpose by the St. John Ambulance Corps at the works. This occurred on March 11th and Smith did not resume work but remained at home, still suffering from diarrhœa and without medical attendance until March 14th, when his wife asked a druggist, James Thomson, of 161, Goldhawk-road, for "two pennyworth of composition powder" for him. In the course of the discussion which followed the druggist appears, from her evidence at the inquest, to have told her that what she asked for would not be of any use as her husband had been ill for so long, and she then asked him to "make her up something." He accordingly gave her a bottle of what she spoke of as diarrhœa mixture, labelled with directions to the effect that one-eighth part of its contents was to be taken every hour until the diarrhœa ceased. The word "poison" did not appear on the label, nor was there any warning that the *dose* named should not be exceeded. The mixture, according to the evidence of the druggist, contained with other ingredients 80 minims of tincture of opium. Smith, on his wife's return, not only took a dose but finding that it made him feel more comfortable took two more within an hour of the first. This was apparently in the evening and by the next morning he had emptied the bottle. During that day he was very drowsy and in the evening a medical man, Mr. C L Batteson, was summoned. According to his evidence he did not find the patient drowsy but was given a history of diarrhœa, mention being made of a bottle of medicine from a druggist, as to which he did not press any inquiry but concluded that the man was suffering from a chill and prescribed chalk and opium to be taken in doses each of which would contain about two minims of opium. On the following day Mr. J. Batteson saw the patient and stopped the medicine ordered by his son Mr. C. L. Batteson, giving a prescription containing strychnine. According to his evidence he found that the diarrhœa had stopped and considered that the for other climes she has as much to dread as (for instance) the abandonment of the "Brindisi route" for that other one by the Balkan States and Salonica.

THE SERPENT OF ÆSCULAPIUS AND SNAKE-WORSHIP.

IT has been pointed out by Dr. Boudin[1] that the worship of the serpent was so universal in antiquity that all temples came to be known as "draconia," serpent houses. However that may be, serpents were kept in many of the temples of antiquity, notably in those of Apollo, whose son Æsculapius is represented in ancient statuary carrying a serpent entwined round a staff or round his arm. The serpent, indeed, came in time to be the special mystical emblem or symbol of the Æsculapian art. The serpents of the ancient Greek temples were in all probability relics of that primitive serpent-worship which was at one time universal among prehistoric peoples and has not died out among many savage races at the present day. As "Voodoo" or "Obi" serpent-worship is still said to linger in the West Indies among the descendants of the less civilised negro slaves. In Hayti especially, where negroes were dumped down from Africa by the old slave-traders and were kept in reserve before being sold to masters in the surrounding islands, Voodoo has defied Roman Catholic missionaries and priests for ages. A French naval officer who visited the court of the Haytian potentate Soulongue in 1849 describes a Voodoo ceremony where cannibalistic and other orgies were indulged in. It is noticeable that the cock and black goat which were solemnly eaten on this occasion were both of them sacred to Æsculapius. Hence we may infer that the Æsculapian cultus was originally an innocent form of Voodoo and at the same time a primordial religion. The extreme antiquity of serpent-worship seems, indeed, to be hinted at in Genesis, where the Devil appears in the guise of the snake-god intent on the ruin of man. In the story of the Brazen Serpent healing qualities are attributed to the image.

HYSTERO-EPILEPSY IN A YOUNG MAN.

THE condition described in great detail by Charcot and his pupils under the name of hystero-epilepsy is one but rarely met with in this country and even in some of the cases recorded the phenomena did not follow the typical sequence. We have received a copy of a paper by Dr. W. Howells, read before the North Glamorganshire and Breconshire division of the South Wales branch of the British Medical Association, describing an example of this condition observed in a young man in his twenty-first year. The patient was of healthy appearance and of muscular build. He was apparently of somewhat erratic and unstable temperament, his memory was very defective, and he was at times passionate and vindictive. Having worked for two years as a miner he became subsequently baggage porter to a travelling concert troupe. He was of Bohemian and licentious habits and of sensual aspect. The family history revealed that his maternal grandmother was alcoholic and also violently hysterical, stigmata which were transmitted to the mother of the patient who, however, was himself not intemperate in regard to alcohol, being practically an abstainer. About four months before he was seen by Dr. Howells he had two fainting fits but otherwise he had not suffered from any serious illness. He showed no indication of organic visceral disease and very few hysterical stigmata, the only conditions found being defective vision with the right eye and some deficiency in the colour sense. The attack which Dr. Howells saw occurred after excessive sexual indulgence and was ushered in by a slight fit on Monday, in which he arched his back and stretched out his limbs. On Tuesday, after some violent exertion, he had several more fits of similar character but remained free until Thursday, when he had a very violent fit, after which he was seen by Dr. Howells for the first time, who found him conscious and coherent but very tender about the right groin, palpation in this region inducing a fit. Between Thursday evening and the following Sunday 80 more or less severe fits occurred, all presenting the same general features. The attacks were readily excited by the administration of food, drink, or medicine, by the striking of a clock, and by any noise. The tongue was not bitten in the fits and there was no involuntary micturition or defæcation. The sequence of the fits was as follows. There was first a period of semi-consciousness and simulated catalepsy followed by an interval with hysterical manifestations. During this period the pupils were dilated, afterwards they gradually contracted and the eyes rolled slowly upwards, ushering in the stage of violent convulsions. There was usually marked opisthotonos and sometimes the body would assume an arc of a circle towards the right. The convulsive stage was followed by a period during which the patient made curious pantomimic gestures "illustrative of his Bohemian life." After the Sunday evening no further attacks occurred. The patient was able to talk intelligently but appeared to have no recollection of his attacks. A few days afterwards he was able to proceed home. Dr. Howells saw him some months later but the man then said that he had no recollection of having seen him before, nor did he remember his illness or even the place at which it occurred. He seems to have also forgotten his pecuniary indebtedness to his medical attendant. Subsequently he enlisted in the army and was killed while serving in the South African war. During the 72 hours of his convulsive period he was given 14 drachms of potassium bromide, 11 drachms of bromidia, and 4 of paraldehyde, without any prejudicial effects. Dr. Howells rightly points out that the term "hystero-epilepsy" is a misleading one to apply to these cases, which should be described as hysteria major or, as he would prefer, convulsive hysteria. He also draws attention to some of the special features of the case under his care and notably to the marked immunity shown by his patient during the convulsive period to the effects of powerful depressant narcotic drugs.

A NEW OPEN SPACE FOR LONDON.

WE have already endorsed the appeal issued by the committee the object of which is to preserve part of the Grove Hall Park Estate, Bow, E. This piece of ground, the last available open space in a district where the provision of fresh air is greatly needed, is a portion of a site which originally consisted of about 12 acres of ground planted with trees. Only about three and a half acres now remain, the larger part having been cut up for building land. The London County Council has promised towards the laying out of this space as a public park and children's playground the sum of £4500, besides offering to maintain the property when acquired, while the borough council has contributed £2250. The remainder, about £2250, with the exception of £200 which are now urgently required to save the space from the builder, has been made up by public subscriptions. The Bishops of London and Stepney have given their hearty support to the appeal. The manufacturers of the neighbourhood have given their practical support and financial aid towards the carrying out of the objects of the committee, recognising as business men as well as generous donors that the health of the people is an excellent investment in the long run. As only £200 remain to be subscribed to save the space in question from being appropriated by the builder we cannot believe that those who have at heart the health and well-being of our great and growing metropolis will allow in Hornsey, 10·3 in Tottenham, and 10·8 in Leyton; the rates in the other towns ranged upwards to 24·3 in Devonport and in Rhondda, 24·7 in Middlesbrough, 25·0 in Merthyr Tydfil, and 25·6 in Oldham. The rate of mortality in London last week did not exceed 17·2 per 1000. The 5405 deaths in the 76 towns last week showed an increase of 148 upon the number returned in the previous week, and included 486 which were referred to the principal epidemic diseases, against 400 and 410 in the two preceding weeks; of these, 203 resulted from whooping-cough, 141 from measles, 52 from diphtheria, 38 from diarrhœa, 36 from scarlet fever, and 16 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·6 per 1000, against 1·3 in each of the three preceding weeks; the rate from the same diseases in London was equal to 1·7. No death from any of these epidemic diseases was registered last week in Tottenham, York, Ipswich, King's Norton, or in three other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 4·0 in Sunderland, 4·3 in Croydon, 5·2 in Salford, and 6·1 in Merthyr Tydfil. The fatal cases of whooping-cough in the 76 towns, which had been 134 and 152 in the two previous weeks, further rose to 203 in the week under notice; the highest death-rates from this disease last week in these towns were 2·0 in Sheffield and in Rhondda, 2·5 in Aston Manor, 3·3 in Sunderland, and 3·4 in Merthyr Tydfil. The 141 deaths from measles also showed a considerable increase upon recent weekly numbers, and caused death-rates equal to 2·0 in Burnley, 2·4 in Salford, 2·6 in Croydon, 2·7 in Preston, and 2·9 in Stockton-on-Tees. The deaths referred to diphtheria declined again, however, to 52 from 58 and 62 in the two preceding weeks; this disease, however, caused death-rates of 1·1 in Hornsey and 1·4 in Merthyr Tydfil. The 38 deaths attributed to diarrhœa corresponded with the number in the previous week. The 36 fatal cases of scarlet fever showed an increase of six upon those in the previous week, and included 15 in London, four in Liverpool, three in Manchester and Salford, and two in Newport (Mon). The 16 deaths referred to "fever" corresponded with the low number in the previous week; two were returned in London, in Nottingham, and in Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 16 preceding weeks from 5581 to 3356, had further fallen to 3229 on March 28th; 355 new cases were admitted to these hospitals during the week under notice, against 312 and 378 in the two preceding weeks. A case of small-pox (the first for many months) was admitted to the Metropolitan Asylums Hospitals during last week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 317 and 320 in the two previous weeks, further rose to 340 during the week under notice, and exceeded by 18 the corrected average number in the corresponding week of the five years 1903–07. The deaths directly referred to influenza in London, which had declined from 141 to 68 in the four preceding weeks, rose again to 71 in the week under notice. The causes of only 34, or 0·6 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified last week in Leeds, Bristol, Bradford, Newcastle-on-Tyne, and also in 54 other smaller towns; five uncertified causes of deaths were, however, registered last week in Birmingham, four in Leicester, and three each in Liverpool, Sheffield, and South Shields.

---

[1] Études Anthropologiques, 1864.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·3 and 18·5 per 1000 in the two preceding weeks, rose again to 19·4 in the week ending March 28th, and exceeded by 2·0 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rates last week ranged from 12·6 and 13·8 in Aberdeen and Greenock, to 21·7 in Glasgow and 26·9 in Dundee. The 683 deaths in these eight towns showed an increase of 31 upon the number returned in the previous week, and included 114 which were referred to the principal epidemic diseases, against 97 and 84 in the two preceding weeks; of these, 58 resulted from measles, 22 from whooping-cough, 21 from diarrhœa, seven from "fever," three from diphtheria, two from scarlet fever, and one from small-pox. These 114 deaths were equal to an annual rate of 3·2 per 1000, which was just double the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 47, 46, and 37 in the three preceding weeks, rose again last week to 58, and included 45 in Glasgow, six in Aberdeen, and four in Edinburgh. The 22 deaths from whooping-cough, however, were fewer by two than the number in the previous week; 13 occurred in Glasgow, four in Edinburgh, and two in Greenock. Of the 21 deaths attributed to diarrhœa, an increase of eight upon the number in the previous week, 12 were returned in Glasgow, and three in Dundee. The seven deaths referred to "fever," of which six were certified as cerebro-spinal meningitis and one as enteric, exceeded the low number in the previous week by four, and included four in Glasgow. Two of the three deaths from diphtheria last week were returned in Dundee, and the fatal case of small-pox was registered in Leith. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 142 and 158 in the two preceding weeks, declined to 133 in the week under notice, but exceeded by nine the number returned in the corresponding week of last year. The causes of 19, or 2·8 per cent., of the deaths in these eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 0·6 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·8 and 23·9 per 1000 in the two preceding weeks, rose again to 27·4 in the week ending March 28th. During the 13 weeks of last quarter the death-rate in the city averaged 25·5 per 1000, the mean rates during the same period being only 17·6 in London and 18·3 in Edinburgh. The 207 deaths of Dublin residents registered in the week under notice showed an increase of 26 upon the number returned in the previous week, and included but four which were referred to the principal epidemic diseases, corresponding with the low number returned in each of the two preceding weeks; these four deaths included three from whooping-cough and one from diarrhœa, whereas no death resulted from measles, scarlet fever, diphtheria, "fever," or small-pox. These four deaths from epidemic diseases were equal to an annual rate of but 0·5 per 1000, the death-rate last week from these principal epidemic diseases being equal to 1·7 in London and to 1·5 in Edinburgh. The fatal cases of whooping-cough in Dublin last week exceeded the numbers in recent weeks. The 207 deaths from all causes in the city last week included 29 of infants under one year of age and 68 of persons aged upwards of 60 years; the deaths of elderly persons showed a further increase upon recent weekly numbers. Three inquest cases and two deaths from violence were registered, and 77, or 37·2 per cent., of the deaths occurred in public institutions. The causes of ten, or 4·8 per cent., of the deaths registered during the week under notice were not certified; in London all but two of the 1581 causes of death were duly certified, and in Edinburgh the proportion of uncertified deaths was equal to 5·6 per cent.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Fleet Surgeons: E. C. Cridland to the *Minotaur* on commissioning; and J. D. Hughes to the *Egmont* and for Malta Dockyard. Staff Surgeons: H. H. Gill to the *Terror*, additional; W. H. O. Garde to the *Emerald*; and J. A. L. Campbell to the *Donegal*. Surgeons: A. R. Davidson to the *Actæon*; and T. F. O'Keeffe to the *Minotaur* on commissioning.

Royal Army Medical Corps.

Captain A. F. Carlyon has been appointed for duty in the London District. Captain F. J. Turner has been transferred to Jubbulpore for duty.

Imperial Yeomanry.

Lincolnshire: Surgeon-Major Thomas H. Openshaw, C.M.G., to be Surgeon-Lieutenant-Colonel (dated Feb. 22nd, 1908.

likely to be mainly antitoxic; though if the causal agent of the disease is contained in the epidermal scales it might also possess some germicidal power. It is called "scarlatin" and is administered by the mouth in doses of three to eight minims in milk. Good results are recorded by several continental writers, of whom the most recent is Professor Monti of Vienna, so that a trial of the remedy in the fever hospitals of this country would seem desirable.

THE PEABODY DONATION FUND.

THE munificent donations and bequest of Mr. Peabody between 1862 and 1873 for the better housing of the working classes in London amounted to £500,000, and the forty-third annual report of the governors of this donation fund shows that on Dec. 31st last the amount of the fund had increased to £1,571,252. It is further stated that the fund, with its accumulations since 1873, when Mr. Peabody's bequest brought his total gift to £500,000, "shows an average profit per annum, at compound interest, of almost exactly £3 per cent." Thus the governors of the fund, by the investment of the annual net income, have been able to expend £1,500,279 on land and buildings for the purposes of the Trust, or more than three times the amount of the aggregate donations and bequest. The net income of last year from rents and interest, added to capital account, was £41,343, and the expenditure on land and buildings during the year was £41,543. The rapid and automatic growth of this fund is full of interest and cannot fail to prove a most valuable asset for the promotion of the sanitary condition of the metropolis. At the end of the year this fund had provided for the artisan and labouring poor of London 5586 separate tenements, consisting of 12,913 rooms, including 199 cottages of five rooms, 105 tenements of four rooms, 1833 of three rooms, 2550 of two rooms, and 899 of one room. The mean population of these tenements during the year was 19,737, which constitutes, however, the one disappointing feature of the recent reports of the governors of the fund. On referring to the twenty-fifth report on the fund it appears that at the end of the year 1889 the 11,275 rooms then provided had an occupying population of 20,374 persons, exceeding by 617 the number residing in the buildings provided by the fund at the end of last year. During the 18 years 1889–1907, the number of new rooms provided has not exceeded 1638; notwithstanding this addition the number of residents has declined. This decrease appears to be due: (1) to greater stringency in the prevention of overcrowding in these improved dwellings; (2) to decrease in the number of young children in families residing therein; and (3) to the fact that during recent years the additions to the tenements provided by the fund have been mainly those consisting of more than two rooms. For instance, in the report for 1907 it is stated that 117 five-room cottages out of a total of 154 on the Tottenham estate were ready for occupation in June last; and further, that 64 cottages are in course of erection on the Herne Hill estate and will probably soon be ready for occupation. It seems open to question whether the provision of suburban cottages will, from the point of view of the health of the metropolis, prove as useful as the provision of improved dwellings in central London where so large a proportion of the working poor are bound to reside. Moreover, it is stated in the last issued report that the letting of the five-room cottages on the Tottenham estate "is proceeding very slowly." The beneficial effect of these Peabody Buildings on the health of the residents, in spite of a density of population equal to 635 per acre, may be judged by the fact that the death-rate last year among the nearly 20,000 residents did not exceed 12·2 per 1000, against 14·6 in the whole of London. It appears, moreover, that the proportion of infant mortality in these dwellings did not exceed 58 per 1000 births, against 115, the mean proportion in London. Realising the fact that this fund has more than trebled in the 35 years since 1873 it is difficult to over-estimate its future effect upon the housing of the poor of London and on their health and sanitary condition.

ARTERIO-SCLEROSIS IN THE YOUNG.

IN the *American Journal of the Medical Sciences* for February Dr. F. Fremont-Smith has published an important article on arterio-sclerosis in the young. He reports a case under his own observation and exhaustively reviews the literature of this interesting subject. A male mulatto, aged 32 years, was suffering from obliterative arteritis with gangrene of the toes, which necessitated amputation. His arteries were sclerosed and beaded. He gave a history of syphilis contracted in his eighteenth year. He had a son, aged 12 years, who, by his pinched and haggard appearance, complexion, figure, and carriage, suggested an aged man. Examination showed diffuse sclerosis of all his arteries, with calcification quite as advanced as in his father; the beading could not have been greater at any age. There was no evidence of heart or kidney disease. The boy was mentally bright but physically stunted and thin, and his muscles were undeveloped. The arterio-sclerosis was thought to be due to congenital syphilis. Isolated references to arterio-sclerosis in the young may be found in literature since the beginning of the last century. Portal, in his work on anatomy published in 1803, stated that "rarely the arteries of young persons become ossified." In "Diseases of Arteries," published in 1815, Hodgson described the temporal artery of an infant, aged 15 months, "converted into a complete tube of calcareous matter." Turning to recent literature, Romberg says that in Germany arterio-sclerosis augments with rapidity after the fifteenth year. In 1477 necropsies performed at all ages and in all conditions he found the arteries diffusely thickened in two subjects at the ages of one and 14 years respectively, and in 5·8 per cent. of the subjects between the ages of 15 and 19 years. But not until the recent studies of the pathology of arterio-sclerosis by Ortner, Flexner, Thayer, and others have the frequency and importance of arterio-sclerosis in the young been appreciated. These writers have thrown light upon the relation between the acute infections and arterial disease. In 189 persons who had long recovered from enteric fever Thayer found that between the ages of 10 and 50 years 48 per cent. had palpable arteries, as compared with 17·5 per cent. in ordinary healthy individuals. Symnitzky in 138 necropsies on persons under the age of 25 years who died from various infections found sclerotic changes in the aortic wall in 38, or 27·5 per cent. Excluding subjects under the age of two years, in which these changes did not appear, they were found in 48 per cent. As to the etiology of the condition Professor Osler states: "That heredity plays a most important rôle is shown in the cases to which arterio-sclerosis sets in early in life in individuals in whom none of the recognised etiological factors can be found." Congenital syphilis is a well-recognised cause but its importance has been exaggerated by earlier writers who were not aware of the part played by acute infections. Hoffbauer, investigating nodular and diffuse arterio-sclerosis in the tuberculous, says that he "can find no pathological difference in the arterial wall between tuberculosis and nephritis" and that it will be necessary to give up the causal connexion between blood pressure and arterial thickening. Dr. Fremont-Smith has been able to collect from literature in all 146 cases of arterio-sclerosis in the young. These must represent but a small minority of the cases, for in few necropsies on children in Hornsey, 10·3 in Tottenham, and 10·8 in Leyton; the rates in the other towns ranged upwards to 24·3 in Devonport and in Rhondda, 24·7 in Middlesbrough, 25·0 in Merthyr Tydfil, and 25·6 in Oldham. The rate of mortality in London last week did not exceed 17·2 per 1000. The 5405 deaths in the 76 towns last week showed an increase of 148 upon the number returned in the previous week, and included 486 which were referred to the principal epidemic diseases, against 400 and 410 in the two preceding weeks; of these, 203 resulted from whooping-cough, 141 from measles, 52 from diphtheria, 38 from diarrhœa, 36 from scarlet fever, and 16 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·6 per 1000, against 1·3 in each of the three preceding weeks; the rate from the same diseases in London was equal to 1·7. No death from any of these epidemic diseases was registered last week in Tottenham, York, Ipswich, King's Norton, or in three other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 4·0 in Sunderland, 4·3 in Croydon, 5·2 in Salford, and 6·1 in Merthyr Tydfil. The fatal cases of whooping-cough in the 76 towns, which had been 134 and 152 in the two previous weeks, further rose to 203 in the week under notice; the highest death-rates from this disease last week in these towns were 2·0 in Sheffield and in Rhondda, 2·5 in Aston Manor, 3·3 in Sunderland, and 3·4 in Merthyr Tydfil. The 141 deaths from measles also showed a considerable increase upon recent weekly numbers, and caused death-rates equal to 2·0 in Burnley, 2·4 in Salford, 2·6 in Croydon, 2·7 in Preston, and 2·9 in Stockton-on-Tees. The deaths referred to diphtheria declined again, however, to 52 from 58 and 62 in the two preceding weeks; this disease, however, caused death-rates of 1·1 in Hornsey and 1·4 in Merthyr Tydfil. The 38 deaths attributed to diarrhœa corresponded with the number in the previous week. The 36 fatal cases of scarlet fever showed an increase of six upon those in the previous week, and included 15 in London, four in Liverpool, three in Manchester and Salford, and two in Newport (Mon). The 16 deaths referred to "fever" corresponded with the low number in the previous week; two were returned in London, in Nottingham, and in Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 16 preceding weeks from 5581 to 3356, had further fallen to 3229 on March 28th; 355 new cases were admitted to these hospitals during the week under notice, against 312 and 378 in the two preceding weeks. A case of small-pox (the first for many months) was admitted to the Metropolitan Asylums Hospitals during last week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 317 and 320 in the two previous weeks, further rose to 340 during the week under notice, and exceeded by 18 the corrected average number in the corresponding week of the five years 1903–07. The deaths directly referred to influenza in London, which had declined from 141 to 68 in the four preceding weeks, rose again to 71 in the week under notice. The causes of only 34, or 0·6 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified last week in Leeds, Bristol, Bradford, Newcastle-on-Tyne, and also in 54 other smaller towns; five uncertified causes of deaths were, however, registered last week in Birmingham, four in Leicester, and three each in Liverpool, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·3 and 18·5 per 1000 in the two preceding weeks, rose again to 19·4 in the week ending March 28th, and exceeded by 2·0 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rates last week ranged from 12·6 and 13·8 in Aberdeen and Greenock, to 21·7 in Glasgow and 26·9 in Dundee. The 683 deaths in these eight towns showed an increase of 31 upon the number returned in the previous week, and included 114 which were referred to the principal epidemic diseases, against 97 and 84 in the two preceding weeks; of these, 58 resulted from measles, 22 from whooping-cough, 21 from diarrhœa, seven from "fever," three from diphtheria, two from scarlet fever, and one from small-pox. These 114 deaths were equal to an annual rate of 3·2 per 1000, which was just double the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 47, 46, and 37 in the three preceding weeks, rose again last week to 58, and included 45 in Glasgow, six in Aberdeen, and four in Edinburgh. The 22 deaths from whooping-cough, however, were fewer by two than the number in the previous week; 13 occurred in Glasgow, four in Edinburgh, and two in Greenock. Of the 21 deaths attributed to diarrhœa, an increase of eight upon the number in the previous week, 12 were returned in Glasgow, and three in Dundee. The seven deaths referred to "fever," of which six were certified as cerebro-spinal meningitis and one as enteric, exceeded the low number in the previous week by four, and included four in Glasgow. Two of the three deaths from diphtheria last week were returned in Dundee, and the fatal case of small-pox was registered in Leith. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 142 and 158 in the two preceding weeks, declined to 133 in the week under notice, but exceeded by nine the number returned in the corresponding week of last year. The causes of 19, or 2·8 per cent., of the deaths in these eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 0·6 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·8 and 23·9 per 1000 in the two preceding weeks, rose again to 27·4 in the week ending March 28th. During the 13 weeks of last quarter the death-rate in the city averaged 25·5 per 1000, the mean rates during the same period being only 17·6 in London and 18·3 in Edinburgh. The 207 deaths of Dublin residents registered in the week under notice showed an increase of 26 upon the number returned in the previous week, and included but four which were referred to the principal epidemic diseases, corresponding with the low number returned in each of the two preceding weeks; these four deaths included three from whooping-cough and one from diarrhœa, whereas no death resulted from measles, scarlet fever, diphtheria, "fever," or small-pox. These four deaths from epidemic diseases were equal to an annual rate of but 0·5 per 1000, the death-rate last week from these principal epidemic diseases being equal to 1·7 in London and to 1·5 in Edinburgh. The fatal cases of whooping-cough in Dublin last week exceeded the numbers in recent weeks. The 207 deaths from all causes in the city last week included 29 of infants under one year of age and 68 of persons aged upwards of 60 years; the deaths of elderly persons showed a further increase upon recent weekly numbers. Three inquest cases and two deaths from violence were registered, and 77, or 37·2 per cent., of the deaths occurred in public institutions. The causes of ten, or 4·8 per cent., of the deaths registered during the week under notice were not certified; in London all but two of the 1581 causes of death were duly certified, and in Edinburgh the proportion of uncertified deaths was equal to 5·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: E. C. Cridland to the *Minotaur* on commissioning; and J. D. Hughes to the *Egmont* and for Malta Dockyard. Staff Surgeons: H. H. Gill to the *Terror*, additional; W. H. O. Garde to the *Emerald;* and J. A. L. Campbell to the *Donegal*. Surgeons: A. R. Davidson to the *Actæon;* and T. F. O'Keeffe to the *Minotaur* on commissioning.

ROYAL ARMY MEDICAL CORPS.

Captain A. F. Carlyon has been appointed for duty in the London District. Captain F. J. Turner has been transferred to Jubbulpore for duty.

IMPERIAL YEOMANRY.

Lincolnshire: Surgeon-Major Thomas H. Openshaw, C.M.G., to be Surgeon-Lieutenant-Colonel (dated Feb. 22nd, 1908.

the Baker-street bazaar owner's body had been burnt instead of buried.

THE annual discussion at the Hunterian Society will be held at the London Institution, Finsbury-circus, E.C., on Wednesday, April 8th, at 8.30 P.M. The subject selected this year is "Rheumatism." Dr. Frederick Taylor will open the discussion, Dr. F. J. Poynton and Dr. T. J. Horder will speak on the bacteriological aspects of the subject, while Dr. A. P. Luff will deal with irregular manifestations of rheumatism and their treatment. All members of the medical profession are invited to attend.

THERE was a large attendance at the Hospital Conference which we announced recently would take place this week at University College, London. The motion by the Hon. Sydney Holland in approval of a system of part payment by hospital patients in a certain pecuniary position was adopted, as was Colonel Montefiore's motion in favour of the general appointment of trained almoners. On Wednesday evening the members of the Conference dined together at the Waldorf Hotel under the chairmanship of Mr. Cosmo Bonsor.

Sir Felix Semon, K.C.V.O., M.D., has been appointed to represent the British Government at the International Laryngo-Rhinological Congress to be held at Vienna on the 21st of this month and following days.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

CORDINGLEY'S Thirteenth International Motor Car Exhibition was held last week at the Agricultural Hall, London. I must say that this show always attracted me, chiefly, I suppose, because at the exhibition some ten years ago my thoughts were first directed to automobilism, and since buying a car after the 1899 show I have used no other means of conveyance. This is the time of the year when those about to embark in and on a car begin to think of taking the plunge, and though many good makes were conspicuous by their absence there were some well worthy of consideration by the medical man in search of a car.

The Star Cycle Co., Limited, of Wolverhampton, had on Stand Nos. 111 and 112 specimens of their Royal and Imperial Starling Cars, all excellent machines for a medical man. The Imperial Starling has a single cylinder 8-h.p. engine, governed by variable inlet valves, the crank being of the built-up type with internal fly-wheels. The clutch is of the leather-faced cone type and of good dimensions, and with care should be neither too fierce nor, if kept properly adjusted, likely to slip. A gate change is fitted and three speeds forward and a reverse, the motion shafts running on ball bearings. The transmission is by cardan shaft to the now popular live axle. Two internal expanding brakes are fitted on the road wheels and a powerful foot brake works on the gear box shaft. A fan keeps the radiators cool and the water is circulated by a centrifugal pump driven by friction off the fly-wheel. This form of pump is similar to the one used on the old 7-h.p. Panard and I understand answers well, though personally I must say I prefer a gear driven pump. Ignition is by high tension coil and accumulators and the commutator is in an accessible position; magneto can, I understand, also be arranged for and for a medical man the double ignition is an advantage. The car is light, which means small tyre bills, and as a two-seater with a cape cart hood and a mica wind shield seems an ideal car for a professional man, the only alterations that I would suggest are a gear driven pump and extra high tension magneto ignition and, of course, the Stepney spare wheel—it is an advantage not to be delayed by a puncture. The Royal Starling is much the same, but has a two-cylinder engine of 10 h.p. and can be turned out with either a two- or four-seated body; the one shown with a four-seated body appealed to me as it was not too large for ordinary work and was also roomy enough for a tour with a couple of friends and baggage. Another advantage of these cars is that they are very simple and so in every way suitable for the owner who does not desire to employ a regular chauffeur.

Those in search of a larger and more powerful machine will perhaps fancy that shown by the Union Motor Car Company of Denbigh-street, London, who on Stand No. 89 had a fine specimen of Italian work in a 20-h.p. chassis, manufactured by the Societa Meccanica Bresciana, of Milan, which had four cylinders, variable lift to valves, Eiseman high tension magneto, automatic carburettor, single metal to metal clutch, positive lubrication by pump, four speeds and reverse with direct drive on top speed, gate control and cardan shaft transmission, with two universal joints. The metal expanding brakes have a neat compensating device, a differential gear in miniature making it impossible to apply the back brakes unequally. The makers seem to have a good opinion of their work, as a six years' guarantee is given against faulty material or workmanship. I do not know of any other manufacturer giving one covering such a long period.

The Reo Motors, Limited, of Broad Sanctuary, London, had on Stands Nos. 62 to 67 a fine collection of their cars ranging from 10 to 22 h.p. Their 10-h.p. single cylinder has a horizontal engine 4¾ by 6 inches, with transmission by a planetary gear giving two speeds forward and reverse, the drive being by single chain. Cooling is by a positive gear pump and the ignition is by accumulator and high tension coil, and at the price, £125 it certainly is worthy of consideration. It is true that horizontal engines are not fashionable, but the old Wolseleys had such engines and they did excellent work, and the fact that vertical engines are now so much in demand does not mean that they are the best.

An excellent four cylinder car is the Empress, exhibited on Stand No. 117 by the Empress Motor Company of Manchester. The cylinders are cast in pairs and the valves work in cast iron guides, while the pistons are of steel, which seems certainly a step in the right direction. Ignition is by low tension magneto in conjunction with a coil, so with an accumulator a double ignition is provided, which for a medical man is certainly an advantage. The clutch is of the internal type, faced with leather, and being mounted on the crank shaft is bound to remain always in alignment with the fly-wheel. The carburettor is the invention of the designer of the car and is so constructed that the motor is supplied with a constant mixture of petrol and air, irrespective of the speed of the motor, thus insuring great engine flexibility. Another low-priced four cylinder car well worthy of inspection is the F. N., shown by the F. N. Agency, of Great Portland-street, London. This is a Belgian car, built at Herstal, near Liège. The valves are all located on one side and operated off a single cam shaft; the crank, which runs in three long bearings, is slightly desaxe, cooling is by a centrifugal pump, and a fan is fitted behind the radiators. Lubrication is by positively driven pump. The clutch is of the friction-cone type and the male cone can be easily removed; it is connected by a flexible coupling to the change-speed gear, so the alignment of these parts is not affected by any movement or twisting of the frame. The transmission to the back axle is by a cardan shaft, having a universal joint at each end, and the joints are well protected from mud and dust. Ignition is by a high-tension magneto and the distributor is easily accessible, which is a great advantage.

Messrs. R. Reynold Jackson and Co., of Notting Hill-gate, London, had some light cars on view, of which the dog-cart and four-seated phaeton were most suitable for medical work. I understand that they will shortly introduce a special car for medical men with a De Dion engine. A body that was most beautifully upholstered was the "Sedan Chair," shown by the Metropolitan Garage Association of 12A, Palace-street, Westminster, London. The levers were all brought inside the carriage and the driver is absolutely protected, and if painted in a colour less easily soiled I cannot imagine a more comfortable or more suitable body.

A most useful device for motorists having a driver is the Donisthorpe Petrol Meter. It tells whether the driver is careful or wasteful with petrol, whether the car has been used for unauthorised trips, and whether the engine is working economically or not. It indicates precisely how much petrol is put into the tank, how much is used each mile of the journey, and how much remains at the journey's end. This meter, which is made by the Donisthorpe Patents Co. of 5, Southampton-street, Strand, London, can be quickly fitted and certainly is an advantage to owners who employ

TUBERCULOSIS AND THE MILK-SUPPLY.

To the Editor of THE LANCET.

SIR,—A conference was held at the Town Hall, Manchester, on Feb. 28th, of delegates representing the public health committees of the cities of Liverpool, Manchester, Birmingham, Leeds, and Sheffield in regard to the danger to man of milk containing the living infection of tuberculosis. Each of the above cities has had by reason of local Acts of Parliament considerable experience in the examination of samples of dairy milks for this infection. The result of this experience may be briefly stated by saying "*that the milk in about 10 per cent. of the churns sent into these towns contains the living infection of tuberculosis.*" From experience elsewhere it is almost certain that this high proportion is exceeded in many districts.

The report of the Royal Commission on Tuberculosis issued in January, 1907, states that "there can be no doubt that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there can also be no doubt that in the majority at least of these cases the bacillus is introduced through cows' milk. Cows' milk containing bovine tubercle bacilli is clearly a cause of tuberculosis and of fatal tuberculosis in man."

With this important statement, and the knowledge that in their own towns the amount of infected milk was large, the conference decided to approach the Government with a view to getting effective steps taken to eradicate bovine tuberculosis. The conference felt much strengthened in urging adequate preventive measures by the knowledge that any steps which will effectively deal with the tubercle-infected milk will at the same time benefit all consumers of milk in the direction of insuring a cleaner supply. And again, they feel that the direct benefit to farmers and butchers in preventing loss due either to the reduced value of the stock or to the seizure of tubercular meat intended for human food will be an important one. The conference passed the following resolution:—

> That having regard to the experience of the five towns whose delegates have conferred on this subject, and also to the return recently made to the House of Commons at the request of Dr. Rutherford, a representation be made to the Presidents of the Local Government Board and the Board of Agriculture and Fisheries with a view to inducing these Boards to take effective steps to enforce uniformly throughout the country proper and suitable inspection of dairies and cowsheds, and for regulating the construction of such dairies and cowsheds so as to insure cleanliness and suitable hygienic conditions; and further, that the Government be respectfully asked to include in their prospective legislation dealing with milk, clauses calculated to bring about the eradication of tuberculosis from bovines within a measurable period of years.

It is intended to present this resolution to both the Local Government Board and the Board of Agriculture.

I am, Sir, yours faithfully,
THOMAS FLETCHER,
Chairman of the Conference and Chairman of the
Health Committee of the Corporation
of Birmingham.

The Council House, Birmingham, March 21st, 1908.

CALMETTE'S TUBERCULIN TEST IN 210 ASYLUM PATIENTS.

To the Editor of THE LANCET.

SIR,—I have recently applied the Calmette test to 210 patients in this asylum. After reading the many papers on the subject I took the reliability of the test for granted and undertook its application with a view to ascertaining the proportion of tubercular cases here, influenced as I was by the proposed building of a verandah for such patients and the question of the necessary amount of accommodation to be provided. In performing the test I left out every patient where struggles or excitement was likely to interfere with the proper application of the tuberculin to the eye. I selected only those whose eyes were healthy. The 210 patients constituted 80 per cent. of the total paupers resident. At the time there was only one case of active phthisis. This girl, tested with a solution of 1 in 150, gave the reaction in three hours. There were also four cases where the patients had during the past two years suffered from active pulmonary tuberculosis, but all were in a quiescent state and in good condition after prolonged open-air treatment. All four reacted to a 1 in 150 solution. Of the others 91 patients gave a positive reaction. Many of these were undoubtedly of poor nutrition but none of them as yet have furnished any other proofs of tubercle.

One hundred cases were tested with the 1 in 150 solution, the remaining 110 with solutions varying in strength from 1 in 300 to 1 in 700. Taken in batches of 25 for each particular solution it was found that there was a slightly reduced proportion of positive reactions as the solution was weakened. In the batch tested with 1 in 700 there were six positive reactions; two of these in very healthy persons were the most violent reactions of all the cases. If the test be reliable it cannot anywhere be of such service as in an asylum where the symptoms of tubercle like those of other diseases are often more obscure than usual and where early separation of the affected cases is so desirable. This asylum has had for years the reputation of being singularly free from tubercle, though in the past year the death-rate from phthisis has gone up, but a proportion of nearly 50 per cent. of positive reactions to the Calmette test suggests either a serious condition of affairs here or a want of reliability in the test. It would be rash in view of other experiments performed by specialists to accept the latter theory and so it seems to me that it is not verandahs or sanatoria for consumptive patients alone that we so much need as a general extension of the system of open-air treatment of all the insane.

I am, Sir, yours faithfully,
JAMES P. STURROCK, M.A. St. And., M.D. Edin.

Midlothian and Peebles Asylum.

A DIAGNOSTIC SIGN OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—Since the reappearance of influenza in 1889 I have attended many thousands of cases and for several years have noticed that in every case there is present a swelling or œdema of the uvula. This swelling gives the uvula a pale, waxy, œdematous appearance. It is found at the commencement of the attack and usually lasts for several days. It is often present before there is any rise of temperature and remains after the temperature has fallen to normal. It is therefore useful in diagnosing very early cases and also those seen after the acute symptoms have passed off. I believe this œdema of the uvula is a certain sign of influenza. The present epidemic will give many medical men an opportunity of observing this sign.

I am, Sir, yours faithfully,
W. GIFFORD NASH.

Bedford, March 28th, 1908.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—I have to sincerely thank you for the patient and impartial hearing you have given me on the above matter and, if I am not mistaken, *time will show* that there are a great many besides myself—general practitioners, "specialists," and public—who will also have reason to be grateful to you. If Dr. Saundby will refer to my letter of March 14th ult. he will see that I specifically mentioned that "the patient or the patient's friends must needs agree" to my proposal: that *one-third* of an upset fee for surgical (or special medical) treatment and after-attendance with assistance at operation be paid "on the nail" to the family practitioner and two-thirds to the so-called "specialist," the fees of either practitioner ranking equally as when and how paid or payable in due proportion. Dr. Saundby has no doubt misunderstood me and as a consequence has misrepresented me, so that his "slight modification" was quite unnecessary.

The main point is, that my proposal is, according to Dr. Saundby, late President of the British Medical Association, chairman of its ethical committee, member of the General Medical Council, and an acknowledged author of a valuable work on ethics, "*a perfectly honest and fair transaction.*" That is my point fully conceded and the rest does not now matter.

What is to be expected from this important reform in medico-chirurgical tariff? (*a*) It will be a powerful lever in stopping hospital abuse; (*b*) it will meet the pockets of patients whose resources are slender, but who desire to pay for what they get in proportion; (*c*) it places the interests of the general practitioner and "specialist" on an equal drowsiness and contraction of the pupils which he observed were due to the opium in his son's medicine. On the following morning Mr. F. H. Fawcett was called in. According to his evidence he found the patient comatose, with pin-point pupils, a temperature of 96° F., and stertorous breathing. He found traces of albumin in the urine but did not consider that there were indications of the kidneys being affected sufficiently to account for the state in which the man then was or to account for his death which took place that night. Dr. G. C. Low, pathologist at the West London Hospital, who had held a post-mortem examination by order of the coroner, gave evidence that he had found no disease except that the heart was flabby with thin walls; the lungs had spots of tubercle, and the substance of the kidneys was slightly fatty but there was no Bright's disease. He was of opinion that the diarrhœa was not of a typhoid but of a tuberculous nature, and that there was no disease to account for the death which, he had no doubt, was due to opium poisoning. After a prolonged inquiry the jury found a verdict of "Opium poisoning due to misadventure," adding a rider by which they requested the coroner "to caution severely the druggist against prescribing medicine indiscriminately and especially for giving poison without caution." The druggist had given evidence after being informed by the coroner that in the circumstances he need not do so. He took up the position that he did not transgress the law in handing to the woman a medicine for diarrhœa when she asked for one but that he would have done wrong if he had examined the patient or had joined in a consultation with regard to him, and he considered that what he had done did not amount to making a diagnosis. With regard to the question of selling a poison without so describing it on the label, he relied on the exemption in the Pharmacy Act, 1868, Section 17, applying to poisons forming part of "ingredients dispensed by a person registered" under the Act. It was then pointed out to him that even if this application of the term "dispensing" were correct, the exemption only applied when medicine was dispensed under conditions which included the entry of the ingredients in a book with the name of the person to whom it was sold, and he admitted that he had made no such entry. For this omission he had no explanation except that it was an error. Discussion took place with regard to the terms of the Apothecaries Act and the Pharmacy Act so far as they might apply to conduct such as that admitted by Mr. Thomson, and it was shown that they were not susceptible of easy interpretation. The coroner, in summing up to the jury, laid stress upon the gravity of the position in which Mr. Thomson had placed himself by what he had done. He was not, however, of the opinion that his conduct amounted to criminal negligence such as would involve the charge of manslaughter, but rather to recklessness to be met by such censure as the jury afterwards found to be due. It will be enough to add that in the interests of the public, of the medical profession, and of the druggists the position of the last named should be more strictly defined, and that their responsibility in attempting to treat disease should be made so clear that any approach to doing so would be avoided by them.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions should have been included in the first list of contributions to this fund which was published in THE LANCET last week:—

Subscribers of One Guinea.

C. R. Graham, Wigan.
G. J. W. Pluching, Gravesend.
W. E. Thomas, Bridgend.
H. Egerton Williams, Newport, Mon.

A second list of subscriptions has now been sent to us by Mr. William Sheen and includes support which he has received between March 21st and 28th:—

Subscribers of Five Guineas.

Plymouth Medical Society, per J. Elliot Square.
Woolwich, Plumstead, and Charlton Medical Union, per E. Atkins.

Subscribers of Two Guineas.

Sir John Broadbent, Bart., London.
T. M. Butler, Guildford.
Philip Frank, London.
W. W. Leigh, Treharris, Glam.
Grantham Medical Society, per J. W. Hancock Stell.
J. Crawford Renton, Glasgow.
T. J. Walker, Cambridge.

Subscribers of Two Pounds.

South Essex Division, British Medical Association, per W. Cardy Black.
W. Domett Stone, London.

Subscribers of One Guinea.

W. F. Addey, Croydon.
H. A. Ballance, Norwich.
Arthur Bevan, London.
G. Buckston Browne, London.
W. S. Carroll, Pontypridd.
W. A. Collins, Bexley.
W. Cotton, Bristol.
C. J. Cullingworth, London.
C. A. Ensor, Tisbury, Wilts.
Frederick Eve, London.
L. G. Glover, London.
Geo. Govan, Cockermouth.
J. A. Hall, Huddersfield.
P. S. Hichens, Northampton.
A. H. W. Hunt, Wolverhampton.
F. H. Jacob, Nottingham.
Hugh Lett, London.
H. R. Campbell Litchfield, Twickenham.
E. Muirhead Little, London.
T. R. Llewellyn, Penygraig, Glam.
F. Manser, Tunbridge Wells.
John Marnoch, Aberdeen.
Andrew McFarland, Aylesbury.
L. M. McIntosh, Blackpool.
Norman Porritt, Huddersfield.
J. G. Rowell, Huddersfield.
R. P. Rowlands, London.
S. H. Sharpe, Goring-on-Thames.
G. C. Sprawson, Blackpool.
Edward Turner, London.
Dawson Williams, London.
John H. Wood, Hereford.
R. J. Worger and J. Pratt, Radstock, Bath.

Subscribers of One Pound.

G. Leonard Brown, Pau, France.
N. H. Harris, Surgeon, R.N.

Subscribers of Half a Guinea.

C. S. Bowker, Pontnewydd, Mon.
John Brown, Bacup.
C. W. Cathcart, Edinburgh.
J. Charles, Stanley, Durham.
A. J. Couzens, London.
E. Hooper May, London.
F. J. Nicholls, Eltham, Kent.
A. G. Osborn, Dover.
W. P. Purvis, Southampton.
M. K. Robinson, Dover.
A. Scot-Skirving, Edinburgh.
A. C. Wood, Nuneaton.
M. A. Wood, Ledbury.

Subscribers of Five Shillings.

B. Jex Blake, Hereford.
H. Leak, Winsford, Cheshire.

Erratum.—The name of J. B. Footner, Tunbridge Wells, was wrongly included among those of subscribers of one guinea last week. It should have been inserted in the two-guinea section of subscriptions.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 3rd, 1830.

ACTION OF ASPARAGUS[1] ON THE CIRCULATION.—Digitalis and prussic acid possess the property of weakening the action of the heart, but the employment of these medicines is frequently prevented by the gastric irritation they produce. M. Broussais proposes, as a substitute for these remedies, asparagus, which is perfectly inoffensive to the stomach, and acts as a sedative upon the heart. If a patient, who is suffering from hypertrophy and excessive action of the heart, eat asparagus, M. Broussais assures us he will find relief; and if the remedy be discontinued, the habitual symptoms will return. Syrup of the green ends of asparagus, like the plant itself, has the power of diminishing the action of the heart, without annoying the stomach. A man, having hypertrophy of the heart, perceived a very decided alleviation of his sufferings while he was in the habit of eating asparagus, and he consequently prepared a syrup of the plant for use when it was out of season. A physician whom M. Broussais does not name, but to whom he is indebted for this discovery, collected many cases in support of this statement; and the Professor of Val-de-Grâce declares that it is confirmed by the result of his own experience.—*Ann. de la Méd. Phys.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8583 births and 5405 deaths were registered during the week ending March 28th. The mean annual rate of mortality in these towns, which had been equal to 17·6, 17·2, and 16·9 per 1000 in the three preceding weeks, rose again to 17·4 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged 18·0 per 1000; the mean rate in London during the same period did not exceed 17·6. The lowest annual death-rates in the 76 towns last week were 9·5 in East Ham, 9·6 children it is quite as important that the parents should be in the finest physical condition and they should therefore be carefully selected so that the stud farm might show satisfactory results. An era of perfection has not yet arrived and may possibly not be hastened by the best intentioned panaceas, so that for the present we must go on doing what can be done by individual effort, by individual help such as is given by the Ladies' Sanitary Association, and by the cultivation of sincerely friendly relations between the various sections of the people. In regard to all these matters it is to be hoped that after the throes and strife of the present educational turmoil a more practical, more impressively moral, and less lifeless, machine-made education may be evolved.

---

[1] It may be interesting in conjunction with the above to recall an annotation entitled "Is Asparagus Wholesome?" which appeared in THE LANCET of May 19th, 1906, p. 1405.

The late William Walter, M.A., M.D. Dub., F.R.C.S. Irel.

Manchester has sustained a serious loss by the death of Dr. William Walter who for many years had stood in the front rank of the local medical profession. He was honorary surgeon to St. Mary's Hospital and to the Manchester and Salford Lying-in Hospital, and contributed many papers to the medical journals on gynæcological subjects. His body was cremated at the Manchester crematorium on March 20th. In addition to the widow and sister there were many private mourners and a large attendance of medical and other friends, some of whom represented the Medical Society of Manchester, the Clinical Society, the South Manchester Division of the British Medical Association, and other societies.

Ink Applied to Scalds.

A child, three years old, was playing in the kitchen on March 25th, when, as small children are prone to do, he pulled over a vessel of scalding hot coffee. His back was severely scalded and he died in the Manchester Royal Infirmary on the next morning. When the child arrived at the infirmary his back was covered with ink. The father said that he thought the ink would do the scalds good. The coroner remarked that it was the most weird thing he had ever heard of to put ink on wounds received by scalding and the foreman of the jury added that it was a most ridiculous thing to do. With these opinions many will agree.

March 31st.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondent.)

The Notification of Pulmonary Tuberculosis.

A conference was recently held at Merthyr Tydvil on the initiation of the board of guardians to consider the desirability of making pulmonary tuberculosis compulsorily notifiable within the Merthyr Tydvil union. Those who took part in the conference represented the corporation of Merthyr Tydvil and the district councils of Aberdare, Gelligaer, and Rhigos, and Vaynor and Penderyn. Mr. J. L. W. Ward, the medical officer to the workhouse, said that compulsory notification would enable the sanitary authorities to advise those responsible for the care of patients as to the necessity for isolation and in other ways to prevent the spread of the disease. Dr. A. Duncan, the medical officer of health of Merthyr Tydvil, was of opinion that notification by itself would be of little advantage. He thought that the boards of guardians might do more than they do at present for the family of a worker when the latter was undergoing treatment and spoke with approval of the establishment of a special dispensary where curable cases could be discovered and sent for treatment to a suitable institution. Ultimately a resolution was carried approving of the principle of compulsory notification of the disease.

A Combined Sanitary District in Monmouthshire.

One of the results of the inspections of the colliery districts in the Western valleys of Monmouthshire during the past few years by medical inspectors of the Local Government Board has been a very strong recommendation by the Board to two district councils to appoint a whole-time medical officer of health to act jointly for certain adjacent districts. All the councils concerned have been very much opposed to this recommendation, but at a meeting recently held between delegates from the authorities and the medical officers of the Board the latter emphasised the advantages that would arise from the formation of a combined district and it is probable that one will now be made.

Exhibition of Week-end Cottages at Malvern.

In very many schemes for the provision of houses for the working classes it has too often happened that the dwellings when erected have not been occupied by the class of persons for whom they were intended. Rows of low-rented cottages have been tenanted by well-paid artisans and detached dwellings in garden cities have been utilised as week-end cottages by the well-to-do. The promoters of an exhibition of small houses to be erected on the western slope of the Malvern Hills state quite frankly that they do not desire the erection of houses for the working classes but small inexpensive dwellings suitable for the requirements of a better class of tenants. Prizes will be given for the best and second best of three different types of dwellings: one to contain at least four bedrooms and to be either detached or semi-detached, to cost between £300 and £500; a second to be in the form of a detached bungalow and to contain at least six bedrooms, to cost from £500 to £800; and a third of a more pretentious character to contain eight bedrooms and to cost between £800 and £1200. The land which is set apart for the proposed buildings will be let for the first year at a peppercorn rent and subsequently either leased or sold outright. The capital cost of the land will range, it is said, from £100 to £300, according to the amount and position of the plot. The parish of Colwall in which the houses will be erected is one of the healthiest parts of Herefordshire. The death-rate, according to the recently issued report of the medical officer of health, was in 1907 only 5·6 per 1000 and the average rate in the past seven years was 8·5 per 1000. Under the terms of a recent Act of Parliament the district is supplied with water from the mains of the Malvern urban district council.

March 31st.

SCOTLAND.

(From our own Correspondents.)

The Medical Education of Women in Edinburgh.

The close of the winter session in Edinburgh has been signalised by a considerable amount of excitement and activity on the part of a section of those who are interested in the medical education of women in Edinburgh. To understand the position aright it is necessary to recall the steps which have led up to the present. The establishment of a medical school for women in Edinburgh was due to the energy and resourcefulness of Dr. Jex-Blake. The school which she established was not long in existence when a split occurred which led to an action at law and the starting of an opposition school. The schismatics, if the word can be used without offence, got a certain measure of public sympathy and support and an association was formed called the Scottish Association for the Medical Education of Women. A board of lecturers was appointed from the junior members of the extramural school. The association consisted of (1) persons who contributed a small sum per annum to the association; (2) the lecturers who were to pay to the association a percentage of their class fees; and (3) the students who were to pay a matriculation fee to the association. These contributions were required to meet the expenses incurred in the form of rent for premises and a lady secretary's salary, &c. A number of persons were appointed as the court of the association with a president to preside over its deliberations. The members of the court were to be appointed, so many by (1) the members of the association, including contributors to its funds, lecturers, and students; (2) by the lecturers; and (3) by the students. At first the number of students was very small, five or six, perhaps; humble but efficient accommodation was obtained in Chambers-street, including an office and a dissecting room. Some of the lectures were given in these rooms, others were given elsewhere, according to whether the lecturer had his rooms elsewhere or not. At that time women were not admitted to the degree in medicine but were admitted to the double or triple qualification given by the licensing bodies. Owing to changes in the extramural school the anatomy room and some other rooms at Minto House, Chambers-street, became available and the association rented them for the use of its students and transferred the secretary's office to them. The University, after considerable agitation, opened its degree to women and accepted the classes supplied by the Scottish

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Hampshire: Percy James Sandys Bird (late Surgeon-Captain, 1st West Riding of Yorkshire Royal Garrison Artillery (Volunteers)), to be Second Lieutenant (dated Feb. 1st, 1908). 1st Northumberland: Surgeon-Captain (Honorary Captain in the Army) John Wreford to be Surgeon-Major (dated Jan. 21st, 1908).

Rifle: 3rd Volunteer Battalion, The Northumberland Fusiliers: Surgeon-Lieutenant Herbert M. Jamieson resigns his commission (dated Feb. 29th, 1908). 5th (Irish) Volunteer Battalion, The King's (Liverpool Regiment): Surgeon-Captain John J. O'Hagan to be Surgeon-Major (dated Feb. 25th, 1908). 1st Volunteer Battalion, The Hampshire Regiment: Surgeon-Lieutenant Herbert J. Godwin to be Surgeon-Captain, remaining supernumerary (dated Feb. 22nd, 1908). 2nd Volunteer Battalion, The Hampshire Regiment: Surgeon-Lieutenant Robert E. Lauder to be Surgeon-Captain (dated Feb. 7th, 1908). 3rd Volunteer Battalion, The Essex Regiment: Surgeon-Captain Francis J. Warwick to be Surgeon-Major (dated Feb. 26th, 1908). 3rd Volunteer Battalion, The Queen's Own (Royal West Kent Regiment): Surgeon-Captain Lewis T. F. Bryett to be Surgeon-Major (dated Jan. 21st, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Liverpool Bearer Company: Captain Samuel H. House resigns his commission (dated March 31st, 1908).

DEATHS IN THE SERVICES.

At Wellington, Somerset, on March 24th, Colonel Joseph Henry Moore, R.A.M.C. (retired), in his sixty-fourth year. The deceased had been for 30 years in the service. He was in the Ashanti War, 1873–74, being at the defence of the hospital at Foomana (medal and clasp). In the Afghan War, 1878–79, Colonel Moore was present at the occupation of Candahar, the battle of Khelat, the Ghilzai actions, and also at Ahmed Khel and Urzoo (mentioned in despatches, medal, and clasp). Subsequently Colonel Moore served in India and was principal medical officer both at Quetta and Bombay.

Surgeon-Major-General Thomas William Fox, A.M.S., on March 28th at his residence at Rochester. He joined the service as assistant surgeon in 1852, became surgeon in 1860, surgeon-major in 1872, deputy surgeon-general in 1880, and surgeon-major-general in 1887. He retired in the following year. He served with the 14th Light Dragoons in the Persian campaign of 1857 and was present at the bombardment of Mohumrah (medal with clasp).

OUTBREAK OF DIPHTHERIA ON H.M.S. "IMPREGNABLE."

It has just been officially notified that owing to the number of cases of diphtheria on board the *Impregnable* (the boys' training establishment at Devonport) the ship has been placed under sanitary regulations. For some time there have been an unusual number of cases of illness and over 100 boys have been removed to the Royal Naval Hospital, Stonehouse, including 24 suffering from diphtheria. There are now about 700 boys and instructors on board.

RECRUITS AND BAD TEETH.

At a meeting of the Royal Dental Hospital held on March 26th the Hon. W. F. D. Smith, M.P., who presided, called attention to the large number of recruits for the army who were rejected owing to their teeth being too bad to eat army food.

Colonel Valentine Matthews, late commanding London Companies Royal Army Medical Corps (Volunteers), has been appointed an honorary officer (1er Jefe Honorario) of Ambulancia No. 3 (Madrid), Spanish Red Cross.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—The annual general meeting of the Medical Graduates' College and Polyclinic was held at 22, Chenies-street, London, on March 27th, Dr. C. Theodore Williams being in the chair. The annual report, which was duly adopted, gave an interesting account of the success and the progress of the institution, the total number of attendances of medical men at the lectures and cliniques making a grand total of 13,852. The courses of instruction in opsonins and vaccine therapy had attracted a great many practitioners, and the clinical investigations conducted by Captain A. E. H. Pinch, I.M.S. (retired), the medical superintendent, had proved as profitable as they were successful.

Correspondence.

"Audi alteram partem."

"AUDI ALTERAM PARTEM."

To the Editor of THE LANCET.

SIR,—Many members of our profession have noticed with regret a statement that Mr. Edge, a judge in the Clerkenwell county court, has seen fit to criticise in very forcible language the conduct of a much respected medical practitioner. In the case of Cropper *v.* Stokes it was asserted by the plaintiff that Dr. Henry Fraser Stokes of Highbury had agreed to attend a patient at Horsham, that he stated his fee to be 5 guineas per visit, that he agreed to reduce this fee to 3 guineas (the charge per visit made for a previous attendance at Oxted, a much nearer point), that he subsequently demanded a cheque in payment on the 5-guinea basis, promising to refund £17, which would practically restore the 3-guinea scale, and that he did not make restitution as promised. Medical men will at once recognise that such an arrangement as this would be unique in the annals of practice and that improbability—nay, impossibility—is stamped on the face of it. Its existence was absolutely denied by the defendant. On the side of the plaintiff there were three witnesses. Dr. Stokes himself gave evidence for the defence. The judge appears to have had no difficulty in believing the stronger seeming side, and incidentally he is reported to have accused Dr. Stokes of perjury and that in terms which were not distinguished by moderation. To those who know Dr. Stokes its mere association with him is incredible. Mr. Edge is said to have based his decision and his strictures on the facts that the plaintiff was supported by several sworn witnesses and that these were corroborated by correspondence.

Under all the circumstances, Sir, I feel sure that your readers will be interested in hearing the other side of this singular case. In the first place, the "correspondence" referred to, which seems to have brought such weighty consequences in its train, was on one side only, like the bulk of the evidence—namely, on that of the plaintiff. No letter came from Dr. Stokes. Further, the assertion that fees once fixed at 5 guineas had been reduced to 3 guineas is without foundation. There is, indeed, no reason for such a reduction but every reason to the contrary.

Horsham is 39 miles from London, Oxted but 20, and the assumption that both places could be set on an equality of remuneration will commend itself to no sane man acquainted with medical procedure. Finally, the alleged engagement to receive a cheque and to refund a portion of it is, as every practitioner would suppose, entirely imaginary. It may have arisen, as has been suggested, by what process of logic I cannot conjecture, from a statement by Dr. Stokes that in the event of poverty on the plaintiff's part being shown he might consider some reduction of the amount due to him; in fact, from the sort of optional and provisional concession which medical men are making every day and which in future they are likely to make with greater caution than hitherto, if at all.

Such is the case and such the conditions of judgment which have given rise to the most emphatic reprobation of a universally respected and estimable practitioner engaged in simply maintaining his right to adequate remuneration. With Mr. Edge's position as a judge in dealing with a numerical balance of evidence or in sifting its purity I do not concern myself but certain points about this case must, I think, stand out in relief. These are the mainly one-sided character of the evidence, the imputation of perjury without any demonstrated proof, the violence of denunciation which attended this, and, lastly, the harshness which denied an appeal against a judgment with these aggressive accompaniments. It is possible that on reflection Mr. Edge himself regrets the freedom of his remarks and, if so, he cannot as a gentleman do less than state the fact. As for Dr. Stokes, he may rest assured that whatever the temporary discomfort of his present position he cannot forfeit the esteem of his medical brethren.

I am, Sir, yours faithfully,

Green-lanes, N., March 31st, 1908. B. G. MORISON.

Barnhill Poorhouse, 2542 patients; or, in all, 5104 patients. The cost of indoor medical relief for last year was £6556 at Stobhill Hospital, £2562 at the Eastern Hospital, £1916 at the Western Hospital, and £1795 at Barnhill Poorhouse. The medical cost of each patient in the various hospitals thus varies from 1*s.* 5*d.* to 3*s.* 11¾*d.* per week.

Cancer Hospital, Glasgow.

Glasgow will soon be furnished with a perfectly equipped Cancer Hospital in Garnethill, where large extensions to the old building are at present in progress. These extensions are estimated to cost £21,550 and towards this the directors have already in hand £17,980, including the sum of £1500 given by the corporation.

Frozen Boneless Meat.

The veterinary surgeon of the corporation of Glasgow has been asked to report on the regulations which in his opinion should be issued under the powers of the Public Health (Regulations as to Food) Act, 1907, in regard to frozen meat. In his opinion all meat imported from over seas ought to be presented for examination in such a form as to enable the inspectors here to revise the work of inspection at the place of slaughter. To enable this supervision to be exercised he suggests that all meat should be presented for examination as follows: beef, either in sides or quarters; mutton, lamb, and veal in carcasses; and pork in sides. Were such regulations to be enforced all boneless meat or scrap would be entirely excluded. He suggests that stripping or tampering in any way with the serous membranes should be prohibited and certain groups of the lymphatic glands ought to be mentioned specifically as requiring to be retained *in situ*. Provision should also be made that all pork imported into the country is examined microscopically for trichina spiralis. All preservatives other than common salt ought to be prohibited. In order to facilitate such work of inspection all imported meat ought only to be permitted to enter the country through certain specified ports. In that case it is suggested that the inspection staffs should be appointed and paid by Government and not by the local authorities.

The Glasgow Royal Infirmary Club.

Although for many years the past and present residents of the Glasgow Royal Infirmary have had an annual dinner it was only last year that as a result of these meetings the "Glasgow Royal Infirmary Club" was formed. The first annual dinner of the club was held in the Grosvenor Restaurant last week, Dr. John Aikman of Guernsey being in the chair. There was a large attendance of past and present residents and a very enjoyable evening was spent. The committee of the club is preparing for publication a list of all past residents from the opening of the infirmary in 1795. The list is particularly interesting in showing the great development of the work done since that time. In 1796 there was only one physician's clerk. In 1798 a surgeon's clerk was appointed but he also officiated as apothecary and in some years as chaplain in addition. Now there are 15 resident assistants. In preparing the list there has been some difficulty in obtaining addresses for the names on the roll and it is hoped that all past residents who have not received notice of the dinner will communicate with the secretary, Dr. James Scott, 103, Hyndland-road, Glasgow, and will give what information they can concerning the men of their time. The subscription for the life membership of the club is 10*s.* 6*d.* and it has been arranged that the annual dinner will in future be held on the second Friday in March.

March 31st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University Bill for Ireland.

Mr. Birrell's University Bill for Ireland, considering the grievous nature of the difficulties presented by the question and the long-standing of those difficulties, has been received by the country concerned with a good deal of the pleasure that it deserves. Absolute satisfaction was not to be hoped for, and the criticisms both of Belfast and the Royal College of Surgeons in Ireland were anticipated and to some extent are reasonable. But the general feeling appears to be that the passing of this Bill will give a vast impetus to professional education in Ireland, a consummation which all medical men must devoutly desire.

Emigration from Ireland.

In 1907 the total number of emigrants who left Ireland was 39,562, an increase of 3644 as compared with 1906. Of these emigrants the males exceeded the females by 3000, and it is deplorable to find that 84 per cent. of all the people who left Ireland in 1907 were between the ages of 15 and 35 years, while it is noteworthy that the age period of between 20 and 25 years furnished the largest numbers of both males and females, showing that young men and women in their prime who ought if possible to be retained in the country are leaving it, to the great loss and injury of the country. The only one of the four provinces that did not show an increase in the number of its emigrants last year was Connaught, in which a decrease of 310 was reported.

The Recorder of Dublin on Crime and Insanitation.

The Recorder of Dublin took the opportunity, in opening the business of the city criminal sessions on March 26th, to refer at some length to one of the most important questions now engaging the public attention of our citizens—the housing of the poor and the connexion of the same with public health and with public morality and political justice. After congratulating the grand jury on the comparative freedom of their city from the graver classes of crime, in which it compares so favourably with many or most of the other large cities of the Empire, the Recorder passed to a consideration of the housing of the working classes. The transition exposed the contrasted conditions: while the slums of Dublin are conspicuously free from the worst forms of crime their physical conditions present a bad pre-eminence. The Recorder declared, as so many have declared before him, that the wretched dwellings of the poor were "largely the source of the drink evil, most certainly the source of the disease, and in many respects the cause of the crime, such as it is, which prevails in the city." He continued: "I cannot conceive the existence of the present condition of the houses of the working classes except upon the supposition of the long subordination of the interests of the poor and humble to vested interests in their disease, misery, and vice. I trust that some measure will be found to enable this eating canker in our midst to be eradicated. It affects the physical and moral well-being not only of our poorer citizens but of every inhabitant of the city." The truth of these remarks is well known to every observant citizen, and the one encouraging feature connected with their enunciation is that coming from such a source they are sure to receive a great deal of attention. In Dublin 24,000 families are living in single rooms, and it is to the effects of this appalling prevalence of the *tenement room* residence of so large a proportion of the families of the whole population of the city that the proverbially high mortality of the Irish metropolis is really due.

Election of Professor of Medical Jurisprudence and Hygiene in the Catholic University, Dublin.

The vacancy in the professorship of medical jurisprudence and hygiene, which was recently created by the sudden death of Professor Antony Roche, was filled on March 27th by the election of Professor E. J. McWeeney who already occupies the chair of bacteriology in the Catholic University. The reputation of the new occupant of the chair has been so well established for a considerable number of years in the science of bacteriology and in the various domains connected therewith, that no surprise was expressed at the double nature of the duties which he will now discharge in the teaching staff of an important and growing medical school. The wide range of Professor McWeeney's attainments have always been highly appreciated by his pupils and his colleagues; while in the pathological section of the Royal Academy of Medicine in Ireland—of which he is an ex-President—his communications have always been heard with great interest. He is also bacteriologist to the Local Government Board in Ireland; and his contributions to such periodicals as the Journal of the Department of Agriculture, the Journal of the Royal Agricultural Society of England, the Proceedings of the Statistical Society of Ireland, and the Proceedings of the Royal Dublin Society are always characterised by their practical utility.

Royal Victoria Hospital, Belfast.

At the 115th annual meeting of the corporation of the Royal Victoria Hospital, Belfast, held in that institution on March 23rd, it was reported that during the past year there had been 3080 new intern patients, which with the 201 remaining over from the previous year, made a total of 3281 cases treated in the wards during the twelve months of footing; (*d*) it insures the practitioner retaining his patient as his own; (*e*) the interests of patient, family practitioner, and "specialist" are now co-extensive, co-equal, and identical; (*f*) a fair chance in life is given to the younger and lesser lights amongst the "specialists"; and (*g*) the amenities of honourable and amicable dealing between the two grades of practitioners will be assured. And all this by a proposal which has been pronounced "*a perfectly honest and fair transaction*" in THE LANCET.

I am, Sir, yours faithfully,
F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng.
Harley-street, W., March 30th, 1908.

DEATHS DURING ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Certain reports which have recently appeared in the lay press seem to render it desirable that I should make my position with regard to the agitation now proceeding quite clear. 1. I maintain that a certain number of deaths from anæsthetics is inevitable. 2. In the majority of cases referred to by the coroners the primary cause of death was the nature of the accident or disease from which the patient was suffering and only very remotely the anæsthetic. 3. That even if one accepts the coroner's figures, they afford no justification for alarming the public in the way which is being done, either in themselves or in comparison with the enormous number of operations which are now performed. 4. All who administer anæsthetics are, I am sure, very willing that full inquiry should be made into their methods and results; but I, at any rate, firmly maintain that a coroner's court is not the proper place where, nor are the coroner and his jury the proper people by whom, such inquiry should be conducted. 5. Inasmuch as the tendency to a fatal result is to some extent influenced by the mental attitude of the patient, appeal is made to the coroners to assist in keeping out of the lay press all sensational reports and misleading statements which might tend to create a condition of panic in the public mind.

I am, Sir, yours faithfully,
J. FREDK. W. SILK.
Devonshire-street, W., March 31st, 1908.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Inspection of Children in Birmingham.

THE education committee recently discussed and adopted the report of the elementary education subcommittee upon the medical inspection of school children. The subcommittee recommended that for the purposes of the inspection three medical practitioners and three women attendants should be appointed. The practitioners are to be appointed for one year, with eligibility for reappointment for a second and a third year, and the salary offered is £250 per annum. The salary of each woman attendant is to be £50 per year. The subcommittee further recommended that the present medical superintendent should be converted into the medical officer to the education committee, who should be held responsible for the whole work of inspection and the recording of the results obtained. It is scarcely probable that under the terms of the appointment any but comparatively inexperienced practitioners will be secured for the work of inspection, and it may be questioned whether they will be able to make an examination giving results of any great value in the ten minutes which is the time given as that probably required for each examination. It is estimated that the cost of the scheme will be £1500 per year but there can be no doubt that this sum will be considerably exceeded in the future. The scheme has yet to go before the council and it may meet with considerable opposition.

Food Poisoning.

At a recent meeting of the Midland branch of the Incorporated Society of Medical Officers of Health held in Birmingham there was an interesting discussion upon the subject of food poisoning. We are all familiar with the fact that bacteria may produce poisons in the foods which we eat or they may be introduced into our bodies with the food and act directly upon us. It is perfectly true, as Dr. R. A. Lyster pointed out, that with regard to ptomaines or to the direct action of bacteria there are personal idiosyncrasies and some of us may be immune to many potent organisms or poisons, but we cannot depend upon that immunity, consequently we are all anxious to know exactly where the danger lies and how it is to be avoided. Upon this point, however, the discussion threw no very clear light. Dr. A. Bostock Hill and Dr. H. Malet are impressed with the danger of leaving flesh intended for food in slaughter-houses and they would guard us by insisting upon the entire separation of slaughter-houses from the places in which food is further prepared for consumption. Dr. Robertson and Dr. Lyster appeared to be impressed with the idea that danger lay mainly in the gelatin either produced or used in the course of the preparation of foods. The discussion may lead to further useful investigations but as the matter stands the laity, and even those partially initiated into the mysteries of bacterial action, will have to live in the hope that they may avoid danger, for apparently no easily applied method is known by which the presence of dangerous bacteria and ptomaines can be recognised, and it is obvious that every meat pie and joint of meat cannot be submitted to scientific investigation before it is eaten.

Midland Reafforestation.

Soma data suggestive of distinct advances in the near future were brought forward at the recent annual meeting of the Wolverhampton section of the Midland Reafforesting Association. Apparently, according to the report, no very large amount of planting has actually been done during the past year, 5½ acres of pit mound at Spring Vale and 3½ acres near the Bilston Fever Hospital representing the total of the planting, but the interest of landowners and others has been much stimulated. This is evidenced partly by inquiries and partly by the fact that villages on the outskirts of the district are taking the matter into their own hands and the people of Ocker Hill are planting trees in their own streets. These and other favourable signs indicate that probably in the near future opportunities for more extensive work will be placed in the hands of the Wolverhampton section of the above society.

March 31st.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Reformers.

THE annual meeting of the Manchester and Salford Sanitary Association was held on March 27th, under the presidency of the Lord Mayor. In moving the adoption of the report he spoke of the necessity of such an organisation to look after grown-up people, because it was they unfortunately who caused most of the trouble. He advocated better supervision of the milk-supply, for though no doubt as pure in Manchester as in any other city in the kingdom, "it did not follow that it could not be improved." They did not want to harass traders but to see that the supply should be "perfectly pure, or as pure as possible." The meeting was well attended, but it is not to the credit of Manchester that a society so useful, indeed so indispensable as a help to the official custodians of the sanitation of the city, should from the apathy and indifference of a large proportion of the well-to-do be crippled in many directions by want of funds. A widespread small subscription would in many ways be better than large sums from the few. An address was given by Mr. H. J. Tennant, M.P., on the "Children's Health Charter," and Mr. W. Thomson, F.R.S., gave a demonstration on the Air of Schools, &c. Mr. Tennant said that the medical inspection of school children should be only the first step towards a greater and wider scheme of school hygiene. The obvious corollary of it was medical treatment. It is, of course, much to be desired that when children require it they should be medically treated, but to some of us, who may be considered very backward, it seems not altogether wise to reduce parental responsibility to the vanishing point, and there may be a difficulty in doing all the parent should do and at the same time to guard against the loss to him of this sense of responsibility and of the family affection which would soon follow. Let help be given if need be, but so as to do as little injury as possible. Scoffers might say that surely if it is necessary for the community as a whole to assume the charge of the

Member of the Academy of Medicine and physician to the Asylum of Saint Anne, presented him with a medal in honour of his completion of 50 years' professional service. The President of the Council of Ministers and many professors of the Faculty of Medicine were present. Various speeches were made, amongst others one by M. Bajenoff in the name of sundry scientific societies of Moscow, and one by M. Lodame, speaking for Swiss experts in mental diseases. Dr. Magnan, who was much moved, warmly thanked those present in an eloquent speech. The medal, which is the work of M. Paul Richer, a Member of the Academy of Medicine and of the Academy of Fine Arts, bears on one side the bust of Dr. Magnan, while on the other he is shown surrounded by his patients and friends.

March 30th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Small-pox Scares.

SPORADIC cases of "vaiuolo nero," or black small-pox, occurring in Rome (but immediately isolated, with further spread of the disease circumscribed) have been magnified by report into something like an epidemic, much to the alarm of the public, resident or migratory. Hardly had this scare died down when another, this time affecting Naples, loomed large on the hygienic horizon, to disappear in turn under the searchlight of the public health officer. On March 24th the steamship *Montevideo*, of the "Compagnia Transatlantica" of Barcelona, hailing from Vera Cruz, dropped anchor in Neapolitan waters and immediately the rumour got abroad that ten cases of death from malignant small-pox had occurred among the passengers. The vessel was at once put in quarantine and a rigorous inquiry was instituted by the sanitary authority. Not one case of small-pox was verified but measles affecting 20 of the children on board was noted. The little patients were forthwith conveyed to the "*Ospedale Cotugno*" and the *Montevideo* was allowed to resume its voyage.

The "Bitter Cry" of the Cliniques.

Commenting on the recent State trial in Italy and the malversation to personal or political interests of funds reserved for schools and universities, THE LANCET drew attention to the deplorable condition of research and clinical work in Italy as "literally starved" in comparison with the same work in other nations. On March 26th His Excellency Signor Rava, Minister of Public Instruction, had a prolonged interview with a deputation of Piedmontese Members of Parliament on the "cliniche chirurgiche" in the University of Turin, all insufficient as those are for the requirements of the city and school. In the course of discussion His Excellency pointed out that Turin did not stand alone in asking from the Government increased support for its clinical accommodation and equipment—the Lombard school, represented by Pavia, being only another of the many seats of medical instruction clamouring loudly for similar aid. The Piedmontese deputies, however, had small difficulty in strengthening the claims of Turin to exceptional consideration and support, as the cost of land and of manual labour was much higher in the subalpine capital than in other Italian centres. His Excellency thereupon undertook to consult his colleague of the Treasury in the interests of Turin, with the result, it is hoped, of accelerating the measures required to put that great medical school on a level with its French, its Swiss, and its German sisters.

The Garibaldi Hospital.

True to his humanitarian ideal, the knight-errant of Italian freedom and unity left, among his death-bed dispositions, an injunction to found a hospital for the ailing or infirm poor among the islanders of the Straits of Bonifacio. His wishes have at length been complied with and the "Ospedaletto Giuseppe Garibaldi" on the Maddalena is now in effective working. With the exception of the "ambulatorio" (out-patient department) the hospital had recently been closed for reasons relating to the *personnel*. Donna Costanza Garibaldi (to whom the hospital owes so much) now writes to the *Tribuna* that the wards were reopened on March 25th (Feast of the Annunciation) under the supervision of a new directress who (*she says*) has been trained "nei primari ospedali Inglesi" (in the leading English hospitals).

Obstetric Aid to the Poor.

Thanks to the presence of a public-spirited physician in her communal council, Florence is now provided with organised aid to necessitous females "nei casi imprevisti e gravi del puerperio" (in unexpected and serious cases during and after parturition). Dr. Guido Banti, professor of pathological anatomy in the Istituto di Studi Superiori (the common councilman in question) was able to announce on March 27th that this service, instituted and organised by him, is quite gratuitous, one of the contributors to it being his colleague, Dr. Giuseppe Resinelli, professor of obstetrics and gynæcology, with the *personnel* attached to the "clinico d'ostetricia" in the same school. The movement is quite in keeping with Tuscan initiation in matters medical, of which (as I write) another instance reaches me from Rovezzano, where a series of popular lectures is to be addressed to mothers of families on the health conditions to be observed in their households. Dr. Lapo Falcioni of Florence will inaugurate the course on April 5th.

March 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Retirement of Professor Chrobak.

Professor Chrobak has resigned his position as professor of gynæcology and obstetrics, six years before reaching the legal limit, on account of his opinion that the work in the new clinic must be conducted by a younger man. He took leave of his former pupils and his fellow workers in the hall of the new clinic which will be available for the use of the public in a short time and a bust of him, beautifully executed by his daughter, was unveiled on this occasion in the hall as a good omen for the future of the new house. The assemblage included all his former assistants, most of whom are now professors and *privat-docenten*, representatives of the University and the medical staff of the army, his successor, and the staff of the medical faculty. Professor Chrobak thanked them for the many marks of kindness which they had shown to him and expressed confidence that the new clinics and the new hospital would once more as in former years attract the best men from all parts of Europe to work in Vienna. Continuing, he said that above all scientific work the physician and the surgeon must keep in mind that their first duty must be, "help, not harm"; and they must always do their best, whether in operation or in advice. Professor von Rosthorn, a former pupil of the retiring surgeon and now his successor, then described the remarkable individuality of Professor Chrobak who introduced the axiom that the function of medical or surgical intervention is only to help physiological processes. He said that in Professor Chrobak's operating theatre and lecture room the students would find displayed on the walls the admonition, "Primum non nocere." Professor Chrobak, who 19 years ago was with difficulty induced to accept the post of director of the clinic and clinical lecturer, soon made the clinic a notable place by the exactness of his diagnosis as well as by his surgical skill and the adoption of the newest methods of treatment. Dr. Peham, who is at present Professor Chrobak's first assistant, will act as temporary director of the clinic until Professor von Rosthorn takes over the new premises, which will not be before May or June.

A New Method of Approaching the Bulb of the Internal Jugular Vein.

Acting on a suggestion given by Professor Tandler, Dr. Bondy recently employed a new method of approaching the bulb of the internal jugular vein in a case of sinus thrombosis after acute mastoiditis, and the patient, who was a girl, was shown at a meeting of the Gesellschaft der Aerzte. She had been suffering from acute mastoiditis of two weeks' duration. As her temperature rose to 104·5°F. the mastoid process was opened and thrombosis of the sigmoid sinus was found. The thrombi were removed, but only the upper part of the sinus was afterwards freed for circulation. The lower portion of the thrombus could not be reached. As the temperature remained high and a rigor occurred it was resolved 24 hours after the first operation to open the bulb. The jugular vein had been ligatured the day before. The two incisions were united, thus exposing the sterno-mastoid muscle, which was retracted, and the spinal accessory nerve and the jugular vein were brought into view up to the jugular foramen. The facial nerve was also laid bare on the stylomastoid foramen, the apex of the mastoid process was removed, the biventer muscle was

Association as qualifying for graduation on the understanding, universal in the extramural school, that the lecturers should give the same system of instruction as was given by the professors in the University and should charge University fees. For years this arrangement has worked smoothly and, judged by the success of the women students at the degree examinations, admirably. The Scottish Association was, in fact, conducting a university college of medicine for women without any expense to the University and on the whole with remarkable efficiency and success. That all the classes and all the lecturers should be of equally high excellence could not be expected any more here than inside the University itself. The male student has, however, the privilege, which is no small one, to attend the class of an extramural lecturer when the professorial class does not attract him. This is a privilege which the women students are not granted, they must attend the lectures appointed by the Scottish Association. From time to time there is a recrudescence of agitation to have the women students admitted to the study of medicine on precisely the same conditions as men are admitted. The men students studying in Edinburgh for the University degree are, it is necessary to remember, allowed to take a considerable proportion of their classes outside the University—that is, to attend the class of an extramural lecturer on any particular subject, the extramural lecturers only acquiring this status on being recognised by the University Court as competent to lecture on their respective subjects. This is one form which the agitation takes and this is the form that appeals to the most forward agitators. They want the women to be allowed to attend the class of any professor or lecturer whom they may select and alongside the men. Another form which the movement takes is to get the University to take the medical education of women into its own hands and out of the hands of the Scottish Association. Those who favour this latter object dwell upon the disadvantages which the women labour under in the preliminary scientific subjects and in physiology from paucity of equipment as compared with the corresponding departments in the University, and they warmly urge the admission of women to any class where it is thought that the professor is friendly. The idea here is that admission to one class means getting the thin end of the wedge in and that it is only a question of persistent hammering to get it wholly in. Quite recently this agitation became acute, as Minto House was sold by its owner to a trading company and the Scottish Association found itself under notice to quit. This was at once seized upon as a heaven-sent opportunity for strong representations being made to the University Court to take the medical education of women into its own hands. The University Court, putting the idea of general mixed classes aside as not to be discussed, did not see its way to make any special provision for women students and therefore did not see any advantage in even discussing the position with representatives of the Scottish Association. Soon after this decision had been intimated the annual meeting of the Scottish Association was held. At this meeting a few of the lecturers were present, some lay members of the association, and the women students in full force. A motion was submitted by one of the leaders of the students expressing regret at the action of the University Court; an amendment was proposed by another student but the motion was carried by a large majority. This annual meeting elects the president, two vice-presidents, and three other members of the court of the association, the other four members being elected, two by the students and two by the board of studies—that is, the lecturers. The students are all members of the association and as there are over 100 students they only require to be organised to make the association represent their views. This year they were so organised and the annual meeting, after the chairman's statement was concluded, reminded one of a students' debating society. The speaking was good and warm in complexion. This is a fair representation of the position of those who are responsible for the present or recently acute phase of this agitation. The other side is as follows. The lecturers to the women in most instances lecture to men also but usually separately. In fact, the sanction of the University Court has to be obtained to have a class mixed and the sanction has to be obtained annually. The lecturers to the women are unanimously and strongly opposed to a general mixing of the sexes in the medical classes. This is also the view of the other extramural lecturers. It is understood that this view predominates amongst the medical professors. The men students are believed to be likewise opposed to such mixing. The active sympathisers, the majority of the women students and the women who write letters to the newspapers, see no reason why young men and young women should not sit side by side in the medical classes. The fact, however, remains that in the opinion of the great majority of lecturers, including probably professors, this is warmly opposed. This view is also, so far as is known, the only one held by the University Court. The students' view preponderates on the court of the association, as, of course, it is bound to do as soon as the students are organised on the lines indicated above. The position is a unique one and reminds one of Lord Dundreary's answer to his own conundrum: "Why does a dog wag its tail? Because if the dog didn't wag its tail the tail would wag the dog." Which is the dog and which is the tail may be left to the opinion of the two courts—the University Court and the court of the Scottish Association. Meanwhile it may safely be said that an agitation of this nature amongst students cannot but distract them from their studies and must foster a spirit of unrest and dissatisfaction which does anything but help either the teachers or the taught.

Church of Scotland Deaconess Hospital, Edinburgh.

The thirteenth annual meeting of the friends and supporters of this interesting charity has been held, with the Moderator of the General Assembly presiding over it. In the report submitted to the meeting it was shown that the number of patients who were treated in the hospital was 364, the average daily number being 24. The number of surgical operations performed was 268. The rate of mortality of patients under treatment was 4·3. The number of visits paid by the district nurses attached to the hospital was 4032. The number of surgical out-patients numbered 570. The total sum available for upkeep amounted to £1806, while the total expenditure was £1752. The chairman in his remarks indicated the hold which the hospital had taken on the members of their church and said that it was one of the best supported and the most popular of the church's agencies. The hospital authorities are to be congratulated on the economy with which the hospital is conducted as well as on the satisfactory state of their finances and the excellences of the work done by the members of the medical and the surgical staff.

Proposed Memorial of the late Professor Annandale.

A meeting has been called to consider what steps can be taken to establish a memorial of the late Professor Annandale.

Medical Relief of the Poor of Glasgow.

At a recent discussion under the auspices of the sanitary and social economic section of the Royal Philosophical Society of Glasgow interesting statistics were submitted regarding the medical relief of the poor in Glasgow. To give an idea of the number entitled to the services of the parish medical officers it may be stated that the number of persons on the roll for outdoor relief is 3581 and their dependents number 4544, making a total of 8125 possible patients. These figures, of course, refer entirely to the parish of Glasgow and to those who might be called the legal poor—i.e., those relieved under the Poor-law Acts. In addition, during last year 1477 medical relief orders were granted to persons not on the roll who, on account of their circumstances, were unable to provide medical attendance or medicines for themselves or for those dependent upon them. During last year the parish medical officers attended 10,576 patients either in their own homes or at the dispensaries. The total expenditure incurred during the year in outdoor relief was £3001, of which £1101 were expended on medicines and the remaining £1900 represented the combined salaries of the 19 medical officers. On the year's working the average cost per patient was 5*s.* 8*d.*, of which 2*s.* 1*d.* represented the cost of medicines, &c., and the balance, 3*s.* 7*d.*, represented the cost of medical attendance. It is to be noted that the cost of medical attendance would be less if the medical officers' duties were confined to dealing with cases of sickness only. Under the present system, however, every applicant for parish relief must be examined by a medical officer and a certificate given as to the state of his health on every application, no matter how short an interval elapses between each. As regards indoor medical relief, the parish council of Glasgow provides for the care of the sick and indoor poor as follows: Stobhill Hospital, with accommodation for 1922 patients; Eastern Hospital, 380 patients; Western Hospital, 260 patients;

was taken from the polluted water of rivers and was the undoubted source of the fever. The total number of cases originating on this vessel is estimated to be 200, but the number which resulted from those landed at different places, and from passengers who were sick of the fever after leaving the vessel, cannot be estimated. It now appears that the source of much, if not all, of the enteric fever occurring on the passenger vessels on the lakes is due to the custom of these vessels of obtaining their supply of drinking water from the polluted rivers at the mouths of which the chief cities are located. It is also believed that the practice of landing passengers sick from enteric fever at the various cities on the route has made these vessels carriers of the pestilence. The Surgeon-General has taken prompt action and has appointed a competent commission to investigate the question of the responsibility of these passenger vessels for the dissemination of enteric fever.

The Unnecessary Noise Law.

The New York Society for the Suppression of Unnecessary Noises had been successful in securing the passage of an ordinance to prevent noise in the vicinity of hospitals and places where the sick and aged are cared for and the result is very favourable. Sign-boards are posted on the corners of the streets near by announcing a "hospital district." So successful has this effort been that the society has introduced a Bill into Congress intended to suppress unnecessary whistling of steam vessels plying in harbours about large cities. The particular harbours referred to are Boston, New York, and Philadelphia, but the Bill is general in its provisions. It has already passed the Upper House and will in due time become law.

The Finger-Licking Habit.

The medical society of the city hospital alumni of St. Louis, Missouri, has sent to the Postmaster-General, the city postmaster, and the Health Department, a communication requesting that effective measures should be taken to protect the public against danger from the practice of habitual insalivation of the fingers by those who handle mail matter. The society desires that employees addicted to this habit who, in the performance of their duties as stamp sellers, postmen, clerks, cashiers, salespeople, waiters, conductors, and so on, are necessarily in contact with the public, and who persist in so doing after notice and warning, should be deprived of their positions as thereby constituting a menace to the general health. Sanitary and medical condemnation of the practice of finger-licking rests on the proved fact that the bacteria of many of the most virulent diseases are often abundantly present in the secretions of the human throat and mouth. The paper closes with a resolution that the St. Louis Health Department should be requested to investigate and publicly to report on the prevalence of the habit of finger-licking among the employees of the departments, corporations, and concerns serving, or catering for, the people of St. Louis in order that warning may be given of the risks to health incurred by patronising places, public utilities, and establishments where such an unclean and dangerous practice is permitted.

The Plague in San Francisco.

There has been a renewed outbreak of the plague in San Francisco, proving that the infection still has a foothold in some locality. The number of cases is very small but sufficient to arouse the health authorities and the citizens to renewed efforts to clear the city of every possible source of infection. A large fund is being raised to supply an increased corps of inspectors and to meet any extraordinary expenses. The bounty on rats has been increased to 25 cents for males and 50 cents for females. A citizens' health committee has been formed to coöperate with the health department.

March 21st.

GLOUCESTER INFIRMARY.—The annual meeting of the subscribers to the Gloucester Infirmary and Gloucestershire Eye Institution was held on March 26th. The medical report stated that 1390 in-patients were admitted during 1907, an increase of 91 as compared with 1906. The out-patients numbered 8412, being 500 less than in the previous year. The average cost per bed was £84. The financial statement showed that the deficit of £956 remaining at the close of the year 1906 was now reduced to £186.

Medical News.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in March the following candidates passed in the subjects indicated :—

DEGREES OF M.B. AND CH.B.

Final Examination.—John Allen, C. G. Howlett, J. L. Moir, J. V. Steward, B. V. Ward, and Edgar Wharton.

Obstetrics.—F. D. Walker.

Forensic Medicine and Toxicology.—J. A. Bateman, R. J. Batty, T. B Bolton, Elsie Brown, W. C. Denniston, Frances M. Huxley, M. C. S. Lawrance, E. K. Lomas, W. P. Marshall, W. W. Martin, John Morley, John Thompson, R. B. Thompson, B. W. B. Trevor-Roper, W. W. Uttley, T. G. Williams, and A. E. Woodall.

Second Examination.—A. R. Ainscow, Rupert Briercliffe, John Cowan, Caleb Davies, E. R. Eatock, Edgar Grey, Harold Heathcote, R. C. Hutchinson, R. B. Jackson, Geoffrey Lapage, Mabel E. May, W. J. A. Quine, J. R. Rigg, J. B. Scott, W. A. Sneath (awarded distinction in anatomy and the University prize in medicine), J. P. Stallard, Charlotte E. Warner, and Gordon Whitehead.

Third Examination (New Regulations).—Pharmacology and Therapeutics.—H. E. Allanson, C. G. Brentnall, W. A. Bullough, D. I. Connolly, F. H. Diggle, H. A. Dunkerley, Gertrude H. Geller, John Gow, T. T. Higgins, N. T. K. Jordan, Niel McDonald, C. B. Marshall, Cedric Pimblett, *Harry Platt, T. M. Popple, James Ramsbottom, A. A. Smalley, Norman Tattersall, R. H. Titcombe, and J. F. Ward.

General Pathology and Morbid Anatomy.—H. E. Allanson, C. G. Brentnall, W. A. Bullough, *D. I. Connolly, F. H. Diggle, Gertrude H. Geller, *John Gow, T. T. Higgins, N. T. K. Jordon, Niel McDonald, Edith M. Marsden, C. B. Marshall, Cedric Pimblett, Harry Platt, James Ramsbotrom, A. A. Smalley, Norman Tattersall, R. H. Titcombe, W. B. Wamsley, and J. F. Ward.

Public Health.—Elsie Brown, H. A. Dunkerley, W. W. Martin, Cedric Pimblett, T. M. Popple, and James Ramsbottom.

* Passed with distinction.

DIPLOMA IN DENTISTRY.

Third Examination.—Joseph Morrey.

Dental Anatomy and Histology.—T. B. Smith.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—In examinations held in March for the Degree of Bachelor in Medicine the following candidates were successful in the subjects indicated :—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry and Physics.—Harold Fairclough (second-class honours), Eric Lawrence Hancock, and James Kenworthy Johnston Haworth, College of Medicine, Newcastle-upon-Tyne ; John Robert Dunn Holtby, Queen's College, Belfast ; and Edwin Kidd, Colin Mearns, Fred Phillips, and Alexander Gordon Taylor, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—Fife Appleton, Ronald Greig Badenoch, William Leitrim Clements, Arthur Tannahill Crilley, Norman Hodgson, James Kerr, Francis James Lidderdale, Sydney Ellington Murray, Andrew Govan McFarlane, John George Ogle, Charles Henry Robson, Sidney Scott, William Arthur Slater, Thomas Copeland Storey, and Samuel Knibb Young, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—Robert Ernest Bell and Arthur Sydney Hopgood, College of Medicine, Newcastle-upon-Tyne; and Russell Vyvyan Steele, University College, London.

Elementary Anatomy.—Sam Phillips Bedson and Theonie Bence Burrell, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy, Chemistry, and Physics.—William Guy Lidderdale, College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—William George Bendle, Eliot Watson Blake, and Francis Percy Evers, College of Medicine, Newcastle-upon-Tyne ; Ivor Stanley Gabe, College of Medicine, Newcastle-upon-Tyne, and London Hospital ; Cyril Gray, Howard Tomlin Hunter, George Eric Warner Lacey, and Thomas Alfred Peel, College of Medicine, Newcastle-upon-Tyne ; Elliot Jessie Ramsbotham, London School of Medicine for Women ; Harold Frieze Stephens, Madras Medical College and Guy's Hospital ; and Alfred Tulloch Thompson and Charles Sim Thompson, College of Medicine, Newcastle-upon-Tyne.

TRINITY COLLEGE, DUBLIN.—At Examinations in medicine in Hilary term the following candidates were successful :—

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Herbert de L. Crawford, Douglas M. Moffat, Hugh E. M. Ferguson, Arnold K. Henry, George F. C. Healy, Thomas A. Watson, John B. Burgess, Ernest W. G. Young, Thomas M. Crawford, Richard P. Pollard, Charles H. Denham, James Beckett, and Cecil Grene.

Part II.—Adrian Stokes, Charles M. Finny, David L. M'Cullough, Marius A. Diemont, Beatrice Hamilton, John H. Woodroffe, Peter H. Lemass, Herbert de L. Crawford, Robert Dixon, Douglas M. Moffatt, Roelof A. Albertyn, Euphon M. Maxwell, Edmond F. Lawson, Perceval G. Leeman, Thomas M. Crawford, Hilgard Müller, William P. H. Smiley, Vicars M. Fisher, John G. Ronaldson, Arnold K. Henry, John B. Burgess, George F. C. Healy, John G. Dods, Samuel V. Richardson, Arthur C. Hallowes, Victor B. Best, Richard H. Mathews, Charles H. Denham, and Brindley H. Moore.

1907. Of these, 1305 were medical and 1775 were surgical. There were 1360 surgical operations. The average mortality was 4·09 per cent. In the extern department 29,433 were treated. The total number of cases (dental included) treated in the hospital, intern and extern, amounted to 32,513, while at the Martins Children's Hospital, at the Throne Convalescent Home, and in the consumptive department 334 convalescents were received and 116 children were treated, as well as 47 consumptive patients. The following figures give some idea of the work of the hospital. During the year 1583 ambulance cases were received, 1360 operations were performed, and there was an average of 465 patients treated every day in the year, of whom 223 occupied beds in the hospital. Financially for the first time in the history of the new hospital there was an excess of expenditure over receipts of £548. The Right Rev. Dr. Crozier, Bishop of Down, who presided, in moving the adoption of the report, spoke very warmly of the value of the institution in training the rising generation of medical men. Among the members of the medical profession who spoke at the meeting—which was very largely attended—were Dr. H. L. McKisack (secretary of the medical and surgical staff), Sir John Byers, and Dr. W. Calwell.

The Belfast Samaritan Hospital.

At the annual meeting of the supporters of this charity (the Lord Mayor presiding) on March 23rd it was reported by Dr. G. A. Hicks that during the past year 683 patients had been treated in the extern and 200 in the intern department of the hospital. Financially the debt at the end of the year was reduced to £89 and a sum of over £3000 is invested. In their report the medical staff suggested that as the wives of men of the labouring class as distinguished from the artisan class have from time to time to be refused admission owing to their not being able to pay the minimum fee of 10*s.* per week, such cases after admission should have a rate fixed by the ladies committee on inquiry into their circumstances. This procedure when used in other hospitals works satisfactorily.

The "Abbey" Sanatorium for Pulmonary Tuberculosis.

Mr. Robert Hall, physician to the Belfast union infirmary and to "The Abbey" sanatorium for pulmonary tuberculosis, has just presented to the sanatorium committee of the Belfast board of guardians a most interesting annual report as to the condition of patients who were treated for consumption in that excellent institution during 1907. During this period 311 patients were treated, of whom 163 (40 married, 14 widowed, and 109 single) were women and 148 (48 married, 13 widowed, and 87 single) men. Of these 115 are still under treatment. Of these 311 patients the following was the age incidence :—

From 5 to 10 years of age	6
" 10 " 20 "	59
" 20 " 30 "	100
" 30 " 40 "	82
" 40 " 50 "	45
" 50 " 60 "	14
" 60 " 70 "	5
Total	311

These are statistics which prove that advancing age does not give immunity from pulmonary tuberculosis. Of the 196 patients who left the sanatorium during the year 30 per cent. were so much improved that they returned to their ordinary avocations; 33 per cent. were considerably improved but were not able to do full work; and the remaining 37 per cent. remained in a stationary condition or the disease being in a too advanced stage on admission did not respond to treatment. 10 per cent. of the total number (311) treated died. Mr. Hall expresses the regret that so many persons when they are attacked by pulmonary tuberculosis either do not appear to realise the absolute necessity for early treatment or the gravity of their condition till they are completely broken down in health and frequently in a stage of disease when there is little or no hope of cure; if they did he thinks that there would not be so many hopeless cases admitted to the wards of the institution or so many homes poisoned by the germs emanating from the advanced cases. Mr. Hall says in admitting patients preference when possible was given to the "bread earners," and he points out the great benefit and possibility of an open-air life, for at least 25 per cent. of the patients slept on the verandahs during the winter. He advocates compulsory notification of pulmonary tuberculosis and he points out that patients transferred from the union infirmary to the sanatorium showed a distinct advance in their progress. Quite recently (since this report was written) the hospital block has been opened for the reception of patients and has been almost filled by the transference of patients from the union infirmary—the number at present under treatment being 256. It is interesting to note that since Mr. Hall took the great forward step—nine and a half years ago—of separating the consumptives from the other patients in the Belfast union infirmary (the first union infirmary in Ireland where this segregation of consumptive patients was done) over 6000 such cases have been treated in the infirmary and sanatorium. The Belfast board of guardians and its excellent medical officer, Mr. Hall, have in their treatment of consumptive patients given an object-lesson to the rest of Ireland.

March 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Action of Radium on the Blood.

AT a meeting of the Biological Society held on March 14th M. Aubertin and M. Delamarre communicated the result of some researches which they had made as regards the action of radium upon the viscera and especially upon the blood-forming organs. White mice were submitted to radium emanations, the effects brought about being very similar to those produced by the x rays. After exposure to the emanations for one hour marked leucocytosis occurred. Sometimes, however, during the second hour a marked diminution in the number of leucocytes occurred, which persisted more or less after the radium had been withdrawn. During this period the blood counts showed an excess of polynuclear cells, and leucocytes in course of histolysis were found in the blood. Daily exposure to the emanations brought about marked leucopenia and a diminution in the number of red cells. Prolonged exposure to the rays gave rise to necrosis of the follicles of the spleen and a fragmentary condition of the Malpighian bodies (*noyaux*). An irradiation of less duration did not give rise to any splenic lesion but leucopenia was very marked.

An Ambulance drawn by a Dog.

Lieutenant Paisais, of the camp at Ruchard, proposes the employment for ambulance work of a wheeled stretcher drawn by a dog. The ambulance is mounted on a spring four-wheeled carriage The front wheels are 49 centimetres in diameter and the hind wheels 60; the axles are removeable at pleasure. A trial of this method of transport was made at Poitiers with a policeman acting as the wounded man and the dog mounted without difficulty a gradient of very considerable pitch; on the return journey, instead of the policeman, the stretcher was loaded with 90 kilogrammes of sand (about 14 stones). The weight of the stretcher and the carriage is 30 kilogrammes and in the absence of the dog can easily be drawn by a man or even by a child.

Quinine in Algeria.

The Syndicate of Pharmacists of the department of Algiers has approved in principle of the sale of quinine at a price and in a form laid down by the Government. The syndicate hopes, by giving its approbation to these regulations, that the risk of the sale of quinine falling into the hands of foreigners will be avoided.

The Treatment of Hæmarthrosis.

At a meeting of the Surgical Society held on March 11th M. Lucas-Championnière recommended light massage applied directly to the muscles in the treatment of hæmarthrosis, and, contrary to the experience of some other observers, he considered that massage alone was sufficient to obtain muscular regeneration. Gentle massage of the joint should also be practised with passive movement, but care should be taken that no pain is produced. Any active movement should be made with great caution and should only last for a very short time. As to the regeneration of the muscular tissue M. Lucas-Championnière thought that no good result could be obtained by demanding a maximum of effort from the muscle at the outset, for this demand, he said, would be very likely to bring about muscular atrophy.

Jubilee of Dr. Magnan.

Quite recently the pupils and friends of Dr. Magnan, operative surgery, practical chemistry, public health and forensic medicine, materia medica, histology, biology, and dissections.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Mr. Winfrey's Pharmacy Bill.

THIS Bill has been printed. In a memorandum explaining its objects it is stated that it differs from the measure introduced last session by Mr. WINFREY in that the cumbersome expedient of the registration of shops has been superseded. The clause requiring a company to have a qualified chemist as one of the directors has also been omitted. The objects of this Bill are to check (*a*) the evils arising from unqualified management of shops in which medicines are dispensed and poisons are retailed; and (*b*) the assumption of the statutory title of "chemist" by unregistered persons. The Bill would insure that in every place where poisons are retailed there shall be a qualified person in *bonâ-fide* control, and his name shall be exhibited to the public whether the owner of the business happens to be a natural person or a corporate body. The measure further seeks to enforce the intention of the Pharmacy Acts of 1852 and 1868 by prohibiting the use of the title of qualification by any person or combination of persons other than the actual living holders of the diploma of qualification. The Bill substitutes for the existing list of poisons another schedule of substances of a dangerous nature in the sale of which the public requires to be protected. A clause is also added permitting the establishment of reciprocal relations with the colonies in the acceptance of certificates of pharmaceutical qualification.

Housing and Town Planning Legislation.

Mr. BURNS, the President of the Local Government Board, has introduced into the House of Commons a Bill "to amend the law relating to the housing of the working classes, to provide for the making of town planning schemes, and to make further provision with respect to the appointment and duties of county medical officers of health." It has been read a first time. The Bill proposes great facilities for acquiring lands on the part of local authorities and for taking advantage of the Housing Acts. The procedure for making closing and demolition orders is amended. A town-planning scheme may be made with the authorisation of the Local Government Board by a local authority "as respects any land which appears likely to be used for building purposes with the general object of securing proper sanitary conditions, amenity, and convenience in connexion with the laying out and use of the land." Elaborate conditions with regard to this provision are embodied in the Bill. A clause in the Bill relates to county medical officers. It runs thus: "(1) Every county council shall appoint a medical officer of health under Section 17 of the Local Government Act, 1888; (2) the Local Government Board may by order prescribe the duties of medical officers of health appointed by a county council under Section 17 of the Local Government Act, 1888, whether before or after the passing of this Act; (3) the power of county councils and district councils under the said section to make arrangements with respect to medical officers of health shall cease without prejudice to any arrangement made previously to the date of the passing of this Act." Another clause makes it the duty of the clerk and the medical officers of health of a district council to furnish information to the medical officer of health of the county council. The question of the tenure of medical officers of health of their appointments will lead to debate.

Infant Life Protection.

The Select Committee of the House of Commons presided over by Mr. JOHN ELLIS has recommended in its report that the inspection provided under the Infant Life Protection Act of 1897 should be extended to homes in which not more than one infant is kept in consideration of periodical payment, and also that the age of inspected children should be raised to seven years. The illustrative cases which were given of carelessness, neglect, bad treatment, and cruelty in "one-child homes" have induced the committee to make these recommendations. However, the members of the committee have, to some extent at least, recognised some of the objections urged against the extension of the Act as deserving of serious consideration. It was stated by one category of witnesses that the inspection of "one-child homes" would arouse great repugnance on the part of those who provide the best kind of homes to continue to take in children and that the difficulty of finding such homes would therefore become very great. The members of the committee place on record their belief that there are a large number of these one-child cases where the infant is received from motives of a real affection for children in general or for some child, or parent, in particular. Where this element of a home atmosphere exists it is of vital importance that nothing should be done by Act of Parliament, or what would flow therefrom, to chill or to impair it. On a careful review of this aspect of the case, they come to the conclusion that some power should be given to the local authority to exempt, on such terms and conditions as it may think fit, any particular home in its district from inspection, or to make arrangements for any such inspection to be made by a properly constituted benevolent society if the local authority is satisfied that the interest of the child will be safeguarded. Another recommendation of the committee is to the effect that the inspection under the Infant Life Protection Act, especially if extended in the manner which the report suggests, should as far as possible be deprived of any rigid or formal official character, and should certainly be carried out by women possessing special qualifications for the work. When the committee was appointed it was intended that its recommendations should guide Parliament in shaping the clauses of the Children's Bill relating to infant life protection.

Public Health Bill.

Mr. COOPER's Bill to amend the Public Health Act, 1875, and the Local Government Act, 1888, has been published. A memorandum is attached to it to explain its provisions. It states that "the object of the Bill is to make the council of an administrative county as defined by the Local Government Act, 1888, the predominant sanitary authority of such county and to give it power to supersede any local authority in the county which may neglect or refuse to carry out any of its statutory duties. It is proposed to require every county council to appoint at least one whole-time medical officer of health holding a diploma of public health. Every medical officer of health of a local authority appointed after the Bill comes into operation must hold a diploma of public health. Every local authority will be empowered to appoint as many sanitary inspectors as may be necessary to efficiently inspect its area, and such authorities will be empowered to appoint health visitors. The appointment by a local authority of a medical officer of health or sanitary inspector or health visitor will be subject to the approval of the county council, and every such officer on dismissal may appeal to the county council who may reinstate such officer if they think fit."

University Bill for Ireland.

Mr. BIRRELL's University Bill for Ireland, which was introduced on Tuesday, March 31st, has been received very favourably.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 25TH.

The Medical Officer for the Witwatersrand Mines.

Mr. STAVELEY-HILL asked the Under Secretary of State for the Colonies whether the post of district medical officer for the Witwatersrand mines had yet been filled; and, if not, whether he would suggest to the Transvaal Government the urgent importance of filling the vacancy with a highly qualified man in view of the heavy mortality among the natives working in the mines.—Mr. CHURCHILL replied: I regret that I cannot add anything to my previous replies to questions on this subject.

THURSDAY, MARCH 26TH.

Tuberculosis in the Army.

Colonel LOCKWOOD asked the Secretary of State for War what steps (if any) were, or would be, taken to carry out the recommendations of the special War Office committee with regard to soldiers suffering from tuberculosis and making provision for their reception into suitable sanatoriums and thus preventing the spread amongst the civilian population in their own homes of a disease which was killing off some 40,000 of our population annually.—Mr. HALDANE replied: Will the honourable and gallant Member kindly refer to my replies to previous questions put to me on this subject by the honourable Member for Sunderland on Feb. 18th and the honourable Member for the Abercromby Division of Liverpool on March 2nd, to which I have nothing to add?

The Importation of Foreign Meat.

Answering Mr. BOLAND,

Dr. MACNAMARA (Parliamentary Secretary to the Local Government Board) said: I do not think that any special action is necessary at the present time as regards the importation of bacon and meat from Denmark, but I have in preparation regulations dealing generally with the measures to be taken for the prevention of danger to health from the importation of foreign meat.

The Prevalence of Scarlet Fever.

Mr. REMNANT asked the President of the Local Government Board what action he proposed to take relative to the resolution unanimously passed by the managers of the Metropolitan Asylum District on Dec. 7th, 1907, and supported by the corporation of the City of London and generally by the borough councils and boards of guardians of the metropolis, asking the Local Government Board, in view of the continued prevalence of scarlet fever, notwithstanding the extensive isolation accommodation which had been provided, to cause an inquiry to be instituted into the cause of the disease; and whether any, and, if so, what, further means could be adopted for its prevention.—Dr. MACNAMARA (on behalf of Mr. BURNS) answered: I have received the resolution referred to which has been supported by various borough councils and boards of guardians. I am giving consideration to the subject but have not yet arrived at a decision with regard to it.

The Medical Needs of St. Helena.

Major ANSTRUTHER-GRAY asked the Under Secretary of State for the Colonies whether, in view of the fact that the inhabitants of St Helena, numbering about 5000, had only one medical man to attend to their needs, he would consider the advisability of appointing an assistant colonial surgeon.—Mr. CHURCHILL answered: The number of inhabitants of St. Helena at the last census in May, 1901, was 3342, not 5000, and there is reason to believe that the number has been reduced since that date. The question of appointing an assistant colonial surgeon has been considered on several occasions but it has not been found advisable to do so. There is an efficient hospital with a staff of trained nurses to supplement the services of the colonial surgeon.

Disease in the Transvaal Mines.

Mr. MACKARNESS asked the Under Secretary of State for the Colonies whether he could say how many Chinese labourers had been deported loosened, and after ligature of the occipital artery the bone covering the sinus and bulb was removed with the chisel, the anterior margin of the field of operation being marked by the facial nerve. In this way the whole vessel, consisting of the sinus, the bulb, and the internal jugular vein, was exposed and opened, whereupon the remainder of the thrombus was removed. It consisted of a yellow thick mass full of streptococci. The patient made an uneventful recovery except for a slight paresis of the facial nerve, probably caused by dragging on the nerve during the operation. The main advantage of this method as compared with the older operation of Grunert was the fact that the accessory nerve was not injured.

Ultra-Violet Rays in the Treatment of Syphilis.

In a series of experiments, the results of which have been communicated to the Gesellschaft der Aerzte, Professor Ehrmann has studied the effects of ultra-violet light (uviol light) on the pigment anomalies of the skin, and in the course of the investigations he noticed that syphilides of the skin, especially on the parts generally covered by the clothing, responded very quickly to the rays. The exposure lasted only for a short time so that there was merely a slight reaction unattended with erythema. The effect was decrease of the swelling and pigmentation on the second day, while the efflorescences dried up on the next day and eventually disappeared. A gumma of the skin was exposed to the rays three times; four days later it was covered by healthy epidermis and became almost entirely absorbed. The method would therefore, he considered, be valuable for the local treatment of refractory syphilitic lesions of the integument. Control experiments showed that the action of the rays was confined to the exposed space. For instance, the left arm could be made to appear healthy whilst the right arm which was treated by means of mercury without exposure to the rays still showed the exanthem.

Problems of Growing and Living.

By invitation of the Vienna Society for Internal Medicine and Pædiatrics Professor Rubner of Berlin, who has made a special study of questions relating to development and growth, delivered a lecture on this important subject at a recent meeting of the society. He said that the main factor influencing the growth of the child was the inherited rate of cell proliferation and cell division, and that it was not entirely dependent on the quantity of calories contained in the food ingested. The weight of the newly born creature was doubled by growth in very different intervals in different animals. For instance, to double its weight the newly born progeny of the cat required nine days, that of the rabbit six days, that of the dog nine days, that of the pig 14 days, that of the sheep 15 days, that of the cow 47 days, and that of the mare 60 days, while the human infant required 180 days. Intensity of growth was therefore very variable, but the quantity of energy required to bring about this doubling was remarkably equal in all these animals, being about 4000 calories per kilogramme of the body-weight, whilst in man it was 29,000 calories. Of the entire quantity of energy represented by the food ingested, the lower animals required about 34 per cent. for growing, whereas man required only 5 per cent. The milk of the different species therefore showed in its percentage composition the same variety in regard to quantity as was shown by the energy required for the process of growth. The only function of the sugar and fat in milk was to reduce as much as possible the metabolism of albumin in the body, so that the largest possible quantity of albumin might be free to serve the purpose of growth. The slow growth of the human body was perhaps compensated by the greater development of the brain. Man had, moreover, an exceptional position in regard to the duration of life and its relation to the duration of the period of growth. Whilst the horse lived 35 years, the cow 30 years, and the dog 11 years, the period of growth of these animals was respectively five, four, and two years —i.e., from one-sixth to one-seventh of the total duration of life. In man, on the other hand, a total duration of life varying from 70 to 80 years was associated with a period of growth from 20 to 24 years—i.e., from one-third to one-fourth of the whole duration of life was spent in the development of the body. After the completion of growth the above-mentioned animals required in their food approximately 190,000 calories per kilogramme of body-weight on an average, whilst man required 725,000 calories per kilogramme of body-weight. The living substance of man was therefore far more active in metabolism than the living substance of other warm-blooded animals; the older opinion that the contrary was the case was erroneous. The termination of life was perhaps best explained by the hypothesis that the dissociative quality of the protoplasm was exhausted when it had accomplished a certain amount of work which was equal in every species.

March 30th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Physicians as Witnesses.

THE medical profession has become sensitive as to the reputation which medical expert witnesses have acquired in the courts and various efforts are being made in different States to improve the situation. The public have come to believe that the medical expert occupies the same relation to the parties in whose behalf he testifies as does the legal counsellor—viz., a paid and therefore a partisan witness. The remedy most popular with the profession is such legislation as will authorise the courts to appoint official experts who shall be delivered from temptation by having their compensation fixed by the courts and paid by the county. This plan is opposed by the legal fraternity on the ground that it does not take into consideration the rights of the individual whose life, liberty, and property may depend upon some fact which can be ascertained only by the aid of the testimony of medical experts. A leading authority holds that the proposed legislation would infringe one of the most important of the rights of persons accused of crime—viz., the right of impartial trial and of having compulsory process for the attendance of witnesses. If opinion evidence is to be received at all it would be manifestly unjust for the law to say that the court should receive the opinion of particular individuals only, and that all others should be excluded, however eminent they might be in their special department of science.

First Naval Hospital Ship.

The United States naval hospital ship *Relief* at Mars Island, San Francisco, under the command of a surgeon, has been commissioned in accordance with the recent order of the Secretary of the Navy. This order has created much criticism and led to the resignation of the head of the Bureau of Navigation. It grew out of a decision of the Surgeon-General of the Navy that hospital ships should be under the sole control of the surgeon. This innovation was resented and violently opposed by officers of the line as destructive of discipline and efficiency but the Surgeon-General was sustained by the President and the outcome of the controversy is the fully equipped hospital ship *Relief*, with Surgeon C. F. Stokes, U.S.N., in command and Captain Le Cain of the auxiliary service as navigator. The *Relief* has accommodation for 200 patients and is as well arranged for hospital service as the best hospital on land. There are two general wards and a ward for commissioned officers. The operating room is as perfect in all its details as art and science can make it. Adjoining it is an x ray outfit, with photographic plant and dark room. There are laboratories for bacteriological and pathological research, with culture media of the most approved kind. There is a powerful refrigerating plant with facilities for cold-storing a large supply of fresh provisions and a disinfecting apparatus and an embalming department are provided. A dental office in charge of a graduate dentist is an important part of the outfit. The success of the hospital ship under the control of a surgeon will be awaited with great interest by the parties to the controversy.

The Sanitary Responsibility of Public Carriers.

The Buffalo Academy of Medicine has petitioned the Surgeon-General of the United States Public Health Service to investigate the source of enteric fever occurring among the passengers on the steamers on the Upper Lakes. This action grew out of an outbreak which occurred on a steamer plying on the lakes and which continued for three weeks, during which the sick in different stages of the fever were landed at several cities *en route*. Many passengers were taken sick after leaving the ship and on arriving at their homes. On investigation it was found that the milk was foul, the drinking water contained the colon bacillus, and the vessel was in an unsanitary condition. The water-supply

MACMILLAN COMPANY, THE, New York. (MACMILLAN AND CO., LIMITED, London.)

Biological Studies and Addresses. Vol. I., Evolution of Mammalian Molar Teeth to and from the Triangular Type, including Collected and Revised Researches on Trituberculy and New Sections on the Forms and Homologies of the Molar Teeth in the Different Orders of Mammals. By Henry Fairfield Osborn, Sc.D., LL.D., D.Sc., Dacosta Professor of Zoology in Columbia University; Curator of Vertebrate Palæontology in the American Museum of Natural History. Edited by W. K. Gregory, M.A., Lecturer in Zoology in Columbia University. Price 8*s.* 6*d.* net.

The Animal Behaviour Series. Volume II., The Animal Mind. A Text-book of Comparative Psychology. By Margaret Floy Washburn, Ph.D., Associate Professor of Philosophy in Vassar College. Price 7*s.* net.

RENSHAW, HENRY, 356, Strand, London.

A Manual of the Practice and Theory of Medicine. By Sir William Whitla, M.A., M.D., LL.D., Senior Physician to and Lecturer on Clinical Medicine, Royal Victoria Hospital; Professor of Materia Medica and Therapeutics in Queen's College, Belfast. In two Volumes. Price not stated.

RICHARDS, GRANT, 7, Carlton-street, London.

The Birds of the British Islands. By Charles Stonham, C.M.G., F.R.C.S., F.Z.S. With Illustrations by Lilian M. Medland. In Twenty Parts. Part IX. Price 7*s.* 6*d.* net.

SANDS AND CO., London and Edinburgh. (HERDER, B., 17, South Broadway, St. Louis, Missouri, U.S.A.)

The Medical Annual: A Year-book of Treatment and Practitioner's Index. 1908. Twenty-sixth year. Price 8*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERTON, E. W., M.B., B.S. Vict., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Hawes District of the county of York.

BARRIS, J. D., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the City of London Lying-in Hospital.

COOPER, H. G., M.B., B.C. Cantab., has been appointed Public Vaccinator for the Altrincham District of Cheshire.

ELDER, ELIZABETH F., M.B., Ch.B. St. And., has been appointed Assistant Medical Inspector of School Children by the Cardiff Education Committee.

FEDDEN, W. FEDDE, M.S., M.B. Lond., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at the Kentish Town Department of the Hampstead General and North-West London Hospitals.

HAWTHORNE, C. O., M.D. Glasg., M.R.C.P. Lond., has been appointed Physician to Out-patients at the Kentish Town Department of the Hampstead General and North-West London Hospitals.

HERAPATH, CHARLES EDWARD KYNASTON, L.R.C.P. Lond., M.R.C.S., has been appointed Junior House Surgeon at the Bristol Royal Infirmary.

KEMP, CHARLES GORDON, M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Casualty Officer at the Bristol Royal Infirmary.

O'KEEFFE, MARTIN, L.R.C.P. Irel., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ovoca District of the county of Wicklow.

PARKER, WILLIAM GIBSON, M.B. Lond., D.P.H. Cantab., has been appointed Assistant Medical Inspector of Schools by the Somerset Education Committee.

PIRIE, W. RATTRAY, M.B., C.M. Aberd., has been appointed Assistant Physician at the Aberdeen Royal Infirmary.

PRICE, F. W., M.B., C.M. Edin., M.R.C.P. Lond., has been appointed Physician to Out-patients at the Kentish Town Department of the Hampstead General and North-West London Hospitals.

RIDOUT, C. A. SCOTT, M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Portsmouth Hospital.

RUNDLE, HENRY, F.R.C.S. Eng., has been appointed Consulting Surgeon to the Royal Portsmouth Hospital.

SAVEGE, JAMES, C.M., M.D. Aberd., has been appointed a District Medical Officer and Public Vaccinator to the Sculcoates (Hull) Board of Guardians.

SMITH, G. F. DARWALL, M.B., B.Ch. Oxon., F.R.C.S. Eng., has been appointed Physician to Out-patients at the British Lying-in Hospital, Endell-street, London.

THOMAS, EDMUND FAIRFIELD, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Assistant Medical Inspector of School Children by the Cardiff Education Committee.

TROUP, ARTHUR G., M.B., Ch.B., D.P.H. Aberd., has been appointed Assistant Pathologist at the Sussex County Hospital, Brighton.

WALKER, J. W. THOMSON, M.B., C.M. Edin., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon to Out-patients at the Kentish Town Department of the Hampstead General and North-West London Hospitals.

WHITEHEAD, A. E., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bridlington District of the county of York.

WRIGHT, ANDREW J. M., M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Obstetric Officer at the Bristol Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYR DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

BIRMINGHAM INFIRMARY.—Assistant Resident Medical Officer. Salary £104 per annum, with apartments, rations, &c.

BRISTOL ROYAL INFIRMARY.—House Physician. Salary £100 per annum, with apartments, board, and laundry.

CAMBRIDGE, BOROUGH OF.—Medical Officer of Health. Salary £500 per annum.

CAMBRIDGESHIRE, &C., ASYLUM, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.

CANCER HOSPITAL (FREE), Fulham-road, London, S.W.—Honorary Physician. Also Dental Surgeon.

CARMARTHEN, JOINT COUNTIES LUNATIC ASYLUM.—Second Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board and lodging.

CHESHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Two Assistants to the Medical Officer of Health. Salary in each case £350 per annum and travelling expenses.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Physician to Out-patients.

CUMBERLAND, COUNTY COUNCIL OF.—Medical Officer of Health. Salary £700 per annum.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—House Surgeon, also Assistant House Surgeon. Salaries £80 and £40 respectively, with board and lodging.

EDINBURGH DISTRICT ASYLUM, Bangour Village.—Second Assistant Physician, unmarried. Salary £120, with board, apartments, and laundry.

EGYPTIAN GOVERNMENT, KASR EL AINY HOSPITAL.—Resident Surgical Officer. Salary £250 per annum, with quarters, servants, washing, coal, and light.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Surgeon for six months. Also House Physician for nine months.

EXETER, CITY AND COUNTY OF THE CITY OF.—School Medical Officer. Salary £250 per annum, rising to £300.

GLASGOW, ROYAL SAMARITAN HOSPITAL FOR WOMEN.—Visiting Surgeon.

HÔPITAL FRANÇAIS, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer. Salary £50 per annum, with board and lodging. Also Third Physician to Out-patients.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

INFANTS HOSPITAL, Vincent-square, Westminster.—Assistant Physician.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer, unmarried. Salary £80 per annum, with board and residence, &c.

LANARK, MIDDLE WARD ISOLATION HOSPITAL.—Resident Physician. Salary £150 per annum, with board, &c.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—House Surgeon for six months. Salary at rate of £50 per annum, with board, &c.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with residence and board.

LOWESTOFT HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing allowance.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES, Manchester.—Assistant Medical Officer. Salary £100 per annum.

MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL, Cheadle.—Resident Medical Officer, unmarried. Salary £150, per annum, with board and residence.

MANCHESTER, UNIVERSITY OF.—Senior Demonstrator in Physiology. Salary £150, rising to £200 per annum.

NEWCASTLE-ON-TYNE, HOSPITAL FOR SICK CHILDREN.—Honorary Surgeon.

NORTHAMPTONSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—School Medical Officer. Salary £300 per annum and travelling expenses.

FINAL EXAMINATION IN MEDICINE.

Part II., Midwifery.—James P. S. Dunn, Charles W. Laird, David J. Miller, David G. Madill, Arthur H. Laird, Alexander K. Cosgrave, James F. Clarke, Norman P. Jewell, Edward J. H. Garstin, Richard J. Attridge, Frederick R. Sayers, John C. Baker, William H. L. M'Carthy, and Alexander S. M. Winder.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Robert G Ball, Elias H. Hughes, Antonio C. Rodellnghuys, and Robert A. G. Elliott.
Botany and Zoology—Ralph J. R. Mecredy, Francis Healy, George B. Hadden, Geoffrey A. Hoffman, Francis V. Agnew, Edgar Ll. F. Nash, and Robert Tivy.

PREVIOUS DENTAL EXAMINATION.

Materia Medica.—George Elliott.
Anatomy and Institutes of Medicine.—Arthur A. Smith.
Physics and Chemistry.—Maurice Horan.

Medical Magistrates.—The names of Mr. Eleazar Davies, L.R.C.P., L.R.C.S. Edin., of Fochriw, and of Mr. Ivor Henry Davies, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., have been placed on the commission of the peace for the county of Glamorgan.

Medical Inspection of School Children.—At a meeting of the Exeter city council held on March 25th it was decided to appoint for the inspection of the school children a medical officer who should devote his whole time to the duties, the salary to be £250 per annum, increasing to £300. A proposal that three local medical men should be appointed at a salary of £60 per annum each was defeated.

Longevity.—Mrs. M. Honychurch of Anerley, London, has recently celebrated the hundredth anniversary of her birthday. She was born in Bristol on March 7th, 1808, and her birth is entered in the register at St. Thomas's Church in that city.—It is announced that Mr. Jeremiah Simmons of 25, Roundhill-crescent, Brighton, attained his hundredth year on March 21st. The Rev. J. P. Bacon-Phillips of Crowhurst Rectory, Sussex, has given some details of his life in a letter to the *Times* of March 18th. Mr. Simmons, who has been a gardener, was born at Lewes and was baptised at Fletching.—Mrs. Jane Howes Smith of Walsall, who was born on March 29th, 1806, died on March 16th. The *Times* of March 23rd mentions that she was the mother of the Rev. F. Smith, the present rector of Church Lench, Evesham.

Literary Intelligence.—The editors of the *Journal of Hygiene* have announced the publication of a supplementary journal under the title of *Parasitology*, which will be issued at intervals determined by the material received by the editors and which will form a volume of from 400 to 500 pages with plates and figures, to be issued annually. This step has been necessitated by the remarkable development of parasitology in recent years and the journal will provide a means for the publication of papers relating to all pathogenic and disease-producing parasites. The first number will contain a paper by Dr. K. Jordan and the Hon. N. C. Rothschild, entitled "Revision of the Non-combed Eyed Siphonaptera." The editors of the journal will be Professor G. H. F. Nuttall, F.R.S., and Professor A. E. Shipley, F.R.S. Papers for publication should be sent to the former at 3, Cranmer-road, Cambridge; other communications to the University Press, Cambridge. The subscription will be £1 1*s.* per volume, or 15*s.* to subscribers to the *Journal of Hygiene.*

Leicester Infirmary.—The 135th annual report of the Leicester Infirmary shows that there has been a pressure on its beds during 1907 which it is hoped has been relieved materially by the opening of the new wing in November last. The report states—

> With 171 beds available during the year, the daily number of beds occupied has been 178·5, figures which will more than all else show to what straits the honorary medical staff were put to provide for really serious cases. The number of patients passing through each bed was 18, a record which no hospital in the kingdom would wish to emulate.

In all 3014 patients have been admitted. The average cost per occupied bed was £75 5*s.* 4*d.*, the average cost per patient £4 8*s.* 2*d.*, and the average cost per patient per week £1 9*s.* 9*d.* The out-patients' department has dealt with 10,947 new patients and 29,076 old patients, making a total of 40,023 attendances. The system of inquiry into the means of applicants has been continued throughout the year and several cases have, on financial grounds, been deemed unsuitable for treatment. In the casualty department 13,619 new cases have received treatment, and the total number of attendances has been 46,697. In several cases patients who admittedly only attended for prompt treatment or were taken to the infirmary as the most accessible place for treatment were referred for subsequent care to their medical advisers. The ordinary income for the year was £16,776 and the extraordinary income £2070, a total income of £18,846. The expenditure was £16,172.

Donations and Bequests.—Mr. George Prentiss Shepherd of Keymer, Sussex, a former resident of Guildford, has offered £10,000 to build and endow a convalescent home in connexion with the Royal Surrey County Hospital.—By the will of Mr. John Waite the following hospitals will each receive £500—viz., the Hospital for Women, Shaw-street, Liverpool; the Royal Infirmary, Liverpool; the Northern Hospital, Liverpool; the Southern Hospital, Liverpool; the Consumption Hospital, Liverpool; the Children's Infirmary, Liverpool; and the Eye and Ear Infirmary, Liverpool.

British Lying-in Hospital.—The annual general meeting of the supporters of the British Lying-in Hospital, Endell-street, London, W.C., was held on March 24th, Mr. C. E. Farmer, chairman of the hospital, presiding. In moving the adoption of the report the chairman said that the in-patients had amounted to no less than 602, an increase of 87 on 1906 and far and away the largest number ever cared for in the hospital in one year. The number of out-patients had also increased from 802 to 928. Two deaths only had occurred in the hospital during the year. He added that the hospital had had the misfortune to lose during the year the services of the matron and the assistant matron, Miss Knott and Miss Sanderson, but that their successors were giving every satisfaction. The appointment of a resident medical officer had also proved a useful innovation. The income and expenditure account showed that the hospital was worked at a loss of over £500, though the deficit was made good by the receipts of a bazaar.

Medical Sickness and Accident Society.—The usual monthly meeting of the executive committee of this society was held at 6, Catherine-street, Strand, London, W.C., on March 20th. There were present Dr. F. de Havilland-Hall (in the chair), Mr. J. Brindley James, Mr. F. S. Edwards, Mr. W. Thomas (Birmingham), Dr. F. J. Allan, Dr. M. Greenwood, Dr. J. W. Hunt, Mr. J. F. Colyer, Dr. F. S. Palmer, Dr. W. Knowsley Sibley, Dr. St. Clair B. Shadwell, and Dr. J. B. Ball. The committee examined a long list of sickness claims, the majority of which have been caused by the epidemic of influenza. These claims are, for the most part, of short duration, and as there is reason to hope that the epidemic is subsiding the amount disbursed in sickness pay will have no appreciable effect on the ample reserves of the society. The number of new members joining is very satisfactory; the new entrants of this year exceed the number obtained in any previous two months of the society's working. Prospectuses and all further particulars can be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, W.C.

Royal College of Surgeons in Ireland.—The following is the list of prizes awarded for the winter session, 1907–08:—Descriptive anatomy: Junior: J. Prendiville, first prize (£2) and medal; and A. G. Mosbery, second prize (£1) and certificate. Senior: J. T. Duncan, first prize (£2) and medal; and P. J. Wigoder, second prize (£1) and certificate. Practical anatomy: *First year:* V. J. White, first prize (£2) and medal; and I. M. Swanepoel, second prize (£1) and certificate. *Second year:* T. M. Thomson, first prize (£2) and medal; and F. W. Warren, second prize (£1) and certificate. *Practice of medicine:* R. Adams, first prize (£2) and medal; and J. Meuton and Miss C. F. Williamson (equal), *second prize* (£1) and certificate. Surgery: R. Adams, first prize (£2) and medal; and G. O. Sneyd, second prize (£1) and certificate. Midwifery: J. Meuton, first prize (£2) and medal; and Miss I. M. Clarke and Miss C. F. Williamson (equal), second prize (£1) and certificate. Physiology: J. T. Duncan, first prize (£2) and medal; and F. W. Warren, second prize (£1) and certificate. Chemistry: T. P. Roberts, first prize (£2) and medal; and M. J. Hillery, second prize (£1) and certificate. Pathology: J. S. Pegum, first prize (£2) and medal; and H. R. Tighe, second prize (£1) and certificate. Physics: M. J. Hillery, first prize (£2) and medal; and T. D. Condell, second prize (£1) and certificate. The summer session commenced on April 1st, with the following lectures and practical courses:

Macmillan Company, The, New York. (Macmillan and Co., Limited, London.)

Newcastle-on-Tyne, Hospital for Sick Children.—Honorary Surgeon.

Northamptonshire County Council Education Committee.—School Medical Officer. Salary £300 per annum and travelling expenses.

to China, under Section 26 of the Transvaal Ordinance, 1904, on account of disease and physical infirmity; and how far the effect of this section had been taken into account in arriving at the comparative rates of mortality of the Chinese and Kaffirs working in the gold mines.—Mr. CHURCHILL said in reply: I understand that the total number of Chinese repatriated up to date as physically unfit is 4783. The figures of mortality show only deaths on the Rand, and deaths either of Chinese or Kaffirs who have left the Rand are not included.

Sanitary Administration in Seaside Resorts.

Mr. COURTHOPE asked the President of the Local Government Board whether, in the case of the sanitary authorities of popular seaside and health resorts who have applied for orders under the Public Health Act, 1907, he would issue such orders without delay, in order that the sanitary authorities in question might secure the advantages of the Act before the summer season commenced.—Mr. BURNS (by written answer) replied: I am desirous that the several cases should be dealt with as early as practicable and I will bear in mind the point to which the honourable Member refers; but the preliminary investigations necessary in each individual case, as well as the statutory requirements which have to be complied with, make it impossible to issue the orders with great rapidity.

MONDAY, MARCH 30TH.

Anthrax and Glanders in Human Beings.

Mr. LAURENCE HARDY asked the President of the Local Government Board whether his attention had been called to the report of the inquest on James Shaw in the City Coroner's Court on Feb. 6th; and whether he would take steps to extend the provisions with regard to the compulsory notification of disease to all cases of anthrax in human beings arising from any cause and to all case of glanders in human beings, or of suspected glanders.—Mr. BURNS answered: My attention has been called to the report of the inquest referred to. It is competent for a sanitary authority, with the consent of the Local Government Board, to make cases of anthrax and glanders in man compulsorily notifiable in their district. I may, however, state that glanders is a rare disease as regards human beings. Cases of anthrax in man chiefly occur in factories and workshops, and as regards these cases arrangements are made by the Secretary of State for information of them being given to the local medical officer of health.

The Notification of Births Act.

Mr. ALDEN asked the President of the Local Government Board whether he could state the number of county boroughs, urban district councils, and other local authorities which had adopted the Notification of Births Act; and whether he could make any statement as to the measures that had already been taken by the large industrial centres of population.—Mr. BURNS answered: The Act has been adopted by 132 local authorities. In most of the districts in which it has been adopted there is one or more female health visitors, whose duty it is in appropriate cases to visit and advise the mothers of newly born infants, and in some instances the local authority avails itself of the coöperation of local voluntary associations. In all cases the health visitors act under the supervision of the medical officer of health.

TUESDAY, MARCH 31ST.

A Case of Anthrax.

Mr. JOWETT asked the Secretary of State for the Home Department whether his attention had been called to the death, on March 8th, of a man named Michael Quigley of Bradford from anthrax, contracted whilst handling dirty cheap foreign wool for Messrs. Campbell and Harrison, woolcombers, of Shipley; if he was aware that the wool in its dusty state was thrown down to Quigley from the room above through a trap-door; and what steps he was taking to protect working people whose anxiety to earn a livelihood forced them to work under such dangerous conditions.—Mr. GLADSTONE replied: I have received a report of this case, from which it appears that the wool after opening was sent down a shoot for blending purposes in the room below, but that the whole of it had been opened over a fan in order to remove dust and dirt, and that in order still further to reduce the risk from dust the shoot is provided with swing-doors half way down which break the fall of the material. I am informed that the regulations are fully observed at the factory and that the firm are voluntarily observing additional precautions, including the provision of respirators, the opening of all material over the opening boards, and the washing of all material in a disinfectant liquid. I am causing further inquiry to be made as to whether any additional measures can be taken to reduce the danger at the blending heap.

Opium and Fever in India.

Mr. REES asked the Secretary of State for India whether, in view of the fact that the mortality from fever in India was so greatly in excess of that occasioned by other diseases, and of the fact that opium was a recognised specific, and an absolute necessity to certain races and tribes of Indians, for the treatment of this disease, he would in arrangements that were made for reducing the cultivation of opium, safeguard the supply of sufficient quantities for use for medicinal purposes.—Mr. MORLEY replied (by written answer): I have no doubt that in any further regulations which the Government of India may make for the restriction of the opium habit in India the special circumstances of particular tribes or races, necessitating a supply of the drug for medicinal purposes, will receive due consideration.

The Administration of Anæsthetics.

Mr. BRAMSDON asked the Secretary of State for the Home Department to state how many deaths occurred during the year 1907 in the metropolitan area and in the other parts of England and Wales respectively from the effects of the administration of anæsthetics.—Mr. GLADSTONE replied (in a written answer): The figures for the year 1907 are not yet available. According to the verdicts of coroners' juries and the certificates of medical practitioners, there were in the year 1906 64 deaths in London and 119 in the remainder of England and Wales caused by anæsthetics administered for operations. There appears to be some reason to doubt whether the certificates on which these returns are based are in all cases complete, and there must necessarily sometimes be difficulty in determining if death under an anæsthetic is caused by the anæsthetic. I propose therefore to make further inquiry into the matter.

BOOKS, ETC., RECEIVED.

BRAITHWAITE'S RETROSPECT.

To the Editor of THE LANCET.

SIR,—I have four volumes of "Braithwaite's Retrospect," July to December, 1850; January to June, 1851; July to December, 1851; January to June, 1853. They are almost perfect, many leaves being uncut. Can any of your readers tell me if these books are of any value?

I am, Sir, yours faithfully,
March 27th, 1908. A. B. C.

◆

Consistency.—The warning notice does not, and is not intended to, constitute an injunction to our readers to boycott the appointment. The notice means, as we have explained previously, that intending applicants should make certain inquiries. There are some appointments which we do not allow to be advertised; there are others where, the apparent difficulty having been explained to us, we permit the advertisement to appear—usually in discharge of what we conceive to be a public duty; there is a third class where we think that intending applicants ought to hear of circumstances that may induce them not to apply. The appointment in question belongs to the third class. We wish in dealing with this difficult subject that it was as easy to act always, and regardless of circumstances, upon one plan as it is to assume the title of "Consistency." But we think our reader's criticism a very just one.

Higher Standard.—We have seen the paragraph in question and we agree with our correspondent that such publicity is unfortunate.

J. O. D.—We propose to publish in an early issue of THE LANCET a little summary of what is known on the subject.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

Specimens:
- Dr. Herbert Spencer: An Ovarian Tumour with Adherent Intestine necessitating Enterectomy.
- Mr. Alban Doran: A Specimen of Hæmatosalpinx which had caused Acute Symptoms, following Retroversion of the Fibroid Uterus.

Short Communications:
- Dr. Macnaughton-Jones: A Case of Salpingo-ovaritis following Labour in a Patient previously operated upon for Tuberculous Pyosalpinx (with specimen).
- Dr. Kedarnath Das: Three Cases of Cæsarean Hysterectomy for Atresia of the Vagina, Two of them Complicated with Irreparable Vesico-vaginal Fistulæ.
- Dr. Nepean Longridge: On Creatinin Excretion in Lying-in Women.

Paper:
- Dr. Herbert Williamson and Dr. Eardley Holland: A Case of Intra-Uterine Death of the Fœtus occurring in Six Consecutive Pregnancies, with Observations upon the Importance of the Examination of the Fœtal Tissues for the Presence of the Spirochæta Pallida.

FRIDAY.

At 4.45 P.M.:

GENERAL MEETING OF FELLOWS OF THE SOCIETY.

Ballot for New Fellows.

CLINICAL SECTION (Hon. Secretaries—A. E. Garrod, Raymond Johnson): at 8.30 P.M.

Cases:
- Dr. L. Guthrie and Mr. M. S. Mayou: Right Hemiplegia with Optic Atrophy.
- Mr. Charters Symonds: A Patient Three Years after Complete Extirpation of the Larynx, showing an Improved Method of Speaking.
- Mr. W. S. Handley: Lymphangioplasty for the Brawny Arm of Cancer.
- Dr. Francis Hawkins: Ascites Treated by Paracentesis performed 25 times in 15 Months, Patient well Seven Years Later.
- Dr. F. Parkes Weber: Hæmangiectatic Hypertrophy of the Foot, possibly of Spinal Origin.
- Mr. C. H. Fagge: Rupture of External Popliteal Nerve.
- Dr. Norman Moore: Myxœdema with Optic Atrophy.
- Dr. David Walsh: Pseudo-acromegaly.
- Dr. J. Barnes Burt: Three Cases of Gout showing Destructive Changes in Bone.
- Dr. F. Parkes Weber: Acute Œdema of Hands and Feet with Pulmonary Affection.

The Cases will be in attendance at 8 p.m.

Report of Committee:
- On Dr. W. Essex Wynter's case of Methæmoglobinæmia.

Short Papers:
- Dr. J. Graham Forbes and Dr. F. Langmead: Fatal Lymphocythæmia in Early Life.
- Dr. Francis Hawkins: A Case of Multiple Rheumatic Nodules in an Adult.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

THURSDAY.—8.30 P.M., Capt. W. Salisbury-Sharpe, R.A.M.C.(V.): Diseases likely to occur on Mobilization of a Territorial Army.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-Street, Russell-square, W.C.

FRIDAY.—7.30 P.M., Dr. F. E. Fremantle: The Garden City, Rural Housing, and the Government.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Annual Discussion on Rheumatism (opened by Dr. F. Taylor). Dr. Poynton and Dr. Horder will speak on the Bacteriological Aspects of Rheumatism and Mr. Luff on the Irregular Manifestations of Rheumatism and their Treatment.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Tichborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Mr. L. B. Rawling: The Surgical Treatment of the Incompletely Descended Testis. Clinical Cases will also be shown.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN, 11, Chandos street, Cavendish-square, W.

FRIDAY.—5 P.M., Mr. H. Lett: Intussusception associated with Severe Purpura. Mr. J. P. Parkinson: Tetanus Neonatorum. Mr. G. Pernet, Mr. L. Guthrie, Dr. G. Carpenter, Mr. P. Parkinson, and others: Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M. Lecture:—Dr. H. Walsham: The X Rays in the Diagnosis of Diseases of the Chest.

TUESDAY.—4 P.M., Dr. W. Carr: Clinique (Medical). 5.15 P.M. Lecture:—Dr. C. O. Hawthorne: The Clinical Anatomy and Physiology of the Nervous System.

WEDNESDAY.—4 P.M., Mr. J. Cantlie: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. C. O. Hawthorne: The Clinical Anatomy and Physiology of the Nervous System.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. G. Oliver (Harrogate): Recent Studies in Arterio-sclerosis.

FRIDAY.—4 P.M., Mr. R. F. Pickerton: Clinique (Eye).

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon, also Assistant House Physician. Salary in each case £60 per annum, with board, lodging, and washing.

PRESTON, LANCASHIRE EDUCATION COMMITTEE.—School Medical Superintendent. Salary £500 per annum, rising to £650, with expenses.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, London, N.—House Surgeon and House Physician; also Junior House Surgeon and Junior House Physician. All for six months. Salary of two former at rate of £75 per annum, and of two latter at rate of £40 per annum, with board, residence, and laundry.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Resident House Physician and Resident House Surgeon. Board, &c., provided.

ROYAL NAVY, MEDICAL DEPARTMENT.—Examination for not less than 15 Commissions.

SALFORD ROYAL HOSPITAL.—Honorary Surgeon for the Pendleton Branch Dispensary.

SHEFFIELD EDUCATION COMMITTEE.—Assistant Medical Officer. Salary £250 per annum, rising to £300.

SHREWSBURY, SALOP INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

SINGAPORE, STRAITS SETTLEMENTS, MUNICIPAL HEALTH DEPARTMENT.—Assistant Municipal Health Officer, unmarried. Salary $4200, rising to $4300.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Honorary Assistant Physician.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried, for six months, renewable. Salary at rate of £70 per annum, with residence, board, and washing.

SOUTH UIST (Southern Division).—Medical Officer. Salary £77 10s.

STIRLING DISTRICT ASYLUM, near Larbert.—Medical Superintendent. Salary £700 per annum, with house, &c.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—House Physician. Salary £100 per annum, with apartments, board, and washing.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

TOXTETH PARK WORKHOUSE AND INFIRMARY.—Assistant Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea.—House Surgeon for six months. Salary £50, with board, lodging, and laundry.

WALSALL EDUCATION COMMITTEE FOR THE COUNTY BOROUGH.—School Medical Officer. Salary £200 per annum.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Honorary Registrar and Pathologist.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

WORCESTER GENERAL INFIRMARY.—House Surgeon. Salary £80 per annum, with board, *residence*, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Manchester (East), in the county of Lancaster.

Births, Marriages, and Deaths.

BIRTHS.

BEST.—On March 30th, at Ilford, Essex, the wife of W. Harris Best L.R.C.P. Lond., of a son.

BROWN.—On March 25th, at Bartholomew-road, N.W., the wife of Alexander Brown, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

GREGORY.—On March 31st, at Apiti, New Zealand, the wife of Charles H. Gregory, M.A., M.B., B.C., M.R.C.S., L.R.C.P., of a daughter.

MENDES.—On March 27th, at the County Asylum, Cheddleton, Staffordshire, the wife of William Francis Mendes, M.D., M.R.C.P., of a daughter.

WALKER.—On March 27th, at Oakfield-road, Clifton, Bristol, the wife of Cyril H. Walker, M.B., of twins (boy and girl).

MARRIAGES.

BEADNELL—SHELDON.—On March 28th, at St. Andrew's Church, Worthing, Captain Herbert Owen Marsh Beadnell, R.A.M.C., to Mabel, only daughter of John Sheldon, Esq., of Tilehurst, Reading.

THOMSON—FRIPP.—On March 28th, at St. George's, Hanover-square, J. Marshall Thomson, L.D.S. R.C.S. Edin., to Alice Edith, daughter of John Trude Fripp, L.D.S. R.C.S.

DEATH.

WOOD.—On March 13th, at Middleton, Driffield, East Yorkshire, William Wood, M.R.C.S. Eng., L.S.A. Lond.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE BONESETTER IN THE SEVENTEENTH CENTURY.

THE bonesetter is not an invention of to-day: he seems to have flourished at a time when there was no course of medical studies made imperative upon the medical man. A correspondent has pointed out to us that Sir John Bramston in his autobiography tells how his boy Anthony rode out setting with a dog at Skreens in Essex in 1687 and was thrown so that he put his right shoulder out of joint, when a bonesetter, one Mr. Strut of Chelmsford, "tryed it with a coole-staff," which put Anthony to extreme torture. It seems that the men who were holding the patient let go. Strut tried again with his foot but the kicks of Anthony injured the operator, and "after being four times tormented" Anthony's bone was still out. One Pesgrave of London was then accounted the best bonesetter of England, but to him a local man, Mr. Hastler of Bishop's Stortford, was preferred. "Can you doe it at once," said the poor boy, who, says our correspondent, preferred being a cripple for life to being so much tortured again. Hastler said, "Yes, or never." Anthony was laid on his back and what happened is thus described: "A towel was put under his arm-hole but upon a bolster, and round the neck of the operator: three men held the lad by his other arm and his leggs, and all pulling hard at once Strut with his foot put the bone in its place, which gave a snap that all heard it;" ...... "for which God be praised," says Sir John Bramston.

LIFE INSURANCE COMPANIES MEDICAL FEES.

To the Editor of THE LANCET.

SIR,—I have felt for a long time that the various life insurance companies pay their medical examiners very inadequate fees. These companies are wealthy and their directors are handsomely paid, yet they expect a medical man to most carefully examine the life to be insured and in addition to make a very critical analysis for the absurd remuneration of 10s. 6d., and if the person insures for a large sum then a guinea is paid. It is quite time the medical profession bestirred itself and refused to continue on these terms. A guinea is the lowest fee that ought to be offered, rising to 3 guineas according to the sum insured.

I am, Sir, yours faithfully,

Windsor, March 22nd, 1908. WILLIAM FAIRBANK.

*** A great many medical men refuse to take less than a guinea and we think their action very reasonable.—ED. L.

A MEDICAL WOMAN AS A SUFFRAGIST.

WHATEVER views may be held with regard to the desire of some women to obtain the suffrage it is difficult to sympathise with the tactics of the passive resister as exemplified by Miss O. M. S. Lewin, M.B., B.S., who recently refused to pay a guinea for a licence to use armorial bearings. Still, it was unkind of Mr. Plowden, in fining Miss Lewin £10, to say to her, "Consider your crest lowered"—joking against any individual who cannot joke back is to be deprecated. By the way, heraldic experts are probably rather amused at this case. Miss Lewin supplied evidence with regard to the possession of a crest so that it should be clear that she was breaking the law. As a matter of fact, a woman has no crest—armorial bearings seem to have been in question but what Miss Lewin pleaded guilty to using was "her crest." A woman in certain circumstances has an armorial coat but she has no crest. So the law is making Miss Lewin pay for the privilege of using what she has not got, except in the general sense that all armorial devices are taxable, and Miss Lewin, to make sure that it should be quite clear that she is a passive resister, supplies evidence to prove her possession of what she cannot have.

A BAD STARTER.

To the Editor of THE LANCET.

SIR,—A lad of 18, of steady habits and of good general knowledge, with a public school education, has been up three times at the College of Preceptors for the entrance medical examination. He gets excellent marks for classics, history, and geography, but fails each time in mathematics. For this subject he has no capacity. Can you advise me in the matter? Is there an examining body less exacting in this subject, or do you recommend the abandonment of the profession for a boy who cannot do geometry.

I am, Sir, yours faithfully,

March 30th, 1908. ANXIOUS GUARDIAN.

*** We should certainly encourage the lad to persist as he has been invariably successful in the other subjects. He has probably been taught mathematics badly and does not approach mathematical questions in any right method. We recommend a "coach." There is no way into the medical profession which does not require the acquisition of elementary mathematics, but the amount is small, and a properly taught lad should be able to master it easily if he shows intelligence in other directions.—ED. L.

BIRTHS.

Best.—On March 30th, at Ilford, Essex, the wife of W. Harris Best L.R.C.P. Lond., of a son.

Brown.—On March 25th, at Bartholomew-road, N.W., the wife of Alexander Brown, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

Gregory.—On March 31st, at Apiti, New Zealand, the wife of Charles H. Gregory, M.A., M.B., B.C., M.R.C.S., L.R.C.P., of a daughter.

Menzies.—On March 27th, at the County Asylum, Cheddleton, Staffordshire, the wife of William Francis Menzies, M.D., M.R.C.P., of a daughter.

Walker.—On March 27th, at Oakfield-road, Clifton, Bristol, the wife of Cyril H. Walker, M.B., of twins (boy and girl).

MARRIAGES.

Beadnell—Sheldon.—On March 25th, at St. Andrew's Church, Worthing, Captain Herbert Owen Marsh Beadnell, R.A.M.C., to Mabel, only daughter of John Sheldon, Esq., of Tilehurst, Reading.

Thomson—Fripp.—On March 23th, at St. George's, Hanover-square, J. Marshall Thomson, L.D.S. R.C.S. Edin., to Alice Edith, daughter of John Trude Fripp, L.D.S. R.C.S.

DEATH.

Wood.—On March 13th, at Middleton, Driffield, East Yorkshire, William Wood, M.R.C.S. Eng., L.S.A. Lond.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE BONESETTER IN THE SEVENTEENTH CENTURY.

The bonesetter is not an invention of to-day; he seems to have flourished at a time when there was *no* course of medical studies made imperative upon the medical man. A correspondent has pointed out to us that Sir John Bramston in his autobiography tells how his boy Anthony rode out setting with a dog at Skreens in Essex in 1657 and was thrown so that he put his right shoulder out of joint, when a bonesetter, one Mr. Strut of Chelmsford, "tryed it with a coole-staff," which put Anthony to extreme torture. It seems that the men who were holding the patient let go. Strut tried again with his foot but the kicks of Anthony injured the operator, and "after being *four times tormented*" Anthony's bone was still out. One Pesgrave of London was then accounted the best bonesettor of England, but to him a *local* man, Mr. Hastler of Bishop's Stortford, was preferred. "Can you doo it at once," said the poor boy, who, says our correspondent, preferred being a cripple for life to being so much tortured again. Hastler said, "Yes, or never." Anthony was laid on his back and what happened is thus described: "A towel was put under his arm-hole but upon a bolster, and round the neck of the operator: three men held the lad by his other arm and his leggs, and all pulling hard at once Strut with *his foot* put the *bone in its place*, which gave a snap that all heard it;" ...... "for which God be praised," says Sir John Bramston.

LIFE INSURANCE COMPANIES MEDICAL FEES.

To the Editor of The Lancet.

Sir,—I have felt for a long time that the *various* life insurance companies pay their medical examiners very inadequate fees. These companies are wealthy and their directors are handsomely paid, yet they expect a medical man to most carefully examine the life to be insured and in addition to make a very critical analysis for the absurd remuneration of 10*s*. 6*d*., and if the person insures for a large sum then a guinea is paid. It is quite time the medical profession bestirred itself and refused to continue on these terms. A guinea is the lowest fee that ought to be offered, rising to 3 guineas according to the sum insured.

I am, Sir, yours faithfully,

Windsor, March 22nd, 1908. William Fairbank.

⁂ A great many medical men refuse to take less than a guinea and we think their action very reasonable.—Ed. L.

A MEDICAL WOMAN AS A SUFFRAGIST.

Whatever views may be held with regard to the desire of some women to obtain the suffrage it is difficult to sympathise with the tactics of the passive resister as exemplified by Miss O. M. S. Lewin, M.B., B.S., who recently refused to pay a guinea for a licence to use armorial bearings. Still, it was unkind of Mr. Plowden, in fining Miss Lewin £10, to *say to her*, "*Consider* your crest lowered"—joking against any individual who cannot joke back is to be deprecated. By the way, heraldic experts are probably rather amused at this case. Miss Lewin supplied evidence with regard to the possession of a crest so that it should be clear that she was breaking the law. As a matter of fact, a woman has no crest—armorial bearings seem to have been in question but what Miss Lewin pleaded guilty to using was "her crest." A woman in certain circumstances has an armorial coat but she has no crest. So the law is making Miss Lewin pay *for the privilege of* using what she has not got, except in the general sense that all armorial devices are taxable, and Miss Lewin, to make sure that it should be quite clear that she is a passive resister, supplies evidence to prove her possession of what she cannot have.

A BAD STARTER.

To the Editor of The Lancet.

Sir,—A lad of 18, of steady habits and of good general knowledge, with a public school education, has been up three times at the College of Preceptors for the entrance medical examination. He gets excellent marks for classics, history, and geography, but fails each time in mathematics. For this subject he has no capacity. Can you advise me in the matter? Is there an examining body less exacting in this subject, or do you recommend the abandonment of the profession for a boy who cannot do geometry.

I am, Sir, yours faithfully,

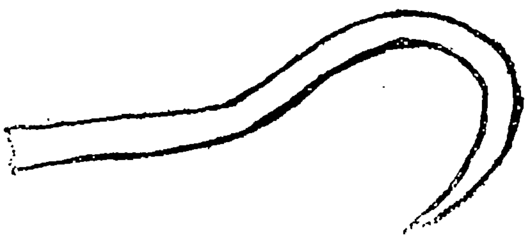
March 30th, 1908. Anxious Guardian.

⁂ We should certainly encourage the lad to persist as he has been invariably successful in the *other* subjects. He has probably been taught mathematics badly and does not approach mathematical questions in any right method. We recommend a "coach." There is no way into the medical *profession* which does not require the acquisition of elementary mathematics, but the amount is small, and a properly taught lad should be able to master it easily if he shows intelligence in other directions.—Ed. L.

having healed (I need hardly say without suppuration) the patient was allowed to leave her bed and left the hospital soon after to practise using the limb.

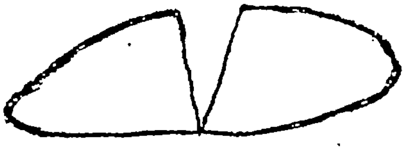
Before long she was readmitted and the second operation was performed. The lower cicatrix was opened and the wire removed and two interrupted wire sutures placed in the tracks of the previous continued one, the fragments, of course, being this time pared to clear them of fibrous tissue of new formation and produce smooth surfaces for coaptation. This was all satisfactorily effected, though not without the use of the powerful hook and the vertical position of the limb. The result was restoration of the use of the joint in a manner so satisfactory that I determined to try the same procedure in the other limb. The only difference which I made in this case was that, as the upper fragment was too small to bear drilling, I passed the ends of the wire, in dealing with that fragment, through the tendon of the quadriceps just above the upper border of the bone, the lower fragment, which was, of course, very substantial, being drilled as in the other limb. By this means, aided by the vertical position of the limb and the hook, I was able to bring down the upper fragment very satisfactorily, so much so that I did not feel it needful to have the patient use the limb in walking before proceeding to the second operation, but did this before she left her bed, soon after the wound had healed. In the second operation I applied two interrupted sutures, passing them, as in the first operation, through the track in tendon and bone which the first wire had occupied.

Fig. 4.



The continued wire suture, which was first used by Dr. Hector C. Cameron of Glasgow, has the great advantage, where much traction has to be made upon the fragments, that the pressure of the wire is distributed over the anterior surface of the bone instead of being concentrated upon the limited portion of tissue included in an interrupted stitch. And this is peculiarly valuable in old cases of fracture, in which, as a result of long disuse, the bone undergoes interstitial atrophy, that sometimes makes it very soft. But this suture has the disadvantage that it may tilt the fragments so that their anterior edges do not come well into contact with each other, as indicated in Fig .5.

Fig. 5.



This was my reason for preferring the interrupted suture in the second stage of the proceeding. In the first stage in which the principal dragging probably takes place this circumstance is a matter of no consequence, as accurate position of the fragments is not then aimed at; and in any case admitting of being dealt with by a single operation, though not without much traction, this defect of the continued suture might be readily got over by introducing a superficial central stitch of comparatively thin wire to insure coaptation of the anterior margins of the fragments.

The effect of the second operation in the above case was such as would have surprised me if I had not seen in other cases how substantial and strong a patella may result from wiring after thorough paring of the surfaces, even when one of the fragments is of quite insignificant size. Without my notes I cannot say how long it is since the case was treated, but I think it must be about four years. And I lately had the satisfaction of hearing from the patient that she could walk well, with strong and supple knee-joints.

In Miss ——'s case I would suggest that you should, in the first instance, before making any incision, but after she has been placed under an anæsthetic, apply the strong sharp hook to the border of the upper fragment through the skin, and, with the limb vertical, ascertain to what extent the quadriceps will yield immediately. If the upper fragment came pretty well down you would proceed to do all by one operation, but if there were the slightest doubt as to the feasibility of this you would adopt the preliminary procedure as in the above case.

Supposing you to be doing all by one operation and that it seems desirable to employ Cameron's continued suture, as the wire will be left in permanently, it would be better to introduce its ends first into the lower fragment and fix them over the upper one, where the fixed ends could not cause inconvenience in kneeling. The strong hook would keep the upper fragment well down during the fixing process. If I had published this case, as I ought perhaps to have done, I should not have had to inflict upon you so large an amount of manuscript. I remain,

Ever truly yours,
(Signed) Joseph Lister.

The Hunterian Lectures
ON
THE PYGMY AND NEGRO RACES OF AFRICA.

Delivered before the Royal College of Surgeons of England on March 2nd, 4th, and 6th, 1908,

By F. C. SHRUBSALL, M.A., M.D. Cantab., M.R.C.P. Lond., M.R.C.S. Eng.,
RESIDENT OFFICER OF THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, LONDON, S.W.

LECTURE II.[1]

Delivered on March 4th.

Mr. President and Gentlemen,—The greater part of Central and Southern Africa is inhabited by the negro peoples who present a greater uniformity of features than is to be found in any other area of equal size. The characters are such as to clearly distinguish them from the rest of mankind. Their skin is dark, the shade varying from a deep golden brown to an intense slate which is almost black. Their hair is black, short, and crisp, usually arranged in tight ringlets, especially at the side of the head, but it never quite forms the peppercorn clusters so characteristic of the Bushmen. Among some of the tribes of the North-Western coast it grows to a greater length and is decidedly frizzly. Their eyes are dark-brown or at the lightest yellowish. The stature presents considerable individual variations, 5 feet 8 inches being the general average. On the whole, the northern negro is taller than the southern. The upper limbs are proportionally longer than in the white races, the second finger reaching nearly to the knee when the arms are hung straight down by the side. As a result their span is also greater. The proportional length of the upper limb is from 47·5 to 48·5 per cent. of the stature of the negro, as compared with 45 per cent. in the European canon. A great part of this difference depends on the forearm, which averages from 17 to 18 per cent. in the negro as against 14 per cent. in the European. The negro also exceeds the white in the length of the lower limb but the proportion which this bears to the stature presents considerable individual and tribal variations. Sir H. H. Johnston has stated that the "mass of black negroes may be divided into the short-legged and the long-legged." Good examples of the long-legged class are the Nilotic tribes of the White Nile and the north-east coast of the Victoria Nyanza but the type appears throughout Southern Africa. "The short-legged type appears among the Lendu, the Jur of the Bahr el Ghazal, the tribes on the fringes of the Congo forest, and in West Africa among the Kru and others." In a series of measurements made in Uganda this character served to distinguish the tribes of Bantu speech from the others and the results obtained were subsequently found to coincide with other lines of evidence.

---

[1] Lecture I. was published in The Lancet of April 4th, 1908, p. 983.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Evening News and Southern Daily Mail, Westminster Gazette, The Hour Glass, Glasgow Evening Times, Aberdeen Evening Express, Bristol Mercury, South Wales Echo, East Anglian Times, Manchester Chronicle, Aberdeen Journal, Lincolnshire Echo, Sunderland Echo, Glasgow Evening Citizen, South Wales Daily News, Midland Weekly News, Law Times, Yorkshire Telegraph Yorkshire Post, South Leeds Daily News, Somerset Weekly Gazette, Cheltenham Examiner, Indian Daily News, Pall Mall Gazette, Bakers' Record, &c.*

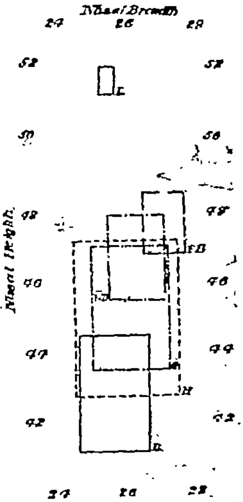
Zeriba country. These tribes appear to be of a pure negro stock. With these perhaps should be grouped the more mixed Suk-Turkana, Elgumi, Nandi, and possibly even the Masai and the Anderobo.

Central group.—The Baghirmi, Kanuri, Sonhray, and Hausa. These tribes are largely of mixed blood.

Western group.—The Fulah and Wolof, of mixed origin; the Mandingo, many of whom are of mixed ancestry; the Kru and Vai, among whom individuals show traces of a distant racial intermixture; and the Tshi (Ashanti), Ewe (Dahomey), Yoruba (Benin), Mossi, and others who are the best representatives of the true negro.

The Bantu peoples do not so readily permit of classification other than by their geographical distribution. For the comparison of skulls I have adopted a provisional division into eastern and western. Observations on the living are available from German East Africa, the Middle Congo, and Uganda, which will be referred to by name. The main division is between the Bantu and the Soudanese who offer contrasts not only in language but in many features of culture. The distinctions drawn by Haddon, Keane, and others apply more to the Western Soudanese and the Southern Bantu than in general; moreover, some degree of overlap occurs along the boundaries. Broadly, the negro culture may be described as agricultural though in places stock raising is also carried on, especially in the Central Soudan and among the Bantu of the south and east. It has been suggested that this is due to Hamitic influence, but it seems also to depend in large measure on the suitability of the country for pasturage and on the occurrence or otherwise of raiders. The manufacture of pottery, carving, and metallurgy are common arts, though certain tribes exhibit special skill.

FIG. 4.



Areas showing relation as to nasal height and breadth.

Soudanese.		*Bantu.*
Huts.—Gable roofed.	...	Rounded with pointed roofs.
Spears.—With socketed heads.	...	Fastened to shaft by a spike.
Bow-strings.—Vegetable fibre.	...	Animal fibre.
Weapons.—Swords, plaited shields; no clubs.	...	Clubs, skin or wooden shields.
Clothing and ornaments.—Of vegetable origin.	...	Of animal origin.

In the west fetishism is very highly developed, masks are common, and secret societies are frequent; in the south and east ancestor worship is prevalent, fetishism is undeveloped, and there are said to be no secret societies. These linguistic and cultural distinctions being established, it seemed important to endeavour to determine how far they were accompanied by differences in physique, also how far such differences if found are to be ascribed to racial intermixture. The materials available for this purpose consist of measurements of the living made by various observers and of the skulls and skeletons in European museums; and lastly, the comparison of typical photographs. These may be considered in order. The measurements of the living are unfortunately few in number and in most cases have included a very small selection of characters. The stature shows no very characteristic features.

Western Soudanese.	Mm.	ft. in.
Sierra Leone ...	1735	= 5 8½
Lagos	1800	= 5 10½
Old Calabar ...	1715	= 5 7½
Guinea Coast ...	1724	= 5 7¾
Eastern Soudanese.		
Nilotic Negroes	1800	= 5 10¾
Zandeh	1725	= 5 8

Central Soudanese.	Mm.	ft. in.
North Nigeria...	1697	= 5 6¾
M'Zab (slaves)...	1620	
Bantu.		
Uganda	1715	= 5 7½
Nyassaland... ...	1730	= 5 8
Congo...	1710	= 5 7¼
Bechuana	1685	= 5 6¼
Zulu	1710	= 5 7¼

The cephalic index yields similar insignificant results.

Western Soudanese.	
Sierra Leone	75·9
Lagos...	75·3
Old Calabar	73·3
Ashanti	75·0
Eastern Soudanese.	
Nilotic Negroes	77·7

Central Soudanese.	
North Nigeria	76·4
M'Zab (slaves)	74·2
Bantu.	
Uganda	75·6
Congo	75·4
Nyassa	75·0
South-East Africa	74·8

Better results follow the percentage classification of this index under three heads, representing long, medium, and broad skulls.

—	Dolicho-cephalic.	Mesati-cephalic.	Brachy-cephalic.
	Per cent.	Per cent.	Per cent.
Bantu—			
North Nyassaland	40·1	51·9	8·0
Unyamwesi, &c.	54·0	39·5	6·5
Uganda	60·8	35·8	3·5
Middle Congo	59·0	38·0	3·0
Western Soudanese	80·0	20·0	—

The table shows the greater frequency of broad heads among the southern people. The numbers in every case are so small as to render statistical treatment of little avail. It is particularly unfortunate that very few measurements have been made on the living Western and Central Soudanese. Further investigations have been made on the peoples of Uganda, of German East Africa, and of the Middle Congo by Sir H. H. Johnston, Count Schweinitz, and Mense, which I have summarised in an appendix to the former author's "Uganda Protectorate." From this it would appear that the nose is broad and flat among all the tribes of East Central Africa with the exception of the Bahima and the Masai, in whom it is more prominent and more arched. The nasal index, or the percentage relation of the breadth between the alæ to the height from the root of the nose to the septum, affords a rough basis for classification. The broadest noses occur among the pygmy tribes of the forest zone and those taller tribes in direct contact with them. The Nilotic negroes have lower indices and therefore narrower noses than the Bantu negroes, such as the Baganda, the Kavirondo, the Wanyamwesi, and other tribes between the Great Lakes and the Indian Ocean. There is, however, a band of tribes, among whom many individuals present narrow nasal orifices, stretching along the higher ground from the west of Lake Victoria and midway between Lake Tanganyika and the sea. These include the Bahima, Basoga, Watuta, Wagogo, and the Angoni, who link up with the Kaffir tribes of South Africa among whom these features also appear. The eastern group of tribes comprising the Suk-Turkana, Nandi, Andorobo, Masai, &c., also presents lower indices than does either the Nilotic negro or the first-mentioned group of Bantu. If it be remembered that the adjacent Hamitic peoples, whether Galla, Somali, or Abyssinian, have narrower noses, it will be seen that this affords some evidence of racial intermixture spreading from the north-east. The proportions of the various segments of the body afford similar evidence, the Bantu peoples of Uganda being characterised by relatively longer arms, shorter legs, and longer trunks than the Nilotic negroes or the tribes of the eastern plateau. In these characters they resemble the pygmies and to a less degree the Bushmen-Hottentots which might well be due to some mixed strain of blood if these Lake Bantu tribes represent the first invaders of the territory of the former groups. The type with the narrower nasal orifices is also characterised by

Remarks ON THE TREATMENT OF FRACTURES OF THE PATELLA OF LONG STANDING.

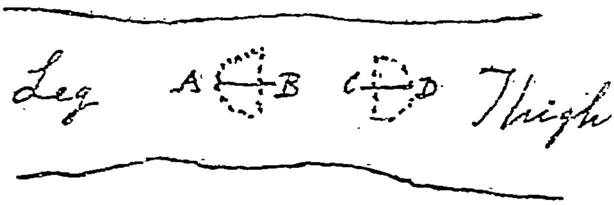
BY LORD LISTER, F.R.S.

SHORTLY before I retired from practice I devised a method of dealing with fractures of the patella of long standing which gave very satisfactory results. I failed to publish it at the time; but a surgical friend having asked my advice in a case of that kind, I wrote for him a detailed description of the procedure, preserving a copy of my letter which I venture, even at this late period, to reproduce.

Fisher's Hotel,
Pitlochry, Scotland.
September 15th, 1895.

MY DEAR DR. ——,—I should have written to you long ago regarding Miss ——'s case had I not known that you could not deal with it till you had returned home after your autumn holiday in Europe; Mr. —— having given me your address in London up to the 15th inst. The limb is no doubt useful as it is; but it is very far from being as strong as we should wish to see it; and assuming, as I do in your case, that the surgeon can look with confidence to an aseptic condition of the wound, I think an endeavour should be made to improve it. Indeed, there is good reason to believe that it will be made as serviceable as ever. I doubt, however, whether you will be able to bring the fragments together without some special mode of procedure. When you visited my wards in King's College Hospital, now several years ago, I showed you a young man on whom I had operated on account of a fracture of the patella of long standing with considerable separation of the fragments, where I had attained my object by means of free division of the quadriceps extensor muscle. This, however, is a pretty severe measure and involves, at the best, more or less weakening of the muscle and a long cicatrix.

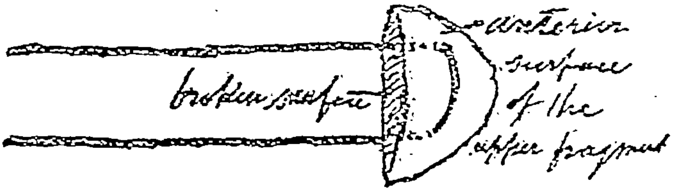
FIG. 1.



Since that time I have greatly improved on that practice and have succeeded without touching the quadriceps by proceeding in two stages. The idea was suggested to me by a case published by Dr. Lucas-Championnière of Paris who, being unable to get the fragments into apposition, wired them together nevertheless and left the wire in as an adjuvant connecting medium. It occurred to me that, although such a use of the wire did not seem likely to be very satisfactory as a permanent arrangement, yet it might probably be adopted with great advantage as a temporary expedient; and that after the quadriceps had been gradually stretched by the use of the limb in the position so produced the fragments might by a second operation be brought into contact and might then be wired in the way after paring the opposed surfaces. The first case in which I put this idea into practice was a sufficiently testing one. The patient was a young woman of very stout and heavy build who had fractured both patellæ, one of the four years and the other three years before she consulted me. The fragments were in both limbs considerably separated and in the left, where the bone had been injured four years previously, the separation was so great (about five inches) and the upper fragment at the same time so very small that I at first despaired of being able to do anything.

But on the right side, the upper fragment being of good size and the separation more moderate, I determined to give the plan a trial. I made two short longitudinal incisions (Fig. 1, A B and C D) over the two fragments (shown in dotted line), and having exposed them by a little dissection drilled two holes in the upper one, and passed through them, from without inwards, the ends of a piece of the usual stout silver wire, so that when the ends were pulled upon the middle of the loop of wire would press upon the surface of the fragment, as seen in Fig. 2. Next, passing into the lower incision a blunt instrument (a broad raspatory), I detached from the front of the femur the soft parts lying between the incisions, consisting, of course, only of skin and fat, as the muscle was absent at that part. Then passing a strong pair of forceps from the lower incision under the skin till their blades appeared in the upper incision, I seized the ends of the wire and drew them down into the lower incision. I then drilled two holes in the lower fragment and passed the ends of the wire through them from within outwards, and, after drawing the upper fragment well down, secured them in the usual way and cut the ends short. The immediate result, so far as the fragments were concerned, is indicated in Fig. 3. The incisions in the skin were then brought together by sutures and a dressing (the double cyanide gauze) applied.

FIG. 2.



In drawing down the upper fragment I found a great advantage from the use of a very strong sharp hook (Fig. 4), the point of which was inserted in the tendon of the quadriceps at its attachment. By this means I was able to exert much greater traction upon the bone than can be done by simply pulling upon the wire, and in order to relax the quadriceps as much as possible the limb was placed in the vertical position before the fragment was pulled down. The dressing having been put on, a trough of Gooch's splint was applied to the limb still in the elevated position, and the same attitude was maintained as the patient was removed to the ward, and continued by attaching the end of the splint to a rope connected with the tripod and pulley used in applying Sayre's plaster-of-Paris jacket. This position of the limb did not cause the patient material inconvenience, and after two or three days the rope was slackened a little so as to allow the end of the splint to come down an inch or two, and the same thing was repeated every two days or so till the limb could be placed quite horizontal.

This preliminary operation has taken a long time to describe, but in execution it is of the simplest character, no paring of the broken surfaces being done at this stage and there being almost no bleeding and no shock. The wound

A Clinical Lecture

ON

THE DIAGNOSIS AND TREATMENT OF MALIGNANT DISEASE OF THE PROSTATE.

Delivered at the Medical Graduates' College, London, on Feb. 3rd, 1908,

BY J. W. THOMSON WALKER, M.B. EDIN., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AT THE HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITALS; ASSISTANT SURGEON TO ST. PETER'S HOSPITAL FOR STONE.

IN a statistical study[1] of 16 cases of malignant disease of the prostate collected from the records of 6732 cases of cancer in the Middlesex Hospital I estimated that the ratio of cancer of the prostate to other forms of cancer was 2·3 per 1000. Previous writers (Tauchon, Gürlt, Heinemann) had given a less ratio. From the frequency with which cancer of the prostate is now met with in surgical practice I believe that these figures under-estimate the actual numbers. More important for the purposes of clinical diagnosis, however, is the relative frequency of malignant and simple enlargement of the prostate. In order to obtain some information on this point I have taken 242 consecutive cases of enlargement of the prostate which have passed through my hands and find that the diagnosis of malignant disease of the prostate was made in 57 cases and of simple enlargement in the remaining cases. That no possibility of cavil may exist in regard to the diagnosis, 17 of these cases have been excluded from the list and have been put under the category of "doubtful cases." The remaining 40 cases afford no opportunity for criticism. In 11 of them the diagnosis was confirmed by operation and microscopical examination and in the remaining 29 the disease was either so far advanced when the patient first came under my observation or the progress of the disease was such that the diagnosis was indisputable. This gives a proportion of 16·5 per cent. of malignant growths in the total number of cases of enlarged prostate.

I shall proceed to discuss the symptomatology of these cases and my remarks will be based entirely upon them. The average age of the 40 cases was 65 years and, as most of them applied for advice within a comparatively short time after the onset of the symptoms, this age may be taken to represent the time of life at which symptoms first appear. In one patient symptoms commenced at the age of 44 and in another at 46 years. Malignant disease of the prostate is, however, of slow growth and the symptoms which it produces are due to urethral obstruction or nerve pressure, so that the disease has spread widely before they appear. It is probable, therefore, that the growth actually commences at a much earlier age. The age is practically the same as the average age of the 185 cases of simple enlargement of the prostate, which was 66 years. Age is not, therefore, of great value in making a diagnosis, although we may suspect that an enlargement of the prostate which commences much under 50 is more likely to be malignant than simple.

Difficult micturition; retention.—Difficult micturition is the cardinal symptom of malignant disease of the prostate. It is the most frequent, the most prominent, and usually the earliest symptom. Obstruction to the outflow of urine was present to a marked degree in 37 of the 40 cases (92·5 per cent.) and it was the first symptom of disease in 22 (55 per cent.). A frequent history (22 cases, 55 per cent.) was a gradual onset of difficulty. The patient complained that he could not start passing urine promptly but had to wait a little; the stream was small and might drop down instead of being projected with force and the last part of the urine dribbled or there was some after-dribbling when the act had apparently been completed. With the gradually increasing difficulty of micturition there were in a few cases (4 cases) one or several attacks of retention and eventually the patient might become partly (7 cases) or completely (2 cases) dependent upon the catheter. In other cases (14 cases) the onset was sudden and in some of these (8 cases) there was an initial attack of complete retention. The bladder usually partly recovered its tone after this initial attack.

Frequent micturition.—Next to difficult micturition an increase in the frequency of the act is the symptom of which the patients most often complain. There was a well-marked increase in the number of times urine was passed in 35 cases (87·5 per cent.). This was the initial symptom in five cases (12·5 per cent.) and it was accompanied by pain in one other case. In only two cases was the increased frequency entirely diurnal; in all other cases the patient passed urine at intervals during the night as well. In a few of these the prostatic type of nocturnal micturition was observed; the patient rested for the first four or five hours of the night and rose at 2 or 3 o'clock and several times after this. In most cases, however, the intervals were equally spaced at three or two hours throughout the night. The frequent micturition was not due to a septic condition of the urine, for in 10 cases where no catheter or other instrument had been passed and the urine was clear diurnal and nocturnal frequency was present. In four patients there was continual dribbling from a bladder which was not distended. In only one of these was the urine foul and indicative of chronic cystitis. In the others it was either clear or slightly cloudy. The growth had spread widely in all four cases. In two it formed a large hard mass above the pubes, infiltrating the abdominal wall in one. In the other two cases it had spread up the bladder base beyond the reach of the finger. These cases, with the exception of the one with foul urine, were remarkable for the absence of bladder symptoms until the dribbling commenced. The growth seems to have spread outside the bladder along the anterior and posterior walls and so fixed the urethra that it acted as an immobile tube which drained off the urine.

Pain.—Pain was slightly less often present than the previous symptoms, being noted in 29 cases (72·5 per cent.). It was the initial symptom in ten cases.

There were three types of pain—namely, pain connected with micturition, pain apart from micturition but due to urinary obstruction, and pain independent of micturition or blockage. The pain associated with micturition was usually along the urethra and in the penis, being most marked on the under surface of the glans about the base of the frænum or on the upper surface just behind the corona. It was experienced either at the commencement of micturition or after the act. The pain was aching and not severe. Pain on micturition was perineal in one case and in another spread to the groins and shot down the legs to the soles of the feet. In three cases it was suprapubic. Aching over both kidneys resulted from urinary obstruction in three cases. More striking and characteristic was pain apart from micturition and unconnected with urinary blockage. This was observed in the penis, or urethra, or at the root of the penis or the peno-scrotal junction. In some cases the rectum was the seat of pain and in one the anus was affected. There was frequently heavy aching pain in the lower part of the spine and across the base of the sacrum, and also at the sacro-iliac synchondroses and sometimes in the hip-joints. Suprapubic pain was not uncommon; perineal pain was noted in one case. There was pain in the groins and in the legs in two cases. In one the pain was distributed over the front of the thighs as far as the knees and in another it extended down the back of the thighs. No masses of enlarged glands could be felt in the pelvis in these cases. The pain in all these cases was sufficiently severe to cause distress, but in none of them was it agonising in character. What was remarkable about it was its constant presence in a case of urinary disease, its persistence over a period of months or years, the absence of any connexion with micturition or movement, and the disappointing effect of drug treatment.

I shall outline an illustrative case. A man, aged 58 years, was sent to me by Dr. J. P. Atkinson of Saffron Walden having suffered for nine months from pain in the lower part of the spine and both legs. There were difficulty in passing urine at times and some after-dribbling. He passed urine five or six times during the day and lately had risen from three to seven times at night. He had been treated by a surgeon in a provincial town for sciatica. Dr. Atkinson suspected that the pain originated in prostatic disease. When I examined him in November, 1905, he complained of constant pain at the base of the sacrum and in each sacro-iliac synchondrosis and in the lower part of the sacrum and coccyx. The pain extended along the posterior aspect of each thigh to the

Up to the present the number of available measurements is too small to permit of a general classification on this basis. The legs of the negro are described as slender, with a poor development of calf muscle, but this is not always the case. The head is long, usually doliohocephalic, but is broader among the natives of the south and east than among those of the north and west. In the forest zone of central Africa, *from the great lakes to the west coast*, a short-headed element appears, probably from some strains of pygmy blood. A considerable degree of prognathism is common, being most marked among the peoples of the forest zone. It is more marked on the west coast than in the lake region or in South Africa. It also appears to be more prevalent in German East Africa than in the British territories to the north and south. The nose is very broad and flat, but in areas in the central Soudan, the great lakes district, and downwards through the central plateau to South-East Africa are tribes in which many individuals present a much higher and narrower nose with a better-formed bridge. Again, it may be noted that the tribes in German West Africa are more platyrhine. Scanty as is our present information as to this character it would appear to be the most available medium for classification on a physical basis.

A surprising degree of uniformity of features appears to exist throughout negro Africa. Sir H. H. Johnston declared that "if you took a negro from the Gold Coast of West Africa and passed him off amongst a number of Nyasa natives and if he were not remarkably distinguished from them by dress or tribal marks it would not be easy to pick him out." Again, "The average man or woman of Liberia might very well pass current as a native of Uganda, of the Swahili coast, Nyasaland, Ashanti, or Old Calabar." Other travellers bear similar testimony, which is amply confirmed by photographs from all quarters. We must therefore believe in a fundamental negro type spread evenly over the southern half of the African continent. Along the north of the negro zone in the Soudan, in the lakes district, and throughout central and south-eastern South Africa, are tribes with many individuals of a higher type, evidently the results of a racial cross. These types also present close resemblances to one another irrespectively of their geographical position, as may be illustrated by a comparison of the Mandingo, the Zanzibaris, and the Zulu-Kaffirs. Sporadically this type appears throughout Bantu-speaking Africa. Before considering the relations and origin of this higher type it is necessary to adopt some form of classification; the simplest and most usual rests on a linguistic basis. By this the negro peoples can be divided into two main divisions along a line passing from the Rio del Rey across the watershed between the Chad and the Congo basins at the 5° N. parallel, trending south-east through the forests of the Welle to the Semliki, touching the Victoria Nyanza save on its north-eastern coast, and passing due east from Kavirondo Bay to the sources of the Tana, thence along that river to the Indian Ocean. South of this line all the negro peoples speak languages bearing a very close resemblance to one another which are classed together under the designation Bantu. North of this line are spoken a large number of different languages which have been classified into some 19 main divisions. These may for convenience be termed Soudanese. This Soudanese section has been further divided by Keane and others into eastern, central, and western groups. The more important tribes in each group are—

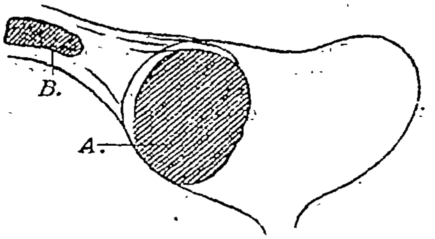
Eastern group.—The Barun and Boma on the north-western slopes and outliers of the Abyssinian plateau; the Berta, Dinka, Shilluk, and Bari of the upper Nile valley; and the Bongo, Zandeh, and Monbottu of the Bahr-el-Ghazal, and the appreciated by the unpractised finger. There is no mobility approaching that of the uterus or kidney, but the prostate has a mobility which becomes evident when a healthy organ is compared with a malignant one. Chronic inflammation which has spread from the prostate or vesicles to the pelvic areolar tissue may fix the prostate, but in doing so the tissues are matted and the outline of the prostate is obscured. There are a notable lack of hardness and a long inflammatory history that distinguish these cases. A few malignant prostates of the smooth, symmetrical, well-defined type retain their mobility.

FIG. 4.



Malignant disease of left lobe of prostate. A, Hard nodule. B, Enlarged lymph gland.

Before passing on to the spread of cancer of the prostate I shall make a note in regard to the diagnosis from prostatic calculus. The two conditions may present some similarity on rectal examination. The nodular form of malignant prostate gives the impression of a number of irregular calculi imbedded in the prostatic substance. But a number of large calculi, as these would be, are packed closely together into a single mass and usually lie in a single cavity so that the finger can detect a grating as they rub together. The rectal surface is smooth, not irregular, and there are no sharp points or hard ridges projecting through the rectal mucous membrane. Such a collection of stones almost always lies in a cavity communicating with the urethra and can be detected with the sound. The smooth well-defined type of malignant prostate may resemble a large single calculus. In the cases I have observed such a calculus always occupies a distended prostatic urethra and is readily distinguished by the sound. A single hard nodule in one lobe may be difficult to diagnose where the sound gives no information and the finger detects no grating. An enlarged lymph gland at the side of the prostate will point to malignant disease. Calculus is usually found in much younger men and the x rays will give valuable assistance in doubtful cases.

In the more advanced cases of cancer of the prostate two directions of spread can be detected by rectal examination. The growth may extend upwards along the base of the bladder. (Fig. 5.) Blocking of the seminal vesicles, to which I have already referred, may simulate this, but where the disease has actually spread in this direction the contour of the vesicles is obliterated and a hard mass passes up beyond this level. (Fig. 6.) One side has usually spread higher than the other. Hard stony ridges may be felt on the extension. High up the growth spreads outwards towards the side of the pelvis and it may sometimes be felt encircling the wall of the rectum. In the second direction of spread the growth extends laterally so that the sulcus on either side of the prostate is filled and the finger, instead of dipping into a groove and appreciating the antero-posterior depth of the prostate, passes over an even surface to the side of the pelvis and gains the impression that the prostate has diminished in size or has disappeared. The lymphatics of the prostate pass upwards and outwards on either side at the upper part of the organ immediately below and outside the seminal vesicles. Just beyond the prostate at this spot lies a small lymph gland which is frequently enlarged in malignant disease of the prostate and sometimes also in vesical carcinoma. It is the first link of a chain of lymphatic glands that pass out to the internal iliac group.

Treatment.—A large number of cases of cancer of the prostate have progressed too far when the diagnosis is made for any radical operation to be considered. Treatment will then consist in relieving symptoms. The occasional passage of a good-sized metal bougie may give much relief from the difficulty of micturition, but if hæmaturia is a feature of the case instruments should be avoided. Catheter life may become necessary from increasing obstruction, or a permanent suprapubic fistula may be demanded. For the pain nothing short of opium will suffice and there is no reason for withholding it. I have elsewhere[2] given an account of the operations that have been performed for malignant disease of the prostate and shall here confine my remarks to my own experience. The methods open to choice are the suprapubic and the perineal.

1. *Suprapubic enucleation.*—On opening the bladder in an early case of malignant disease of the prostate it is usually found that the organ does not project into the bladder or at most forms a projecting rim around the opening of the urethra. The mucous membrane is leathery and bound down, and tough bands pass outwards and backwards beneath the bladder wall. The internal meatus is rigid. The forefinger forced into it is tightly gripped. Attempts to commence enucleation by forcing the finger through the posterior wall of the prostatic urethra or through the mucous membrane on the vesical surface of the prostate are unavailing or only succeed after a struggle. The assistance of scissors or a knife may be required. The digital enucleation once commenced is continued with much difficulty and without any line of guidance until finally several masses of tissue of india-rubber-like consistence are torn out. There remains a space like an egg-cup, with walls of a tough leathery consistence, from which scraps of tissue can still be scraped. The bleeding from this cavity is remarkably slight. There are other cases where the enucleation commences without great difficulty but the gland is *firmly* adherent to the sheath and is incompletely separated from it after a struggle. In another type of case one lobe is easily shelled out and the second lobe is partly enucleated, leaving a thick shell of adherent tissue. I have operated on four cases of this type by the suprapubic route. One of these died from shock

---

[2] The Practitioner, February, 1908.

longer legs and may have served to spread the long-legged negro throughout the southern area.

The two features of the nasal index and the proportion of the limbs promise to yield much information for the classification of the negro peoples and it is to be hoped that ample data may be forthcoming from those anthropologists who are actually working in the field, but their numbers are few.

The materials for the study of the osteology of the negro peoples are somewhat more extensive, at least so far as skulls are concerned. Unfortunately, in the past a number of specimens have been sent to English and other museums without any exact information as to the tribe to which they belonged and have to be entered in the catalogues as negroes from unknown localities, which renders them practically useless for comparative study. Good collections of skulls are available from the Gold Coast, Ashanti, and Dahomey, representing the Western Soudanese, from French Congo, South Africa, Nyassaland, and the Kilimanjaro district; while there are a few from the upper Nile, Uganda, and the Congo basin. Material for the study of the rest of the skeleton is almost entirely lacking. By grouping together these skulls it was possible to obtain sufficient numbers to yield results. The grouping decided on was to place all the Ashanti and Dahoman skulls together, to make a group of Zulu-Kaffirs, another of the specimens from Nyasaland, these being subsequently found so similar that ultimately they were treated as one group of Eastern Bantu. The skulls from French Congo were grouped as Western Bantu and the Djagga collection at Berlin was treated separately. Owing to the almost complete absence of female specimens from some of the groups male skulls only have been used for comparative treatment. It at once appeared that there was a marked difference between these groups: the Western Bantu showed many more broad-headed skulls and much more prognathism than the Eastern group. The Ashanti were more prognathous and more dolichocephalic than the Eastern Bantu but slightly less prognathous than the Western. Both Ashanti and Western Bantu are very platyrhine, but the Djagga are particularly remarkable for the extensive prevalence of this feature. It may be noted that the few skulls from British East Africa and from the Congo side of Tanganyika do not show this to any greater extent than the Eastern Bantu. The skulls of the Eastern group are also in almost all dimensions larger than the rest. To the eye the resemblances rather than the differences between individual skulls certainly appear the more prominent, but when the average measurements and their standard deviations are considered the grounds for grouping are quite evident.

For each skull a selection of nine measurements, out of some 40 actually made, has been taken and the averages and standard deviations of each group have been calculated. The averages were then charted in pairs on squared paper, the one dimension being used as ordinates, the other as abscissæ. The pairs were so chosen that the two dimensions compared in the construction of the ordinary indices were recorded simultaneously. Thus in the figure showing the comparison of length and breadth of the skull the lengths were used as ordinates and the breadths as abscissæ. Thus the average length of the Eastern Bantu skull (average of 116) was 186·3 millimetres and the average breadth 135·4 millimetres, so that a point at the intersection of the corresponding lines on the diagram represents the average for both characters. It has been shown that the chances are approximately 1000 : 1 that the average of any subsequent group of the same size will fall within the limits of this average $\pm 3 \frac{\text{standard deviation}}{\sqrt{\text{number of observations}}}$. The standard deviation of the skull length was 6·8132 and the number of skulls 116. The value of $\frac{s}{\sqrt{n}}$ was therefore $\frac{6\cdot8132}{\sqrt{116}}$, i.e, 0·6592; three times this or 1·9 represents the amount to be added to, or subtracted from, the average in order to obtain such a range that the chances are 1000 : 1 that all subsequent averages of similar groups would fall within it. In this case the range is 186·3 ± 1·9, i.e., from 184·4 to 188·2. This range is then marked on the diagram. Similarly the range in breadth is $135\cdot4 \pm 3 \times \frac{5\cdot9152}{\sqrt{116}}$—i.e., ± 1·7 or 133·7 to 137·1. This also is charted on the diagram and the rectangle of which these values are the sides is constructed. Within the area thus included the chances are 1000 : 1 that the point representing the average of any subsequent group of the same kind would fall. When series of such rectangles constructed for different groups of skulls do not overlap the odds that the differences between the dimensions are not due to mere chance selection will exceed 1000 : 1. In the accompanying diagrams such rectangles are shown for the Western Soudanese negro, the Eastern and Western Bantu, the Bushmen and Hottentots, and for the Egyptians, the latter representing the only available measurements of skulls of a Hamitic race. These are from the measurements recorded in Arthur Thomson and Randall McIver's "Ancient Races of the Thebaid"; the others are entirely from my own measurements.

Six pairs of measurements are contrasted. The Bushmen, Hottentots, and Eastern Bantu may be noticed in each case to form an ascending series. The Hottentots are more nearly a mean between the Bushmen and Bantu than between the Bushmen and Egyptians, which supports the argument that whatever be the origin of the Hottentot race it has some negro blood. The Eastern Bantu are clearly marked off from the Ashanti (Western Soudanese) group. The Western Bantu are in many respects intermediate but are distinct from the Soudanese in a sufficient number of characters to show that a real difference exists. The Egyptian group may be noted to differ from the Ashanti in the same direction as the Eastern Bantu but in most cases to present smaller dimensions. It would therefore scarcely seem certain that the Eastern Bantu could be looked on as a cross between the negro and the Egyptian, but rather that some similar element to that found in Egypt might have entered into their constitution. Such an element is to be looked for in the Southern Hamites or Ethiopians represented by the Abyssinians or Somali.

The exhibition of photographs affords the simplest method of demonstrating the existence of race mixture. The line of contact between the negro and the white races took place mainly along the Nile valley, across the Sahara into the Central Soudan, the direct route up the Nile to the Great Lakes being closed by the marshes of the Sobat-Nile confluence. A further line was from the Abyssinian highlands to the lake country, and later a certain degree of penetration occurred from the coast. The white races affecting the Soudan were the Hamitic Egyptian and Berber peoples. A distinct gradation from white to negro can be traced: (1) from Morocco to the Gambia; (2) from Egypt through Kordofan to the Central Soudan and the Gold Coast; and (3) from Abyssinia and Somaliland, past the Great Lakes plateau into Southern Africa; but in this area the negro is of a higher type.

While this offers a reasonable explanation of the superior types of Bantu and Central Soudanese other differences between the northern and southern negro have to be explained. Several observers in British Central Africa, and particularly Sir H. H. Johnston, have noted that labourers belonging to the Bechuans and other Kaffir tribes coming to work in Nyasaland could be distinguished by a greater flatness of the face which could well be accounted for by a slight admixture of Bushman blood, and it seems that it is those tribes who have been longest in the south who present this feature to the greatest extent. The greater prognathism and the appearance of a broad-headed element in the Western Bantu receive an explanation from the presence therein of the prognathous pygmy. Also in a large part of French Congo and the Camerun the Bantu is a recent intruder pressing up in successive waves from the Congo basin into the coastal districts, each tribe forcing on its predecessor. The tribes near the coast probably contain much northern negro blood; the later comers are in large part of the superior type. Johnston describes them as tall, upright, with a fine face, high thin nose, beard, moustache, and a plentiful crop of hair; the others ill-shaped, loosely made, with splay feet, high calves, retreating chin, no hair on the face, and the wool on the head close and crisply curled. It is the presence of the superior type which marks off the Bantu from the Western negro. Probably the type in the Central Soudan is very similar, but of this there is as yet not sufficient evidence. As can be seen from a study of African history, it is this type that has made such progress as has occurred in negro Africa, the unmixed type really appearing to be retrograde in every tendency.

A REPORT ON 50 CASES OF ANALGESIA BY THE INTRASPINAL INJECTION OF STOVAINE.[1]

BY LAWRIE H. McGAVIN, F.R.C.S. ENG.,
SURGEON TO THE "DREADNOUGHT" HOSPITAL; LECTURER ON CLINICAL SURGERY AND TEACHER OF OPERATIVE SURGERY IN THE LONDON SCHOOL OF CLINICAL MEDICINE (POST-GRADUATE.)

OF the many novel methods of modern surgery of comparatively recent introduction perhaps few have been so startling and so full of promise as the induction of analgesia by the intraspinal injection of various drugs. Few methods have placed in our hands so powerful a means of combating the great danger of administering general anæsthetics in the presence of certain cardiac and pulmonary affections. And yet in spite of the fact that in this country the method has been placed on a sound footing by Mr. A. E. J. Barker, who has been the pioneer of this branch of surgical progress, and that this surgeon has, after an extended trial, urged its wider adoption in current medical literature, comparatively few surgeons have thought it worth serious consideration. Recently its claims were advocated by Mr. H. P. Dean, Mr. C. A. Leedham-Green, Mr. E. Canny Ryall, and others,[2] and considerable difference of opinion prevailed as to the drug most suitable for the purpose. It is not my intention to enter into a discussion of the merits of stovaine, novocaine, tropacocaine, or other drugs, such experience as I have obtained being solely of the first mentioned; for I feel that the experience of one surgeon utilising the same drug in a number of cases is of more value than if that surgeon had experimented with three different drugs in the same number of cases. The cases here presented are published solely in order that they may swell the number already reported in this country, by which means alone a satisfactory estimate may be arrived at of the comparative value, or the reverse, of the method in question, as opposed to that of general anæsthesia and more particularly as regards chloroform.

It is interesting to consider first of all the objections that are raised to intraspinal analgesia by those who have not seen the method applied, or who are for various reasons obstinately opposed to its introduction. In my personal experience the chief of these has been that the spinal cord is bound to suffer in some mysterious way, either at the time of injection or at some later date. What particular form of disaster is anticipated is not clear, but it appears to concern the chance of paralysis of some unexplained origin, the pathology of which is, I find, not usually forthcoming on investigation.

Again, there are those who, Cassandra-like, harp on the great danger of septic infection of the spinal canal, extension of the analgesia to the centres of respiration and circulation, the uselessness of the method above the umbilicus, and who appear to have a rooted objection to the patient retaining consciousness during the operation. It is but natural that the skilled anæsthetist should look with disfavour upon a method which *appears* to threaten to supersede to a great extent the time-honoured science of which he has been an able exponent; and as in conversation with many well-known anæsthetists I have heard these objections repeatedly urged and have been asked to believe that ether is the one great harbour of refuge from the risks of chloroform, that there is no real necessity for the introduction of intraspinal analgesia, and that the whole thing is simply a passing fad imported from abroad, I feel bound to say in the first place that I do not for a moment believe that general anæsthesia is threatened with extinction, nor would I for one wish that it were; secondly, cases do occur in which any form of general anæsthesia is out of the question; thirdly, a skilled anæsthetist is not always available; and lastly, I can see no valid reason why the induction of intraspinal analgesia should not be in the hands of the skilled anæsthetist, provided he is fully versed in its technique and in the necessity for aseptic methods. In support of this last statement one has only to remember that although the analgesia provided by stovaine is usually ideal and of considerable duration, cases are met with in which the analgesia is insufficient or its level not sufficiently high. In these circumstances one is compelled to have recourse to a general anæsthetic, and therefore I prefer to consider intraspinal analgesia as *an addition to* the armamentarium of the skilled anæsthetist rather than as an encroachment upon his department.

Recently, following the excellent work of Mr. Barker which much impressed me, I commenced to employ the method in my own wards at the "Dreadnought" Hospital, and this report concerns the first 50 of these cases, for assistance in taking the notes of which I am much indebted to the resident staff of the hospital as well as to several of the post-graduate students in the London School of Clinical Medicine, and to all of whom my thanks are due. I may say that the method of intraspinal analgesia was not indicated in all of these cases, and therefore was only applied to those patients who willingly agreed to its application or who requested it in preference to general anæsthesia. Of these latter there soon was quite a number, the method rapidly becoming popular among the patients, who recounted their experiences to others in the wards. The solution employed was that prepared by M. Billon of Paris after Mr. Barker's formula,[3] and the latter's methods were closely followed; the doses, however, especially in the later cases, were kept as nearly uniform as possible for purposes of comparison. As I have for the sake of brevity and ease of comparison tabulated the whole of my cases it would be waste of time to consider them individually, and I will therefore only refer to those in which there is some point of interest bearing especially on the question of this method of inducing analgesia.

CASE 1.—This case was one of a gigantic inguino-scrotal hernia in a plethoric man, 62 years of age. It was necessary to attempt the cure of it by the implantation of a filigree of silver wire by the double-section method recently described by me.[4] The patient was found to be suffering from double aortic disease and it was considered unsafe to give him any form of general anæsthetic. The hernia was so large[5] that I feared that in this, my first case of analgesia by this method, the effect of the stovaine might not be sufficiently prolonged to permit of so extensive an operation as was necessary being completed under its influence. This, however, had to be risked, and accordingly six centigrammes of stovaine-glucose solution were injected in the middle line between the second and third lumbar spines. Analgesia was complete in eight minutes, rose to the level of the nipples, and lasted 80 minutes. In spite of the extensive nature of the operation, the whole of the sigmoid colon being adherent to the sac and requiring to be freed by dissection from it, no difficulty was experienced and the parts remained perfectly insensitive at the close of the operation. Ligature of the omentum was felt slightly as a tactile sensation, not as pain.

This case is typical of the class in which the method is genuinely indicated and shows a duration of analgesia which would suffice for most surgical procedures.

CASE 2.—This case was admirably illustrative of the influence of spinal analgesia in combating shock. The patient was admitted terribly mauled by having been caught by a pulley making 1700 revolutions per minute. Both feet were reduced to pulp by compound fracture dislocation; the base of the skull was fractured; the skin of the left side of the chest was so scored that eventually a patch of the size of a breakfast-plate sloughed out; and the sacrum was so badly bruised that three large bed-sores soon appeared. The patient was thought to be dying, but four days later he rallied and it was determined to amputate the right leg which had become gangrenous. The site of injection was just above the bed-sores and had to be very carefully cleansed. Six centigrammes of the solution were used and in seven minutes the operation was commenced, the limb being removed at the tubercle of the tibia. No pain whatever was felt and in spite of the very serious condition of the patient there was no sign of shock and he ultimately recovered.

Five months later it became necessary to remove the other foot for intractable pain and deformity (Case 35) as the patient was quite unable to bear the weight of his body on the anterior part of the foot. He again chose stovaine in preference to general anæsthesia and under its influence a Syme's amputation was performed. The injection was made through the same space as before without difficulty, the flow of fluid being as free as on the first occasion. No ill effects followed and the patient expressed himself as much in favour of the method of analgesia as compared with general anæsthesia, of which he had had previous experience.

CASE 4.—This was a case of oblique fracture of the tibia with marked displacement of the fragments. After injection the bone proved to be completely insensitive to drilling and a three-inch screw was used. The patient, who was a German, was much interested and chatted actively during the operation, which lasted nearly an hour.

CASE 6.—This was the first failure of the series. The flow of cerebro-spinal fluid was clear but very slow; no difficulty was experienced in the injection, but possibly some of the stovaine may have escaped into the extradural space. The knee-jerks disappeared and the legs became partially anæsthetic; the analgesia was, however, quite incomplete at the end of 12 minutes, and the operation, a radical operation for inguinal hernia, had to be done under general anæsthesia. No after-effect was apparent as the result of the combination of the two methods.

[5] This measured 25 inches in circumference and 15 inches in length.

knee. There was pain in each groin and in the perineum. He had not lost weight. The prostate was stony hard, fixed, and irregular, and a mass of infiltration extended up the bladder base. (Fig. 5.) At several points the growth was commencing to break through the rectal wall. There were no enlarged lymph glands in the lower pelvis or groins. The after-history was interesting and instructive. He returned to the surgeon under whose care he had formerly been, the diagnosis of malignant disease of the prostate was set aside, and the patient was sent to Droitwich. Eventually "prostatic abscess" was diagnosed and a perineal incision was made through which the malignant growth soon fungated, and when I heard of the patient in May, 1907, he was rapidly sinking.

Hæmaturia.—A misleading feature in the symptomatology of prostatic carcinoma is the absence in a majority of cases of hæmaturia. Blood was observed in the urine in only five out of 40 cases (12·5 per cent.) and in only one case was hæmaturia the initial symptom. In four cases blood was noticed in small quantity on one or two occasions; in one case there was a gradual steady increase in the blood in the urine for 18 months. The blood was dark or bright and occurred in one case at the beginning of micturition and in another at the finish. The rarity of hæmaturia is capable of anatomical explanation. The new growth is usually of the hard scirrhus type, which is comparatively avascular and is not prone to ulcerate. And further, the direction of spread is seldom towards the interior of the bladder and the prostatic urethra is not directly involved.

Emaciation.—Emaciation occurred in 15 cases (37·5 per cent.) but in most it was slight. In four cases it was rapid and extreme but in two of these the emaciation was due to urinary septicæmia. This fallacy much reduces the value of emaciation as a sign of malignancy in diseases of the urinary tract. Loss of flesh is rapid and extreme in all urinary diseases when sepsis has spread to the kidneys and is combined with urinary obstruction or even where renal sepsis without obstruction exists. In prostatic disease both these factors are frequently combined.

Intestinal obstruction.—Extensive infiltration of the rectal wall caused obstruction of the bowel in two cases.

I shall very briefly compare these symptoms with those of the diseases most likely to be confused with cancer of the prostate. Simple enlargement of the prostate usually occurs at the same age as malignant disease but if the symptoms appear much before the age of 50 years the disease is more likely to be malignant than benign. The early symptoms of simple enlargement are more often those of irritation than of obstruction, frequent micturition rather than difficulty, although cases occur where the symptoms are largely or solely those of obstruction from the beginning. The frequent micturition of simple enlargement unless caused by cystitis usually assumes a special type. The patient rests during the first part of the night and rises at 2 or 3 o'clock in the morning and several times after this. Pain apart from micturition and independent of obstruction such as I have described in malignant disease is not observed in simple enlargement. Hæmaturia is a much more frequent symptom of simple than of malignant enlargement. Emaciation does not occur in simple enlargement but this sign is only of diagnostic value where the urine is aseptic. The symptoms caused by stricture of the urethra may closely resemble those of malignant disease of the prostate but the pain and emaciation are absent and the symptoms usually commence at a much earlier age. There are some cases of disease of the spinal cord that closely simulate the symptoms of stricture and malignant disease of the prostate. In these cases the bladder atony is a more prominent feature than the other symptoms of nervous disease. The diagnosis may only be made by proving the absence of urethral obstruction and of any change in the prostate and by careful examination of the nervous system.

Examination of the patient. 1. *Enlargement of lymph glands.*—The inguinal lymph glands are frequently the seat of secondary deposit and are enlarged, hard, and discrete. They are enlarged in 16 per cent. of cases. In a doubtful case I have removed an enlarged inguinal gland and found a deposit of carcinoma in it. The lymph glands ranged along the iliac vessels and even along the aorta may be felt enlarged in advanced cases.

2. *Rectal examination: (a) the prostate.*—The characters displayed by a malignant enlargement of the prostate are hardness, irregularity, and fixation. These require some discussion. The consistence of a healthy prostate is elastic. Where chronic prostatitis is present it is firm and tough. In tuberculous disease there are hard nodules. The gland is stony hard where a prostatic calculus or malignant growth exists. In cancer the first impression gained by the finger is nearly always that a stone is present. Whether there is a single large mass or a nodule or many nodules this stony hardness is almost constantly present. In many malignant prostates there are small points or ridges on the rectal surface which are as hard and sharp as the edge of a flint and which appear to project through the rectal mucous membrane. There are a few doubtful cases so far as hardness is concerned. A malignant prostate may be small and very tough, but some other sign may be present by which the suspicion of malignancy is confirmed.

Irregularity of contour is a characteristic feature of *cancer of the prostate. There are several types to which* it is convenient to refer at this point. 1. The most frequent and characteristic *form* is a moderate enlargement made up of numerous irregular hard nodules separated by clefts and fissures. (Fig. 1.) The outline of the prostate does not show much alteration. At a fairly early period in any form of malignant disease of the prostate the *seminal vesicles* may be felt as large thick-walled masses lying above the prostate. The ducts are blocked and the vesicles are in a state of dilatation and chronic inflammation. 2. In a second form the prostate retains its natural contour and surface. (Fig. 2.) It is moderately enlarged, bi-lobed, smooth on the rectal surface, and it may be moveable; it is stony hard. Eight of my cases were of this type and among them was the case of total extirpation that I shall describe later. 3. A form more difficult to diagnose is a small, broad, flat, hard fixed prostate the outline of which is difficult to define. (Fig. 3.) 4. There are a few cases where the change affects only one lobe which is enlarged and hard or which may contain a hard buried nodule, while the remaining lobe may be natural in size and consistence. (Fig. 4.) The last character of the malignant prostate is its fixation. Mobility in a healthy prostate is not readily

27	Strongly built seaman.	M.	25	Inguinal hernia.	Very free.	6	1 min.	1 "	2 "	3 "	3 "	6 "	55 "	Costal margin.

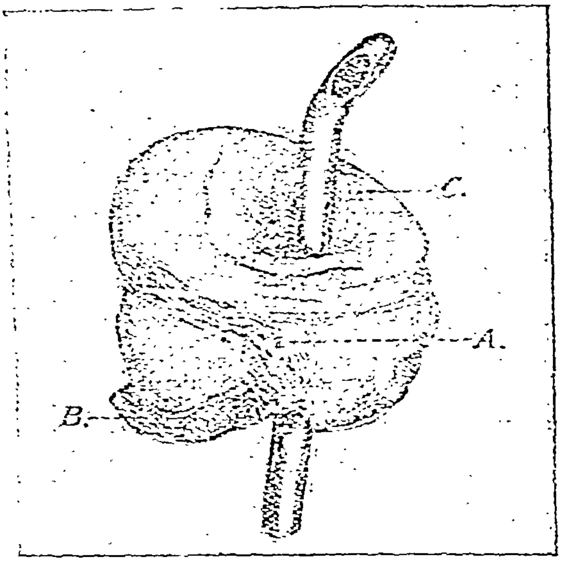
15 hours after the operation, another died two and a half months after the enucleation from septic pyelonephritis which had existed before the operation, another succumbed to bronchitis three months after the operation without having shown signs of recurrence of the growth, and the last case is well eight months after the operation but has had some hæmorrhage pointing to recurrence of disease. It cannot be said that suprapubic enucleation is satisfactory as an operation for these cases or that the after-results afford encouragement to continue this line of attack.

2. *Perineal operations.*—There are two methods by which a cancerous prostate may be removed by the perineal route: (*a*) Prostatectomy as it is performed for the removal of benign enlargement of the prostate. (*b*) A more complete removal of the prostate, prostatic urethra, sheath of pelvic fascia, portion of the bladder base overlying the prostate, and seminal vesicles.

(*a*) *Perineal prostatectomy.*—I shall not give the details of this operation for I have recently described it.[3] I have operated upon two cases of malignant disease of the prostate by this method. One patient is well two months after the operation and the other in good health after six months. This method of removal is the most satisfactory of those described, for the prostate can be very thoroughly dissected out and the posterior and lateral parts of the sheath removed. But a study of the anatomical relation of the prostate to the bladder base and prostatic urethra will show how intimate is the connexion between the muscle of the bladder base and the urethral wall with that of the stroma of the gland, and how ill-defined are the limits of the glandular tissue of the organ. And it will be seen that any method which stops short of removing the prostatic urethra and the muscular floor of the bladder which overlies the prostate will court recurrence of the growth. For this reason the more extensive operation elaborated by Young of Baltimore[4] is a sounder proceeding. But this operation is a very formidable undertaking, and on this account something short of an ideal method may be preferable in some cases.

(*b*) *Total extirpation of the prostate, prostatic urethra, seminal vesicle and bladder base (Young's operation).*—I have recently discussed this operation and shall therefore content myself with the relation of a case which will illustrate the method and the after-state. A man, aged 70 years, came under my observation at St. Peter's Hospital with symptoms of prostatic disease of three weeks' duration. The prostate (Fig. 2) was enlarged, smooth, bilobed, stony hard, and fixed. There was half an ounce of residual urine. The general condition was good. I operated on August 20th, 1907. With a staff in the urethra a curved, anteriorly convex, pre-rectal incision was made and the apex of the prostate was exposed. The membranous urethra was opened longitudinally and a Young's tractor was introduced. The posterior aspect of the prostate was exposed and an unusual amount of bleeding followed the separation of the rectum from the prostate. The lateral surfaces of the prostate were freed, the levatores ani muscles being somewhat difficult to control. The tractor was now depressed and the urethra cut across at the apex of the prostate, together with the veins passing to the prostatic plexus. The prostate was now drawn backwards and a retractor which had controlled the rectum was changed from the posterior part of the wound and placed under the arch of the pubis. The anterior surface of the prostatic sheath could now be seen and a head lamp was necessary for the further dissection. The space of Retzius was opened up and gave access to the front of the prostate and the pubo-prostatic ligaments could be seen high up. The latter were detached with the finger and the junction of the anterior wall of the bladder with the base of the anterior surface of the prostate could be seen and the vertical veins of the bladder wall identified. The limit of the prostate was defined with the finger and a transverse incision was made with a scalpel through the bladder wall just above this. When this opened the bladder cavity the fluid contents escaped. The incision was extended on either side by means of curved scissors and the bladder surface of the prostate could be turned down into the wound. An incision was now made transversely through the mucous membrane and muscle of the bladder base in front of the ureteric openings and this was deepened by blunt dissection to the upper surface of the seminal vesicles. The further steps of the operation consist in dissecting out the vesicles and vasa deferentia. I did not define the latter structure and, cutting too freely, incautiously cut across the vesicles and had to dissect portions of them away after removing the prostatic mass. (Fig. 7.) The large aperture in the bladder base, which would easily admit a Tangerine orange, was stitched antero-posteriorly from behind forwards until an opening which would admit the forefinger was left at its anterior angle. The whole bladder was now readily pulled downwards by the free ends of the knotted sutures. The cut end of the prostatic urethra was freed and united to the opening in the bladder by catgut sutures, with the help of a gum-elastic catheter passed along the urethra into the bladder. The ends of these sutures were left long and brought out of the wound. Some packing which had controlled the venous bleeding on either side of the pelvis was now removed, the levatores ani and perineal muscles were brought together with catgut stitches, and the wound was drained. The catheter was tied in place.

FIG. 7.



Specimen of malignant prostate after removal, viewed from the front, catheter lying in prostatic urethra. A, Prostatic plexus of veins. B, Portion of right levator ani muscle. C, Mucous membrane and muscle of bladder base.

The operation lasted one and a half hours and was well borne by the patient. The catheter was removed too soon by the house surgeon and the urine leaked by the perineum, and for a time it looked as if the whole wound would break down. The wound healed rapidly, however, and the patient left the hospital 29 days after the operation wearing a urinal.

It is now five months since the operation and the following is the patient's state (Jan. 29th, 1908). He is gaining weight and feels strong and well. Urine is passed four or five times during the day and three or four times at night. In the daytime when moving about he "weeps" a little, but the urine does not dribble away. He has discarded his urinal and finds that a cloth is sufficient to keep him dry. If he collects the escape in a urinal it amounts to half a wine-glassful for the whole day. At night he is completely continent and wears no protection. He wakes to pass urine three or four times, the warning sensation being a warmth and an aching in the perineum. There is no force in the stream and he must stand up to pass it. He passed one ounce of clear urine at my request and three ounces of urine were then withdrawn by catheter. Rectal examination showed a thick transverse ridge at the region of the bladder base due to scar tissue.

This is an operation for cases where the malignant disease has not spread beyond the limits of the prostate and it is the only one which holds out a strong probability of success. The operation depends upon early and accurate diagnosis and it rests with those who are in charge of such cases at the first onset of symptoms to see that a diagnosis is made.

50	Healthy seaman.	M.	—	Inguinal hernia. Implantation of filigree.	Free.	6	2 "	3 "	5 "	6 "	7 "	10 "	20 "	Iliac crest.
	Second injection given.				—	5	—	—	—	—	—	—	40 "	Ensiform cartilage.

CASE 15.—This was the second failure. It was a case of varicocele, and as in the former instance the flow of spinal fluid was very slow. The patient began to complain of pain as the veins were being divided, and although he said he could stand it and was unwilling to have an anæsthetic, he was obviously feeling it sharply and accordingly the operation was completed under ether.

CASE 18.—In this case the patient, a woman, 43 years of age, was the victim of a procidentia uteri of the most complete order and of bad chronic asthma. The operation (an original one and at present unpublished) involved the stripping of the peritoneal coat from the dorsal surface of the uterus. The analgesia lasted over three-quarters of an hour and was complete except that when the uterus was very forcibly dragged upon she complained of a pain in the chest (a symptom which I have noticed in one or two other cases when pulling on omentum or mesentery); she was, however, a very nervous patient and after the operation she said that she had really felt nothing of it. She felt no ill-effects whatever after the operation.

CASE 23.—Here the analgesia again failed completely. It was a case of inguinal hernia. Six centigrammes were injected, but the analgesia never rose higher than the scrotum and perineum and was not complete below that point. In this case, however, the flow of spinal fluid had been free. A general anæsthetic was given. There were no unpleasant after-effects.

CASE 26.—A woman was admitted for a recurrent attack of appendicitis. She was 36 years of age and healthy but extremely nervous, so much so that I hesitated to submit her to spinal injection; she, however, had a dread of chloroform or ether, and the operation was therefore done under stovaine. In 11 minutes the analgesia was complete to the ensiform cartilage, and with the exception that the patient complained of discomfort during the separating of some dense adhesions, which she referred to the epigastrium and for which a very few inhalations of chloroform were given, the method was perfectly satisfactory. She subsequently admitted that she had suffered no pain but had been a little nervous; she was never under the influence of the chloroform. Subsequently she was a little sick and her temperature was raised for two days.

CASE 29.—This patient was suffering from a very large popliteal aneurysm which threatened early rupture. He was also the victim of a commencing aneurysm in the arch of the aorta. The injection was made in the usual manner, six centigrammes being employed, the result being a complete and prolonged analgesia. The operation involved extensive dissection and handling of the popliteal nerves, but of this the patient felt nothing, tactile sensation even being in this case entirely abolished. It had been my intention to attempt to carry out Matas's operation of endo-aneurysmorrhaphy; the openings of the vessel into the sac proved, however, to be respectively on the anterior and on the posterior aspect, and therefore the old operation of Antyllus was done, about two pounds of clot being evacuated from the sac. The only after-effects consisted of slight headache, a temporary rise of temperature with a sensation of coldness but no rigors, and some aching of the back and loins, of which the patient made light. In spite of the severe handling of the popliteal nerves he made no complaint of subsequent pain, and is now perfectly sound.

CASE 33.—The patient was a man of 47 years of age, who was suffering from pulmonary tuberculosis with slight hæmoptysis and who had extensive caries of the tuber ischii with a large abscess in connexion with it in the right thigh. He was much wasted, and was not a suitable case for general anæsthesia. Six centigrammes of stovaine were used and produced a perfect analgesia to the level of the umbilicus. His condition on the table was excellent. The right tuber ischii was gouged away and the abscess laid open, scraped, and packed, the patient declaring himself perfectly comfortable. There were no subsequent complications in this case.

CASE 35.—In this case a man, aged 47 years, was admitted with acute retention of urine due to an impacted calculus in the urethra. He was in great pain and the stone was firmly gripped in the spongy portion of the urethra. Five centigrammes of stovaine gave complete analgesia to the umbilicus and the calculus was removed quite painlessly through a median perineal incision; it was of the size of a small cherry stone.

CASE 47.—I had occasion in this case to repeat the injection. The patient was a stout man, aged 42 years, with a very large vaginal hydrocele. The usual method was followed and six centigrammes of stovaine solution were injected, no difficulty being experienced in obtaining a good flow of cerebro-spinal fluid; in fact, the fluid came away almost as if under pressure. The fact that the knee-jerks were much exaggerated, as were also the plantar reflexes, and that he had a specific history may account for the complete absence of any result from the injection. After waiting nearly a quarter of an hour I injected a further dose of five centigrammes when gradually the analgesia established itself. It, however, only lasted a comparatively short time and was followed by no ill-effects.

CASE 50.—In this case also the injection was repeated owing to the short duration of the analgesia induced by the first puncture. The patient was a healthy man with a large inguinal hernia recurrent from an operation done abroad. The case was therefore treated by the implantation of a silver filigree. An injection of six centigrammes failed to give complete analgesia for longer than 20 minutes, although no difficulty had been found in making the injection; the patient was therefore turned over and a further dose of five centigrammes was given. Analgesia at once became complete and remained so for another 40 minutes. No ill-effects were noted and the patient declared himself well satisfied with the method.

I may say that the later cases in this series, with the exception of Case 49, have shown a distinct tendency to feeble analgesia, as have some of those recently treated and not included in this list. This may be due to the fact that M. Billon has ceased quite recently to manufacture the stovaine-glucose solution himself and has handed the work over to a firm; there may therefore be a difference in the strength of the new consignment from that originally prepared by M. Billon.

From a consideration of the cases detailed in this series I am tempted to record the impressions which I have gained independently of the method of intraspinal analgesia for the benefit of those who have not seen it put into practice; at the same time, it must be remembered that they are those of a beginner, and that although fewer failures may come with more experience the cases here reported are set forth as accurately as it has been possible to do, without any desire on my part to glorify the results obtained or to minimise the risks which time may possibly show the method to be attended by.

Remarks Bearing on the Performance of the Injection.

The difficulty of performing the injection has in none of the cases been serious; in one or two stout patients the second lumbar spine has not always been easy to define, but by arching the back to an extreme degree it can generally be recognised. In any case, if the injection happens to be made below or above this spine no great danger is likely to be run, but possibly the same cannot be said of injection at a higher level than the first lumbar spine. It will be noted that the second case of the series was injected in the first lumbar interspace in order to avoid the possible contamination of bed-sores. The direction of the needle I have found to vary much; as a rule it passes upwards and forwards, but in one or two cases injection has only been possible in a slightly downward direction. In nearly every case the cerebro-spinal fluid has been found at a depth of two to two and a quarter inches from the surface, this depth only being exceeded in very stout patients. If, therefore, a greater depth than this is reached in a thin subject when the needle is accurately inserted in the middle line and has not struck bone the failure to find fluid is probably due to a blunt point pushing the dura mater, which is comparatively tough, in front of it, or to the blocking of the cannula or needle with blood clot. In only one case did blood come freely from the needle after insertion. It did not vitiate the result of the injection nor was it followed by any ill effects.

The application of the ethyl chloride spray before the injection is made at once gets over the difficulty of the slight pain of the puncture, but this should not be carried too far for fear of hardening the skin to the extent of turning the point of the needle, in which case it may fail to enter the theca spinalis. In only one of the cases did the patient complain of the pain of the puncture. The spinal fluid not being easily found the needle was passed rather more deeply than usual when he suddenly complained of a sharp pain which he said shot from his back to his toes. This was probably due to one of the nerves of the cauda equina being touched. No ill result, however, followed.

The variation of the pressure of the cerebro-spinal fluid was throughout very noticeable. In some cases the fluid came from the needle as if under considerable pressure, while in a few cases, on the other hand, the flow was so slow as to result in a succession of drops. This was especially the condition present in two of the cases in which the analgesia failed.

I do not think that the sealing off of the puncture wound is a matter of great importance and it certainly involves some little delay in turning the patient upon his back and raising his head. There is not the least probability of infecting the spinal canal through this wound; if such a disaster should occur it must be solely due to the use of a dirty needle.

The prompt raising of the patient's head so that the foramen magnum shall be on a higher level than the dorsal curve of the spine is a matter to be very carefully supervised. This is, I think, shown by the fact that in Case 7, in which this duty was inadvertently carried out rather late, the analgesia rose to the level of the clavicles (the highest of the series), and the after-effects were seen in the occurrence of really bad headache, backache, and a tendency to rigors, although on the table the patient's condition was excellent. It is, I think, wise to keep the patient's head raised throughout the operation. Care should also be taken that the rest upon which the sacrum is raised in order to allow of the fluid injected gravitating towards the dorsal region of the spine is correctly placed and not allowed to slip, as it at times tends to do, towards the lumbar region; as in this case, a portion of the injected fluid may lie below the point of injection and only a small quantity reach a higher level. In perineal operations this is not a matter of great importance, the sacral nerves being those chiefly in question; but in operations on the groins, limbs, or abdomen it is fatal to the establishment of full analgesia. As soon as the analgesia is nearly complete this rest may be removed.

A little practice soon educates one's sense of touch to the extent of knowing the depth to which the needle has penetrated, the sensation of entering and leaving the ligamentum subflavum, of being in the extradural space, and of puncturing the dura mater being soon acquired and giving a great sense of confidence in one's manipulations.

Points of Interest regarding the Analgesia.

The most striking fact noticeable in this method is the tendency to variation exhibited in different cases as regards height, areas involved, duration and after-effects of the analgesia, even when the dosage remains constant, and the temperament and physique of the patients are comparable. As will be seen from a perusal of the accompanying table, the analgesia produced by a dose of six centigrammes of stovaine administered to patients of approximately the same class and age, varied in height from the knees to the clavicles; while in some cases no after-effects were noticeable, in others headache, nausea, backache, moderate pyrexia, and in one case slight rigors were met with. That these after-effects may be due to rapidity of absorption is possible; they probably have no connexion with the rapidity nor with the completeness of the analgesia, since these are the result of local contact with the sensory nerve roots and do not depend on absorption. Moreover, the severity of the after-effects does not always depend on the height of the analgesia, although in one case (Case 7) it would appear to have done so. In this case, in which the great height of the analgesia led one to be a little anxious as to its effect on the respiration and circulation, the patient's condition remained excellent on the table, his pulse and breathing appearing to be less affected than in several cases in which the analgesia stopped at a very much lower level. In spite of this variation it is possible to give approximately the order of events ensuing on injection, although the time at which these events occur varies in different cases.

The earliest and most constant phenomenon is the absolute abolition of all superficial and deep reflexes; usually within one minute the plantar, cremasteric, and patellar reflexes are all unobtainable. Following this the muscular sense gradually goes, the patient feeling his legs excessively heavy on an attempt to raise them, and in a few minutes, usually from two to three, the feet and legs are completely paralysed. It is noticeable here that the power to slightly flex and extend the toes remains. About the same time the perineum and scrotum become insensitive and these parts can usually be operated upon much earlier than the limbs and groins, the analgesia completely affecting the deep urethra and testis. The effect on the lower extremities is usually first seen on the peroneal aspect of the side upon which the patient was lying at the time of injection. By the time the lower part of the thighs has been reached the groins will usually be found quite insensitive and suitable for hernial and other operations, and by the time the upper part of the thighs has become analgesic the condition will generally have spread to the umbilical region, and in some cases even to the costal margin, the ensiform cartilage, or the nipples.

Not uncommonly tactile sensation remains to a blunted degree although sensation of pain is absolutely abolished; and in most cases there is an inability to distinguish the application to the skin of hot lotions from ether or ice, both conveying the sensation of tepid water.

The demarcation of the upper limit of the analgesia is usually very marked; half an inch higher or lower often leading from a normally sensitive area to one of analgesia. As regards the tissues themselves, all of them seem to become equally affected, with perhaps the exception to a slight extent of the peritoneum, omentum, and mesentery. Although these in most cases follow the rule of complete analgesia, cases occur now and then in which, although no actual pain results from their manipulation, ligation or dragging upon them appears to produce a sensation of dull aching in the chest and some nausea, which passes off, however, as soon as the manipulation ceases. Contrary to what one would expect to find, the two most sensitive tissues—the skin and the bone—appear to enjoy the most perfect analgesia, amputation and screwing being quite painlessly performed. Mr. Barker has drawn attention to the complete relaxation of muscles obtained by intraspinal analgesia and this has also been my experience. I have found it much easier to approximate the conjoined tendon to Poupart's ligament in closing the inguinal canal by Bassini's method under the influence of stovaine than by the aid even of chloroform.

The failure of analgesia which occasionally occurs is difficult of explanation except on three theories—viz., inefficient injection, only a portion of the dose reaching the spinal theca; natural insusceptibility of the patient; and inefficiency of the drug, due either to accidents during its preparation, its deterioration from keeping, or its contamination with other solutions in the operating theatre. I prefer to think that my failures are due to one of the two first-mentioned causes, first, because as I have already said I look upon my efforts rather as those of a beginner, and secondly, because the drug was freshly prepared to order. At the same time no difficulty was experienced in injecting these cases, and presumably insusceptibility to stovaine is as probable as to many other drugs. The possibility of one's syringe and needles being tainted with soda solution must be allowed, although in these cases the greatest care was taken to avoid any contamination of this sort. The effect of the drug on the circulation is seen in most cases in acceleration of the pulse, and in some few others in diminution of its force, while in the case of the respiration the rhythm is little altered, but there is generally a tendency to sighing from time to time shortly after injection; this does not apparently arise from any discomfort nor feeling of weakness.

The return of sensation to the parts rendered analgesic will usually be found to take place in the reverse order to that in which the analgesia was established, the abdomen first becoming sensitive, then the thighs, after which the legs and perineum, and lastly, the feet; the reflexes return last of all. The rapidity of this return varies considerably; in some cases it has been difficult to say exactly in what order the various parts regained sensation, the whole of the analgesia appearing to pass off simultaneously. Sensation, however, invariably returns before motion, and the return of the latter is often accompanied by a feeling of weight, dull aching, or tingling in the limbs like "needles and pins," or a feeling of stiffness, all of which pass off in the course of an hour or so. I have not seen any case in which the power of the bladder or rectum was affected.

Are the After effects Worse than those of General Anæsthesia?

It is a little difficult to draw comparisons between these when well marked and the after-effects of chloroform, ether, &c., since the chief effect of stovaine is seen in headache and backache, whereas that of general anæsthesia consists of vomiting. I think the majority of us would prefer the comparatively short-lived discomfort of the former to the physical suffering and unpleasantness of the latter, especially when unduly prolonged. The difficulty of combating the sickness of general anæsthesia is well known and at times nothing seems to affect it. On the other hand, the pain and headache of stovaine analgesia will be found to be readily controlled by aspirin in doses of from 10 to 15 grains. In most of my cases the after-effects have been so trivial as not to merit serious consideration. I think that the fact that in every case in which a patient has had experience of both methods opinion has been unqualifiedly in favour of spinal analgesia is sufficient evidence that the after-effects of stovaine are preferable to those of chloroform or ether. A further testimony is afforded by the fact already referred to that many of my patients requested spinal analgesia on the advice of those who had already had it, and that the only three patients requiring a second operation again chose the method in preference to general anæsthesia. If among the after-effects we have to include certain cases reported from the continent as having terminated fatally or in which there was more or less permanent paralysis, I am bound to say that I know of no case in which such an accident has occurred in *this* country or when carried out according to Mr. Barker's directions. I believe the cause, if these cases have been accurately reported, must be sought in the combination of other drugs, and especially of adrenalin with the stovaine. This drug, which has been used abroad, with the intention of prolonging the analgesia, is to my mind an extremely dangerous addition to the solution, since its action depends on the temporary avascularisation of the spinal cord. It is in the highest degree probable that the anæmia of the cord produced by the action of adrenalin, if unduly prolonged, is capable of bringing about the death of the cells of the anterior and posterior cornua with a resulting degeneration of the nerves in connexion with them. But this is a matter which might well occupy the attention of the physiologists.

s in which Analgesia was brought about by the Intraspinal Injection of Stovaine.

	Motion possible.	Condition during operation. (P. = pulse. R. = respiration.)	After-effects.	Shock.	Pyrexia. (T. = temperature.)	Remarks.	Opinion of the patient.
	No.	Comfortable. Smoked a pipe. P. 120; R. 20.	Slight headache and vomiting, relieved by aspirin.	None.	T. 100°.	*Hernia very large. Circumference, 25 inches. Length, 15 inches.* Sigmoid adherent in all its length to sac. Felt ligation of the omentum slightly.	Much less unpleasant than chloroform.
	,,	Slight nausea after 10 minutes, relieved by brandy. P. 110; R. 15.	Nausea, feeling of weight in limbs.	,,	T. 101·5°. (? Due to septic state.)	Injection made above second lumbar spine to avoid bedsores. Bone quite insensitive.	Much prefers it to ether.
	In toes.	Excellent. P. and R. normal.	None.	,,	T. 99·8°.	Marked unilateral sweating of head after injection. Dilatation of sphincter was not felt.	Very favourable.
	No.	Chatted actively and smoked. P. and R. normal.	,,	,,	T. 100·4°.	Bone completely insensitive.	Very decidedly favourable.
	,,	Comfortable. P. 100; R. 18.	Slight headache.	,,	No.	Spinal analgesia by own request.	Quite satisfied.
	Yes.	—	—	—	—	Operation done under general anæsthesia. No symptoms referable to combination of methods.	—
	No.	Slight nausea for five minutes; analgesia perfect.	Pain in both legs. Bad headache and backache; slight rigor.	None.	T. 101·2°.	Head was raised rather late after injection; aspirin relieved headache.	Did not like it. Refused to have other side done under any anæsthetic; never had chloroform.
	Slight.	P. 108 and feeble; R. 15. Brandy; comfortable; analgesia perfect.	None.	,,	T. 99·5°.	Analgesia by own request; tactile sensation in deep urethra; no pain.	Very decidedly favourable.
9	No.	Pulse feeble, 118; R. 20. Slight nausea.	Slight headache.	,,	T. 100°.	Analgesia perfect; tactile sensation in deep urethra.	Very decidedly favourable.
0	,,	Excellent. P. and R. normal.	None.	,,	T. 101°.	Analgesia perfect; by own request.	Felt no pain whatever.
1	,,	Excellent.	,,	,,	No.	*Complained of some discomfort in epigastrium during ligation of omentum.*	Much prefers this to chloroform which he has had before.
2	,,	Excellent. Smoked a cigar. P. and R. normal.	,,	,,	,,	Analgesia by own request.	Very favourable.
3	,,	Excellent.	Tingling in legs; slight headache.	,,	,,	Analgesia by own request. Tactile sensation on ligation of veins.	Quite satisfied with the result.
14	Slight.	Very comfortable; chatting all the time.	Sharp pain in wound and aching in limbs relieved by aspirin.	,,	T. 100·8°.	Analgesia by own request and perfect.	Has never had general anæsthetic, but thinks he would rather have stovaine.
15	Yes.	—	—	—	—	Patient said he could stand the pain, but he was obviously suffering. General anæsthesia was substituted.	—
16	No.	P. 108 at first; afterwards normal. No nausea.	Some pain in chest and limbs.	None.	No.	Analgesia perfect.	Very pleased he had the new method.
17	Slight.	Excellent.	Slight headache and nausea.	,,	,,	Analgesia perfect.	Very satisfied.
18	Yes.	P. 110; later 80. Some nausea; rather nervous; felt epigastric discomfort on packing abdomen.	None referable to stovaine.	,,	T. 100°.	Got frightened towards end of operation. Asked for chloroform and then refused it after a short administration.	Thinks she was more frightened than hurt and would not mind it again.
19	No.	Excellent.	Headache, relieved by aspirin.	,,	T. 100°.	Analgesia perfect.	Very favourable.
20	Slight.	Slight rigor; feeling cold. P. and R. normal.	Rather bad headache; aspirin.	,,	T. 101·2°.	,,	Doubtful; but he has never had general anæsthesia.
21	No.	Lost his nerve and asked for chloroform, but afterwards refused it; P. 112.	None.	,,	T. 101°.	Analgesia good.	Unpleasant, but did not feel any pain.
22	,,	Slight nausea after ten minutes; P. and R. normal.	Aching in legs and slight headache.	,,	No.	Analgesia by own request, and perfect.	Very favourable.
23	—	—	—	—	—	—	—
24	No.	Good; feeling of emptiness in stomach.	Sharp pain in limbs and headache, both relieved by aspirin.	None.	T. 100·5°.	Analgesia perfect although not very high.	Would rather have the headache than be unconscious.
25	Slight.	Excellent. P. and R. normal.	None.	,,	No.	Analgesia perfect.	Quite comfortable.
26	No.	Good, but rather frightened at first. P. 102; R. 20.	A little sick after operation; no headache.	,,	T. 101·2°.	Good analgesia till operation nearly completed. Felt pulling on bowel and at this point a little chloroform was given.	*Was more frightened than hurt;* it did not really hurt at all.
27	,,	P. fell to 48. Head lowered without my knowledge. (Possible cause of after-effects.) Comfortable.	Severe pain in back and knees; vomiting for two hours; bad headache; flatulence.	,,	T. 100·8°.	Analgesia perfect.	Never had general anæsthesia, so cannot tell.

is not exerted upon the spinal cord itself, but upon the posterior, and to some extent upon the anterior, nerve roots.

What the maximum dose may be has yet to be proved; as will be noted 11 centigrammes were given in Case 50 without any ill-effects; but there must be few cases in which six or eight centigrammes will not suffice for all ordinary surgical requirements.

In view of the recent high death-rate from chloroform in certain quarters, I cannot help thinking that if the method of intraspinal analgesia had been more extensively employed and some of these cases submitted to operation under its influence such mortality would have been avoided. Finally, I would urge upon all anæsthetists the desirability of learning and adopting the method, not only for the sake of their patients but for their own professional welfare.

Summary of Cases of Intraspinal Analgesia.

Number of cases submitted to injection	50
Oldest patient	62 years.
Youngest	24 ,,
Largest single dose	6 centigrammes.
,, double ,, ...	11* ,,
Smallest dose	4 ,,
Greatest height of analgesia	To the clavicles.
Shortest interval between injection and operation ...	4 minutes.
Longest duration of analgesia	90 ,,
Average duration	51 ,,
Shortest analgesia in any completed operation	30 ,,
Number of cases in which analgesia rose to, or above the umbilicus	38 = 76 per cent.
Highest temperature due to stovaine after operation	101·2° F.
Number of failures to obtain sufficient analgesia † ...	3 = 6 per cent.

* I.e., 6 + 5.

† It must be remembered here that these cases were not submitted to a second dose, which, as in Cases 47 and 50, would probably have produced the desired amount of analgesia.

Mansfield-street, W.

RENAL HÆMORRHAGE IN CHRONIC INTERSTITIAL NEPHRITIS.

BY J. T. MACNAB, M.A., M.B., B C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.

IN the early part of the last century cases in which hæmaturia appeared without any symptoms gave rise to considerable speculation. Little was known as to their explanation and they were spoken of as cases of "hæmaturia sine materia," "renal hæmophilia," or even "hæmaturia from a healthy kidney."[1] As time passed certain obvious changes were found associated with this condition and these were considered to explain all such cases. They were then supposed to be due to new growths, stone, or tubercle. It was not until the end of the century, when the cystoscope (a great aid to our powers of diagnosis) came into use and advancing surgical skill justified the exploration of many of these obscure cases, that the group of unexplained hæmaturias again became prominent. To this group belong many of the cases which I propose to consider. By the term "chronic interstitial nephritis" I wish to indicate the condition also known as granular kidney, chronic Bright's disease, or cirrhosis of the kidneys as distinguished from a purely local nephritis due to some definitely local cause, such as an obstruction to one ureter or an inflammation ascending from the lower urinary tract. In granular kidney there is a widespread deterioration of the arteries and arterioles; there is also an increase of the arterial tension; thus it is not surprising to find that spontaneous hæmorrhages occur in many parts of the body. Dr. Samuel West[2] quotes statistics showing that from 15 per cent. to 75 per cent. of cases of granular kidney die from cerebral hæmorrhage; epistaxis is very common and may be the first symptom of the disease; while retinal hæmorrhages are of great value in its diagnosis. Many of these hæmorrhages occur late when the blood tension is markedly raised and the vessel walls are much weakened; these, then, are due to mechanical causes; others, such as epistaxis and (as I hope to show) hæmaturia, may take place at a stage when such gross changes are not marked, and may perhaps be due to some toxic process causing a local infiltration. The hæmaturia of granular kidney has not attracted so much attention as the other forms of bleeding, but it is by no means rare.

Sir George Johnson[3] first drew attention to this condition and regarded it as occurring in an "advanced stage." He considered that the blood came from the bladder and the pelvis of the kidney, rather than from the kidney itself, because it was unusual to find blood-casts of the tubes. The amount of blood lost during any one attack is, as a rule, small; but traces of blood may be found in the urine over long periods. The subject is dismissed very shortly in text-books; thus Sir W. Roberts[4] speaks of the hæmorrhage as "generally insignificant," and Professor W. Osler[5] merely says "there may even be hæmaturia." In 1885 Dr. West[6] published three cases showing that the bleeding might be quite severe; he considered it to be "vesical in origin, as, in the absence of acute nephritis, the urine was rarely smoky or dark in colour." Two years later Mr. A. A. Bowlby[7] described cases of "Profuse Hæmaturia in connexion with Granular Kidney," in which it was proved post mortem that the blood had come from the kidneys. These cases, however, were complicated by urethral obstruction, in one by an enlarged prostate, and in the other by stricture of the urethra. The *profuse* bleeding was probably induced by instrumentation. In the first case the patient had retention of urine, which was relieved by catheterisation. Mr. E. Hurry Fenwick[8] states that the sudden removal of much residual urine from such a case, in which the ureters and renal pelves are dilated, often causes dangerous hæmorrhage; "the intertubular vessels, and those in the mucous membrane of the conducting channels, being suddenly robbed of a support to which they had been accustomed, rupture; and blood escapes freely into the bladder." Mr. Fenwick also gives evidence to show that in the second case the bleeding was very probably due to irritation of the stricture, causing a "reflex hyperæmia" of the kidneys. Such cases I do not propose to consider, as they appear to be of a different nature to those in which there are no back-pressure changes. In 1889[9] and 1893[10] Mr. Fenwick drew attention to the hæmaturia of chronic Bright's disease: he considered it to be by no means uncommon, and stated that about 12 per cent. of the obscure cases of hæmaturia sent to him for cystoscopy belonged to this group. In 1892 Mr. C. W. Mansell Moullin[11] recorded a case of severe renal colic, associated with hæmaturia, in which a diagnosis of renal calculus was made; on exploration no stone could be found and post mortem, ten days later, nothing was found save granular kidneys.

In 1900 Dr. West,[12] writing about hæmaturia in his work on Granular Kidney, stated that it had often led to mistakes in diagnosis and quoted several cases. He considers copious hæmorrhage rare, but has known mild bleeding to persist for long periods. About this time Dr. G. M. Edebohls[13] published several papers concerning the surgical treatment of chronic renal disease, especially by decapsulation of the kidneys, but he did not devote any attention to hæmaturia. Mr. Fenwick in 1904[14] again wrote of this symptom in granular kidney and regarded it as occurring early in the disease before the advent of noticeable cardio-vascular or retinal changes, the clue to the cause of the bleeding being given by the urine which is of low specific gravity and contains a faint trace of albumin with tube casts. In March of last year a paper on the Hæmaturia of Chronic Nephritis by Dr. Arthur L. Chute of Boston[15] appeared in the *American Journal of Urology* but most of his cases appear to belong to the infected and obstructed groups with which we are not concerned; he lays stress on the importance of separating cases of hæmaturia due to Bright's disease from those in

which Analgesia was brought about by the Intraspinal Injection of Stovaine—continued

	Motion possible.	Condition during operation. (P. = pulse. R. = respiration).	After-effects.	Shock.	Pyrexia. (T. = temperature).	Remarks.	Opinion of the patient.
	No.	Excellent. P. dropped to 54 but no nausea. R. 18.	Flatulence only.	None.	T. 100·2°.	Analgesia perfect.	Very favourable.
	„	Excellent. P. 96; R. 18 Talking all the time.	Slight headache and backache.	„	T. 100·5°.	Analgesia perfect, although popliteal nerves dissected out and held aside.	Very comfortable all the time.
	Slight.	Excellent for 40 minutes when patient complained of pain. Chloroform given to finish.	—	„	No.	This injection was undoubtedly successfully made as shown by height and completeness of analgesia.	Thinks he could have stood pain; felt nothing at all for first 40 minutes.
	No.	P. rose to 132 soon after injection. Later it fell to 120, and was normal at end. R. 18 to 21; felt cold.	Next morning flatulence, headache, and pain in the knees.	„	T. 99°.	Analgesia perfect.	Very favourable.
	„	Felt sick soon after injection. Slight tactile sensation retained.	Headache and flatulence; no pains.	„	T. 100°.	„ „	„ „
	„	Excellent. P. 126; R. 18.	None.	„	No.	„ „	Never felt anything at all and was quite comfortable.
	„	Slight nausea after ten minutes. Relieved by brandy. P. 100; R. 17.	„	„	„	Analgesia perfect. Large mass of omentum ligated and removed painlessly.	Perfectly comfortable after nausea passed off.
5	Slight.	Excellent. P. and R. normal.	Very slight headache. Some pain in stump.	„	T. 99·8°.	Second time he has had stovaine. Requested it again on this occasion. Injection made through old puncture mark.	Very comfortable; thinks he felt tingling in the back during sawing of tibia, but no pain at all.
6	No.	Excellent. P. and R. normal. Slight nausea for a short time.	None.	„	No.	Analgesia perfect. Both sides operated upon.	Felt no pain whatever.
7	Slight.	Excellent. T. and R. normal.	Slight backache.	„	T. 100°.	Analgesia perfect.	Felt neither pain nor discomfort.
8	No.	Excellent.	Rigor on returning to ward. Headache, backache, pain in limbs, all relieved by aspirin.	„	T. 100°.	Tactile sensation in deep urethra where calculus was impacted. No pain.	Very pleased; was in great pain, which left him almost as soon as he was pricked in the back.
39	Slight.	Excellent.	None.	„	No.	Analgesia perfect.	Never had chloroform, but this was quite painless.
40	„	Slight nausea. T. and P. normal.	Backache and slight headache.	„	„	„ „	Quite comfortable.
41	Yes.	Excellent.	Headache.	„	T. 99°.	„ „	Never felt anything.
42	No.	Nausea 10 minutes after injection.	None.	„	No.	Tactile sensation retained; fourth and fifth fingers felt numb.	Quite comfortable after nausea passed off.
43	„	Good. P. 101; R. 8–10.	„	„	„	Analgesia perfect. Complained of difficulty of speech during operation.	Felt nothing of the operation.
44	—	—	„	„	„	Given in this case to lessen the shock of possible colectomy. Condition, however, proved inoperable. Operation done under chloroform.	—
45	No.	Slight headache. P. 92; R. 12. Felt "pins and needles" in legs; otherwise good.	„	„	„	Felt nothing of chiselling and drilling of bones.	Much prefers it to ether.
46	„	Excellent. P. 76; R. 13.	Backache.	„	T. 100·2°.	Second occasion of spinal analgesia. At his own request.	Quite comfortable all the time.
47	—	—	—	—	—	—	—
	Slight.	Tactile sensation in legs. Excellent. P. and R. normal.	Backache slight.	None.	T. 100°.	Patient had very exaggerated reflexes and ankle clonus slightly. Cause of failure of first injection not apparent. Testis.	Felt no ill effects except backache.
	Yes.	Good, but nervous. P. 130–150; R. 20–22.	„	„	No.	Deep urethra quite insensitive in this case.	Did not feel anything.
	„	Excellent. P. 100; R. 20–24.	None.	„	„	As at end of an hour track of urethra had not been found, general anæsthesia was given and catheter passed from bladder.	Was quite comfortable in his wound but felt cramped in lithotomy position.
	No.	Excellent. P. and R. normal.	„	„	—	Analgesia provided by first injection only lasted 25 minutes. The second injection provided another 40 minutes, or 65 minutes in all.	Felt no pain at all.
	—	—	—	—	—		—

previously when the hæmaturia recommenced; he was, however, markedly anæmic. The urine had a specific gravity of 1010 and contained blood but no casts and no tubercle bacilli were seen. Radiographs were again negative. The cystoscope showed that the blood came from the left side.

On Oct. 5th the following operation was performed by Mr. Fenwick, the anæsthetic being ether. An incision was made in the left loin and the kidney exposed; its capsule was found to be thickened and the kidney substance was firmer than normal. The upper part of the ureter was exposed and seen to be healthy. An incision was now made into the lower pole of the kidney along its convex border; it extended well into the kidney substance but did not enter the pelvis. This incision was then sewn up with catgut; the wound was closed, except for a drainage-tube, which was removed five days later. The wound healed by the first intention and the patient was allowed to get up three weeks after the operation. The urine after the first 24 hours was free from blood and from albumin and remained free until Oct. 30th when the patient was discharged.

In this case the bleeding, though never very copious, continued over so long a period that a severe anæmia was produced, the kidney disease itself not being advanced enough to cause an extreme cachexia. Simple medical treatment did not arrest the hæmorrhage while an operation at once brought about an improvement. The case is interesting for another reason, as it shows that the hæmorrhage may be persistently unilateral, though due to a disease affecting both kidneys and associated with, if not partly caused by, general systemic changes.

Frequency.—It is not possible to get an accurate idea of the frequency of hæmaturia in granular kidney at present, for quite a number of cases are not recognised as such, and the details necessary for their recognition are not recorded. My 31 cases were selected from 2229 cases of granular kidney. This gives a frequency of 1 in 72, probably far too low.

Age-distribution.—It was at first thought that hæmaturia occurred late in granular kidney, but this is not supported by the cases collected for this paper. The youngest case was eight years old, the eldest 64 years; the average age was 26·2 years and 65 per cent. of the cases were under 30. In Dr. West's statistics[16] 79 per cent. of cases of granular kidney were over 40 years at death, so that hæmaturia appears to be one of the earlier symptoms.

Stage of the disease.—In 21 of the cases there were no increased arterial tension, no thickening of the walls of the blood-vessels, and no other sign of disease, except the state of the urine. In these patients, then, hæmaturia was the first indication of a chronic nephritis, and called attention to it at quite an early stage of the disease. This is of some interest, as the early diagnosis of granular kidney is extremely difficult. In 31 cases the fundi of the eyes were examined with the ophthalmoscope, and in only six were changes (such as retinitis and retinal hæmorrhages) found; the other 25 were pronounced to be normal.

Sex.—Judging from these cases sex appears to have no influence in the causation of hæmaturia, 29 being in males and 16 in females, numbers which agree very closely with Dr. West's statistics with regard to granular kidney; he gives a ratio of 26 to 16.

Differential diagnosis.—Renal hæmorrhage is usually recognised by the fact that the blood is intimately mixed with the urine. I do not propose to discuss the diagnosis of the source of the hæmorrhage; in doubtful cases cystoscopic examination is most useful. A mild attack of hæmaturia, due to granular kidney, may be mistaken for a *subacute nephritis*. The chief differences are—(1) that there is little or no œdema; (2) the amount of blood and albumin in the urine fluctuates from day to day; and (3) the course of the case is different, as it may be weeks or months before the hæmorrhage ceases; when it does the urine is of low specific gravity and contains casts with a trace of albumin. As an example I quote the following case.

CASE 3.—A youth, aged 17 years, was admitted to the London Hospital under the care of Dr. F. J. Smith on Feb. 26th, 1906, with the following history. He had been ill for one month, complaining of a sore throat and "pains all over." During the second week he noticed some slight swelling of his face. He suffered from headache and was sick once. There had been nothing abnormal about the urine. He had never had scarlet fever or any other illness. On admission there was slight puffiness of the face and eyelids but no œdema of the legs or genitals. There was no sign of cardiac hypertrophy; the pulse tension was moderate, the artery wall was not thickened, and the fundi were clear. The urine was acid, smoky in appearance, of specific gravity 1024; it contained a trace of albumin. Microscopical examination showed blood-cells but no casts. The hæmaturia gradually diminished. On March 6th the urine was free from blood, and casts, both hyaline and granular, were seen. The amount of urine passed in 24 hours was from 70 to 80 ounces. Later, blood again appeared in varying amounts and on March 23rd the patient went home feeling quite well but still passing a small amount of blood in his urine.

This case was regarded as a subacute nephritis, but I submit that it was probably an example of hæmaturia due to granular kidney.

Hæmaturia due to *renal tuberculosis* will be recognised by the more marked nocturnal frequency. The cystoscope will also show changes in the ureteric orifices; above all, tubercle bacilli may be found in the urine.

Renal calculi may be detected by the aid of the x rays. There will usually be a *history of typical renal colic*, except *in the rare cases of aseptic embedded calculi which are most* difficult to recognise. Renal colic may, however, be produced by the passage of blood clots along the ureter, in which case these *are found* in the urine and can be recognised by their characteristic shape.

Malignant disease of the kidney in the later stages may be suspected on the discovery of a renal tumour on one side. The examination of the urine may show the presence of fragments of growth. In these cases there is usually profuse bleeding in the early stages sufficient to justify exploration of the kidney through the loin. When there are renal tumours with irregular surfaces in both loins it is probable that the hæmorrhage is coming from congenital cystic kidneys. I have recently seen such a case in hospital but at present the diagnosis is unconfirmed.

Hæmaturia due to the *bilharzia hæmatobia* is differentiated by finding the characteristic ova in the urine; in these cases the hæmorrhage is usually vesical. Mr. Fenwick[17] quotes a case of hæmaturia due to *tertiary syphilis* of the kidney. This was diagnosed by finding other signs of syphilis and by the effect of specific treatment. Mr. Fenwick[18] has also described cases of hæmaturia due to *angiomata* of the renal papillæ. In these the urine was normal and the diagnosis was only made in the course of operations rendered necessary by the profuseness of the bleeding.

Cause.—The hæmaturia of granular kidney does not appear to depend on the purely mechanical causes (high arterial tension and deterioration of the vessel walls) which bring about the later manifestations, such as cerebral or retinal hæmorrhage; for, like epistaxis, it may occur before these changes are noticeable. It is more probably due to local infiltration set up by some toxin; perhaps the same poison is responsible for the general vascular weakening which appears later, such changes appearing in the kidney first and advancing more rapidly there than in other organs.

Prognosis.—This depends almost entirely on the degree of kidney change that is present. Of the 45 cases which I collected only four patients died while under observation, and none of these from hæmorrhage, which shows that the bleeding is rarely severe or uncontrollable. Dr. West has followed a case for 11 years, and one patient treated at the London Hospital had been passing blood in his urine at intervals for 17 years. Anæmia was a marked feature in some of the patients, and this was doubtless partly due to the hæmaturia; but the bleeding is, as a rule, controlled by treatment and can hardly affect the prognosis much.

Treatment.—Rest in bed, purgatives, and a diet consisting chiefly of milk, eggs, and bread-and-butter will, as a rule, be sufficient to stop the bleeding. Hæmostatic drugs, such as calcium lactate or calcium chloride, may be tried, but are hardly necessary. Iron in some form will be useful during convalescence. 38 of the cases which I collected were so treated, and with the exception of three deaths all recovered. The three deaths were in advanced cases, all of the patients having retinal changes and other signs of marked cardio-vascular degeneration. Recurrence is extremely probable, for the cause, the chronic nephritis, still remains. One case was explored for a renal calculus which did not exist, and died ten days later. Surgical treatment has been tried in a

A Consideration of the Chief Advantages of the Method.

The complete abolition of the phenomena of shock is undoubtedly one of the greatest triumphs of spinal analgesia and has already been referred to in Case 2 of my series. For an explanation of this great result I would refer the student to Cushing's work on the cocainisation of nerve trunks.[6] This surgeon found that the preliminary injection of the great nerve trunks of the body before any operation upon the area governed by them completely abolished the phenomena in question. Intraspinal analgesia is simply another method of applying the operation advocated by Cushing, the sensory impressions resulting in shock being blocked at the posterior nerve roots instead of in the course of the nerve trunks.

The second great result of this method is that it has placed in our hands the means of bringing to operation in comparative safety many cases in which general anæsthesia would have been attended by very considerable danger from such complications as fatty and fibroid degeneration of the heart, double aortic and mitral disease, aneurysm, goitre, chronic bronchitis, and extreme nervous dread of anæsthesia.

The above are not, however, the only merits which the method can claim. The saving of time due to the rapidity of the analgesia, and the possibility of commencing in safety the antiseptic cleansing of the seat of operation during the progress of the analgesia, as well as the fact that no risk is run by radically altering the position of the patient on the table during the operation—such, for example, as rolling him over on to his face—are points of great importance. The necessity for preliminary and post-operative starvation, and the loss of appetite consequent on sickness and the unpleasant taste of ether in the mouth are entirely avoided by the use of spinal analgesia, and the patient can be fed, and brandy, &c., administered even in the course of operation, often a matter of great assistance in old and feeble patients.

The idea that there is a great disadvantage in the fact that the patient retains consciousness throughout the operation and is aware of all that is said and done is to my mind an erroneous one. I think that every surgeon of experience will admit that occasions arise from time to time, especially in abdominal gynæcology, in which it is advisable to obtain from the patient during the operation consent to some change in the method of procedure, the possible necessity for which has not been considered before the anæsthetic was administered. In the case of general anæsthesia either the surgeon must bear the responsibility for that procedure, or the patient must be sent back with the operation incomplete, to await a second operation when his or her consent shall have been obtained. Several such cases occur to my mind both in my own practice and in that of other surgeons, but considerations of space prohibit their quotation here. It is often of the greatest value to be able to question a patient during operation, and spinal analgesia permits of this. Should it be desirable to prevent the patient hearing the clatter of instruments, the sawing of bone, or the remarks of the operator or his assistants, the matter is easily accomplished by the use of plugs of wet cotton-wool or soft paraffin wax. As to the witnessing of unpleasant sights, nothing is simpler than a well-arranged screen across the patient's chest or a handkerchief tied across the eyes, at least one of which methods, preferably the former, is, of course, the usual practice.

Again, the advantage that the patient can at once be seen by his friends after the operation and engage in intelligent conversation with them is obvious.

Lastly, from the surgeon's point of view, the great danger is entirely obviated of strain being put upon abdominal sutures by retching, or upon the sutures of a Bassini's operation for hernia by the unconscious and often forcible extension of the hip-joint and other uncontrollable movements; and in the latter case certainly one of the chief predisposing causes of early recurrence is removed by the employment of spinal analgesia.

Cases in which the Sphere of Utility of the Method is Limited.

It must not, however, be supposed from what I have said that the method is in all points ideal; it certainly has its limitations, and I have already drawn attention to its tendency to variation and its occasional unreliability. Although I hold women to be commonly more courageous than men in the face of surgical procedures, it will at times be found that in extremely nervous women it is difficult to be certain when analgesia is really complete, so unwilling are they to acknowledge a condition which they fear may be only skin deep and may possibly pass off suddenly and leave them in great pain. Occasionally towards the end of their trial their courage may fail them and a general anæsthetic may be requested where none is really necessary.

The greatest disadvantage to my mind of spinal analgesia is met with when dealing with perineal conditions in women. Although the method is almost ideal for operations in this region in particular, the assumption of the lithotomy position is naturally an almost insuperable bar to its employment in private and (though to a less degree) in hospital practice. Even the lateral position would, I fancy, be little less offensive to the majority of women. In these cases there is no doubt that general anæsthesia is a *sine quâ non* from the patient's point of view, whatever the surgeon may think.

I have been asked frequently if a second injection is permissible in the event of failure of the analgesia, or where it does not last sufficiently long. Personally I have only recently attempted it and, as shown in Cases 47 and 50, the result was perfectly satisfactory and was followed by no ill-effects. There may, however, have been some doubt as to the stovaine having reached the spinal canal in the first of these cases, although I do not think so; there certainly was no doubt about the second. I can see no valid reason why it should not be done if the dose be carefully moderated; there is, however, an obvious objection from the point of view of asepsis as regards the operation, since it entails the rolling over of the patient and the displacement of all towels, &c., in order to carry out the injection.

Although the analgesia may in some cases rise as high as the umbilicus, in the present state of our knowledge the method must be regarded as unsuited to operations at a higher level than this and in many cases even at this point, for although such operations as those for umbilical herniæ of moderate dimensions might be commenced under its influence, it must be remembered that this region is the first to which sensation returns and therefore the duration of the analgesia cannot be so long as in parts at a lower level. For extensive operations here, involving the implantation of large filigrees of silver wire, it is at present quite unsuitable.

In the presence of bed-sores or ulcers occupying the neighbourhood of the second lumbar interspace the injection might be impossible and certainly is unsafe.

It remains to be proved that it is unsafe to insert the needle at a higher level than this space, and in cases in which the indication for spinal analgesia is imperative I should not hesitate to attempt it; but no doubt should exist in the mind of the surgeon as to the extreme care with which this step should be carried out, for although the cord itself runs no danger from the needle at the level of the second or third lumbar interspace the same cannot be said of injections at a higher level.

As far as I know, the method has not been put to serious test in children and the cases in which it might be called for in them must be very few. Recently I applied the method with perfect success in the cases of two boys, aged 14 and 16 years respectively, using a single dose of four centigrammes in each case.

Conclusions.

From a study of my cases and of those of other surgeons I am convinced that in spinal analgesia a method of the greatest value has been devised; I believe that in careful hands and with the particular stovaine solution employed by Mr. Barker it is a perfectly safe proceeding. The opinion of patients as to its merits is universally favourable and the after-effects of the drug are really trivial in the majority of cases, while in the remainder they bear comparison very favourably with those of the various general anæsthetics. The analgesia provided is, as a rule, of the most perfect order, available to all operations within the area involved. The excessive rapidity of the pulse noticed in some of the cases subsequently to injection has probably nothing to do with the drug itself; it is amply accounted for by the excitement of the patient, and it will be seen that it rapidly subsides on the discovery that the operation is really painless.

With regard to the frequent occurrence of tympanites, it is clearly explicable on the supposition that the rami communicantes of the sympathetic system of nerves are equally affected by the injection, the bowels becoming for the time being partially paralysed.

There can, I think, be no doubt that the effect of the drug capsule which surrounds a quiescent tuberculous focus is the herald of disaster, and it has indeed occurred that the use of thiosinamine in subjects of healed syphilitic disease of the throat with resulting fibrous overgrowth has caused so much softening and swelling of this tissue as to obstruct breathing and necessitate tracheotomy.[3]

---

[6] Annals of Surgery, 1902.

Another form of fibrosis should be noted here. It is that variety which apparently is not the result of inflammation but rather the sequel of degeneration. Thus it is met with in diseases of the spinal cord as sclerosis and as fibroid patches in the heart due to arterio-sclerosis of branches of the coronary artery. Thiosinamine is not reputed to exert any specific action on this form of fibrosis, though it has been used in posterior sclerosis of the cord (tabes dorsalis) with some improvement.[4]

Although the possibilities of thiosinamine as a drug of extraordinary value seemed very vast, an impediment to its general employment was offered by the circumstance that it is insoluble in water and its alcoholic solution caused severe pain on hypodermic injection. It was not until Mendel of Essen conceived the idea of combining it with sodium salicylate to form the soluble compound known as fibrolysin that this drawback was removed, and a pharmaceutical product was put at the disposal of the profession in a manner ideally adapted for use. Exposure to air or light causes decomposition of fibrolysin; it is therefore put up in sterile solution in hermetically sealed brown glass ampullæ, the contents of which measure 2·3 cubic centimetres, representing one-third of a gramme of thiosinamine. Each ampulla suffices for one injection. It should be stated that fibrolysin was prepared on the analogy of diuretin which is a combination of insoluble theobromine with sodium salicylate.

I may now indicate in a general way the clinical applications of fibrolysin. Unna demonstrated its benefits in cheloid, and his observations have been abundantly corroborated by others. A far different use has been found for the drug in treating urethral stricture; some writers record successes. Its effect has been put to the test in cases of adhesions between internal organs and even adhesions between serous surfaces. One of the recent reports concerns a case of delayed pneumonic resolution, where the consolidation lasted 10 weeks, but cleared up after injections of fibrolysin. Attempts have been made to obtain some advantage from it in relieving the fibrosis which causes valvular disease of the heart. Fibrous stricture of the pylorus and fibrous contraction of the palmar fascia (Dupuytren's) have in many instances yielded to a series of injections. In the special branches of surgery aurists have sought to alleviate deafness due to sclerotic changes in the labyrinth or adhesions between the ossicles. Ophthalmologists have resorted to it to disperse corneal opacities and to dissolve iritic adhesions.

A critical consideration of the literature impresses one with the view that fibrolysin does indeed possess legitimate applications to this wide field of therapeutics. This impression is emphasised by the personal experience of the writer, which, however, is limited to three cases. One was an instance of Dupuytren's contraction which underwent complete cure; another was a thick keloidal growth situated on the shoulder which improved marvellously; and the third was a case of hypertrophic thickening and lobulation of the skin of the nose (rhinophyma) which diminished sensibly in size as a result of fibrolysin injections. The injections, which must, of course, be given with full antiseptic precautions, are best administered deeply into the gluteal muscles. The proceeding is practically painless and it leaves no after-effects. There seems to be no advantage in injecting in the locality of the scar tissue which it is desired to influence. Fibrolysin has been given by intravenous injection when a rapid effect has been required. An odour of garlic and mustard emanates from the breath in a few minutes, showing that thiosinamine is speedily set free in the blood.

Promise of successful treatment is indicated by definite naked-eye changes, best seen, of course, in thickened pink scars and in typical cheloids which stand out in relief from the skin. These become paler, softer, boggy, and translucent, and their texture gets plastic and pliable. If the injections are abandoned at this stage there is a rapid reversion to the previous condition, because this change only implies a transudation of lymph into the scar tissue, an effect which can also be obtained by injecting hemi-albumose, peptone, urea, or uric acid. This change is, however, preparatory to the ultimate absorption of the morbid fibrous tissue. The microscope demonstrates that the new blood-vessels lose their definition of outline, their contour becomes confused, the angular processes of the fibrous tissue cells become separated from one another, and the component strands look swollen. The serous transudation may well be compared to Bier's treatment by inducing artificial hyperæmia. This treatment also softens indurations, loosens adhesions, and promotes the absorption of inflammatory products. It is perhaps necessary to add that normal fibrous tissue does not undergo these changes as the result of injections of fibrolysin.

When massage or other forms of physical treatment are likely to be serviceable in the relief of conditions for which fibrolysin is to be administered these measures should be simultaneously employed. The value of this is best illustrated by cases of stricture of the urethra and simple stricture of the œsophagus which have proved refractory to dilatation by bougies or sounds. The action of fibrolysin in softening the cicatricial tissue has in many instances permitted the passage of instruments through obstructions which were previously quite impassable, and in this manner has paved the way for effectual cure by mechanical dilatation. Some very striking successes have been achieved in stricture of the œsophagus by this method. The same principle applies to the treatment of joint adhesions in chronic arthritis. Rigidity, stiffening, and thickening are influenced by the fibrolysin injections, but these must be supplemented by massage, active and passive movements, and hydrotherapy. It has indeed been objected that the improvement following the use of fibrolysin is due to the physical therapeutics accompanying it. It has been pointed out that contractures of various kinds may eventually yield to mechanical measures. This, however, cannot apply to such conditions as stricture of the œsophagus, where such measures are impossible, and there are too many of these cases on record to justify the suggestion of mistaken diagnosis as put forward by a recent writer.[5]

It may well be admitted that clinical experience is as yet insufficient to support some of the claims for the therapeutic efficiency of fibrolysin. It exerts an influence on the scars of burns, but it is premature to apply it for the scar which causes traumatic epilepsy. On the other hand, benefit has followed its employment in the cases of perineuritis causing sciatica and other forms of neuralgia. But in regard to cases of pleural adhesions, pelvic cellulitis and its sequelæ, and other diseases where it is used on hypothetical principles, no definite opinion can be advanced. A case has been recorded where widespread abdominal adhesions following an injury and causing intestinal obstruction was cured by injections of fibrolysin.[6] More recently three cases of gastric adhesions have been published which have been so far cured by fibrolysin as to abolish the intense pain from which the patients suffered.[7] These results are fully explained on the ascertained pharmacological action of the drug.

Perhaps the most interesting of what may be termed the remote application of fibrolysin concern its use in middle ear disease. Some observations on its action have been made in the ear department of the General Hospital in Vienna.[8] The injections were given in the arm, beginning with a dose of 0·3 cubic centimetre, gradually increasing to the whole contents of one ampulla—i.e., 2·3 cubic centimetres. The treatment usually comprised from 20 to 30 injections spread over a period of about two months. The injections were discontinued when it was evident that they were not producing continued improvement in the hearing. The treatment was abandoned if no benefit was derived from the first eight or ten injections. The injections were not employed to the exclusion of other means of aural therapeutics, such as politzerisation, aural massage and electricity, but the cases were such as had not been in any way improved by these methods. They were examples of dry otitis media, adhesions to the membrane, and beginning sclerosis between the ossicles. It is obvious that when the sclerosis has advanced to ossification fibrolysin has no pharmacological application. The conclusions arrived at show that which nephrectomy is required but is inclined to advise surgical treatment, such as decapsulation, for these also.

[8] Monatsschrift fur Ohrenheilkunde, 1907, No. 2.

On looking through the London Hospital records for the last 15 years I have been able to collect 31 cases of hæmaturia occurring in what was regarded as chronic interstitial nephritis; in none of these cases could any other cause for the hæmorrhage be found, the urine was always of a low specific gravity—that is to say, about 1010—and contained granular or hyaline casts, or both; in some there were many other signs of granular kidney, in others these appeared later, while in many no further signs of disease could be discovered. To these I have added 14 cases collected from the literature. On examining the hospital notes I find that in the last year or two the heading "hæmaturia, ? cause" has been less often used and granular kidney is more often put down as the cause, this form of hæmaturia having received very little attention until lately. Some cases I selected had been recorded as ? acute or subacute nephritis, occurring in the course of granular kidney, and my reasons for including these are given lower down. On the surgical side I found six cases, all of which have been in the hospital within the last five years, none being recorded in any of the ten preceding ones, a fact which shows how recently these cases have come under the notice of the surgeon. In the course of my search I noticed a considerable number of cases of slight hæmaturia occurring in young persons, mostly under 21 years of age, who, after being elaborately overhauled as hospital in-patients, were yet discharged as "hæmaturia ? cause." A few of them returned later, to enter my group of chronic interstitial nephritis, but many have not been heard of again; I cannot help thinking that at least a portion of these were really cases of early granular kidney although on their discharge from hospital their urine appeared quite normal. The following case, in which the diagnosis was very doubtful at first, I quote at length, as the notes are now complete:—

CASE 1.—A schoolboy, aged 11 years, was admitted to hospital, under the care of Dr. G. Schorstein, on August 29th, 1903, as a case of "acute nephritis." On the 28th he awoke feeling sick and on passing his urine he noticed it was "red, almost like blood." He stayed at home that day, ate his breakfast and dinner, and in the afternoon vomited, but only a little; he slept well that night. Next day the urine was still red; he then came to hospital and was admitted. He had noticed no frequency of micturition, no headache or other pain, and no swelling anywhere. He had had a similar attack two years ago (no pain, no œdema, and no vomiting), and was in Bromley Sick Asylum for three weeks; he had been quite well since. There was no history of scarlet fever, measles, or diphtheria. There was nothing of importance in the family history. His condition on admission is described as follows: "A healthy looking boy, not anæmic, no puffiness of face, no œdema anywhere. Temperature normal. Pulse—no increased tension, vessel wall not thick. No sign of cardiac enlargement. Retinæ healthy. Lungs, nothing abnormal. Abdomen, no lump felt. Testes healthy. Urine, smoky, reaction acid, specific gravity 1016, it contains about one-tenth of albumin by volume (heat test). Microscopical examination shows the presence of blood cells and a few granular casts." The treatment was rest in bed, a milk diet, and purgatives as required.

Further notes are as follows. On Sept. 2nd no tubercle bacilli could be found in the urine. On the 29th the patient was allowed to sit in a chair for two hours daily; he felt and looked well, but was still passing blood in his urine as before. On Oct. 5th the patient had been complaining of aching pains in the lumbar regions and was not to get up again for the present. He was taking eight minims of tincture of perchloride of iron three times daily. From Oct. 16th until the end of November he had dry cupping to his loins daily; this at once relieved the pain and the hæmaturia diminished. On Nov. 3rd the urine was again found to be free from tubercle bacilli and radiographs of the kidney and bladder regions appeared quite normal. The amount of blood in the urine fluctuated from day to day and on Dec. 12th he was sent to a convalescent home, still passing blood.

During the following nine months he attended as an out-patient; at the end of that time his urine was clear and he was discharged. On August 22nd, 1904, the patient was admitted under the care of Dr. Percy Kidd for hæmaturia, which had recommenced on the 20th; he felt perfectly well and there was no œdema; there was no change in his condition except that the arteries were now definitely thickened; the fundi were still clear; the urine was of specific gravity 1008 and contained granular and hyaline casts, blood, and one-eighth of albumin. He was in hospital for six weeks; the urine on his discharge still contained a little blood. On Jan. 31st, 1905, the boy was brought back to the hospital; he had been feeling ill for three weeks; the first symptoms were nausea and frontal headache worst in the morning; then he began to be sick after meals and complained of pain in the epigastrium; his nose bled often during the night; he had to rise at night to pass his urine. He had not noticed any blood in his urine. On admission he was slightly anæmic and rather drowsy; there was no œdema. The pulse tension was low; the vessels were markedly thickened. The heart's apex beat was heaving in character and well outside the nipple line. Examination of the fundi showed no hæmorrhages or œdema. The urine was pale, of specific gravity 1010; it contained a trace of albumin and blood cells but no casts. The total amount of urine passed on Feb. 1st was 60 ounces. He was given a milk diet; no drugs were used except a saline purgative in the mornings. The epistaxis and vomiting continued, although the anterior and posterior nares were plugged and adrenalin was used; the bleeding was only temporarily controlled. On Feb. 5th the total amount of urine passed was only 20 ounces. Hot packs were used and pilocarpine was given subcutaneously, but there was no improvement and on the 7th he died "suddenly."

Necropsy.—At the post-mortem examination the kidneys were found to be small, equal in size, together weighing 7½ ounces; the capsule was thickened and left a granular surface when removed; the cortex was much diminished. The heart weighed 10½ ounces, the left ventricle being hypertrophied and dilated. There were no other lesions except widespread arterial degeneration.

Another case I quote in full, as I had the opportunity of seeing it while house surgeon to Mr. Fenwick.

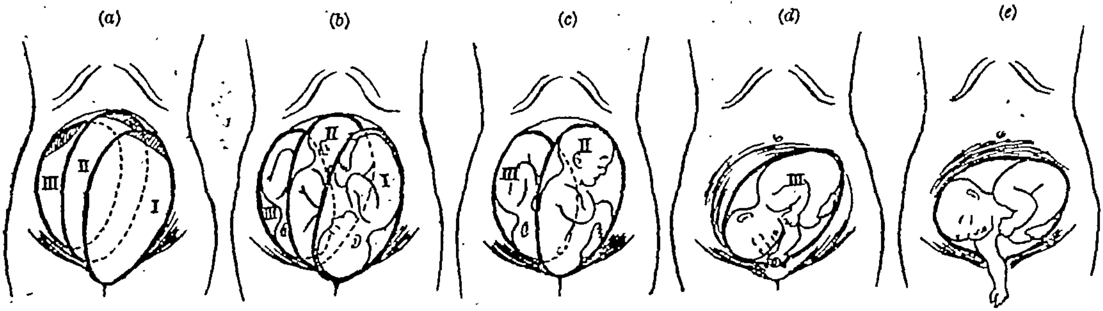
CASE 2.—A lad, aged 20 years, was admitted to the London Hospital on Dec. 11th, 1905. Three weeks before admission the patient noticed blood in his urine. There was no pain and no other trouble of any kind. The urine was the same colour throughout micturition and there was blood in it each time he passed urine; this continued until he came to hospital, the amount of blood passed gradually increasing; there were no clots in the urine. One week later pain came on in the lumbar region, usually starting in the left side, and then appearing in the right; it was worse when lying down and by night than by day; it passed forwards on the left side to the groin and along the penis, never to the testicles; it was never severe, but dull and aching in character. After the onset of hæmaturia he had to rise twice each night to pass urine. He could lie comfortably on either side as a rule, but when the pain was bad lay on the side least affected. There were no vomiting, no nausea, no puffiness of the face in the morning, and no swelling of the feet. He had had a cough for three months but there were no night sweats and he was not losing flesh. Three years previously he had a similar attack while in Russia, which lasted four weeks and was "cured by medicine." There was no history of syphilis or gonorrhœa and nothing to suggest hæmophilia. The family history contained nothing of interest.

On admission he was anæmic, but otherwise healthy in appearance. The pulse tension was higher than normal and the vessel wall was palpable. The testicles, prostate, and vesiculæ seminales were healthy. The chest and abdomen showed no abnormality. There were no retinal hæmorrhages nor œdema. Radiographs of the kidney and bladder regions were negative. The bladder was examined by means of the cystoscope and found to be healthy. The urine was smoky and red in colour, of specific gravity 1026; it contained albumin in proportion to the blood present. Microscopical examination showed the presence of blood cells, hyaline casts, and phosphatic crystals; there were no tubercle bacilli, and no bilharzia ova. The amount of urine passed in 24 hours was 52 ounces. The patient was instructed to take a mixture containing gallic acid and opium and was sent home still passing blood in his urine. On Dec. 29th he was readmitted. The hæmaturia had continued and the patient looked more anæmic. Mr. Fenwick again examined him with the cystoscope and saw blood coming from the left ureteric orifice; the efflux from the right ureter was small but clear. On Jan. 29th, 1906, he was again discharged, the urine then containing only a trace of blood. On Sept. 27th the patient returned. He had been well until two weeks accurate observation, since delivery is often partly effected by the time the medical man or midwife arrives.

The diagnosis of triplets before labour is usually somewhat difficult. Pinard relates how he recognised three distinct fœtal heads by palpation, whilst Duval heard three different fœtal hearts on one occasion. In the present case auscultation was difficult and unsatisfactory, but palpation should have given the clue to the diagnosis. The fact that the third head was hidden behind the breech of the second child made matters a little difficult. According to Edgar, 60 per cent. of triplet children present by the head, whilst the tendency to abnormal presentation is greatest in the case of the last child. This is the more readily understood when we reflect that we are dealing with an excessively distended uterus, which even when contracted down fairly well after the birth of the first two children is still likely to leave sufficient room for alterations to take place in the position of the last child. It must be rather exceptional to have, as in the present instance, vertex, breech, and shoulder presentations occurring in the same labour.

Triplets are said to occur chiefly from the twenty-fifth to the thirtieth year of life, a period which is accounted the most fertile, and during which the generative powers of a woman seem at their maximum. The mother's age, 30 years in this case, comes just at the end of this time of special reproductive activity.

The fact that the larger placenta showed a clear line of distinction between its two component parts and that one section was much smaller than the other, taken together with the observation that one child weighed a pound less than the other, leads to the consideration of the possibility of superfœtation. A tentative inquiry was put to the mother on this point, in response to which she volunteered definite and decisive information. The last menstrual period was from Nov. 13th to 18th, 1906. From that date on till March 19th, 1907 (when she first felt quickening), she was not on friendly terms with her husband and did not cohabit with him, with the single exception of Dec. 9th, 1906, on which date a temporary reconciliation took place. This date she fixed as the only possible one for insemination. The possibility of superfœtation was thus negatived and the almost exact duration of pregnancy, following on the single coitus, ascertained. Save during pregnancy and lactation the patient averred her menstrual times were always regular. One was due on Dec. 13th but was prevented by the fertilisation which must have occurred between Dec. 9th and 13th. Reckoning from Dec. 9th, 1906, to August 4th, 1907, gives the 238th day as that on which labour supervened. It is well known that labour usually comes on prematurely with triplets; but it is interesting to observe that reckoning the expected time of labour in the usual way from the beginning or end of the last menstrual period, the children would have appeared almost full time. The case therefore illustrates the large margin of error which is possible in the recognised methods of calculating the time of labour.



(a) Relative position of sacs. (b) Lie of fœtuses in utero. (c) After birth of first child. (d) After birth of second child, showing how the third infant changed position. (e) Position of third child before turning was performed.

A debateable question raised is the most favourable time for fertilisation. The current text-books say that just before or just after the menstrual period is the usual time, but most seem inclined to the view that the days following menstruation are more especially suitable. This, merely on *a priori* grounds, seems to me improbable. Given the discharge of an ovum or of a number of ova which become fertilised, I think it reasonable to conclude that the time when the mucosa is hypertrophied and engorged with blood is the most opportune for the lodgment, nutrition, and development of these ova. In this case we are provided with evidence, which seems perfectly trustworthy, to the effect that fertilisation occurred within the four days intervening between the time of insemination on Dec. 9th and the onset of the expected menstrual discharge on Dec. 13th. Triplets were the result. Neither amongst her near relatives nor those of her husband is there any other instance of multiple pregnancy—not even twins. It seems tempting to infer, therefore, that the time of fertilisation was a factor in the unusual fertility. If, as the text-books assert, the time just following menstruation is most commonly the time of conception, this case is a remarkable exception and would almost lead us to think that the pre-menstrual time is more favourable to the development of fertilised ova. It is, of course, impossible to dogmatise on such a question.

Triplets may arise from the fertilisation of one, two, or three ova. The more common origin of triplets is from two ova, one of which divides and gives rise to uniovular twins of the same sex. The rarer way was exemplified in this case, for the fertilisation of three ova was sufficiently proved. The larger placenta showed well-marked indication of being formed by the junction of two smaller ones; there were three separate cords and three complete bags of membranes. The chorions attached to the larger placenta were fused at the line of contact. The sexes of the children attached to the one placenta were different.

Quickening was first felt on March 19th, 1907. This was during the thirteenth week of pregnancy and must be considered rather early. Estimating roughly from this, the mother thought she had gone to full term.

The disposition of the parts made out by palpation before delivery, taken together with the actual mechanism as observed in the course of labour, enable us to give the lie of the fœtuses in utero and to describe how delivery was effected. I venture to give rough diagrams showing how they were situated relatively to one another. The children are numbered I., II., and III. in the order in which they were born. The fundal head and the head engaged in the pelvis were both easily made out. Probably the third head was behind the breech of the second child, for it was certainly not felt superficially. The legs of the first child and the breech of the third were very distinct, although, as said above, the true significance of the latter was not realised before labour.

The first child corresponded to a V_1 presentation. After she was born the breech of the second child quickly came down into the pelvis, and simultaneously the breech end of the third child inclined towards the mother's left side. After the delivery of the second child in the manner of a B_2 presentation, the head of the third, instead of sliding down to engage in the superior strait, hitched against the right side of the brim, whilst the breech fell still more over to the mother's left. This movement was possibly furthered by the manipulation of the uterus undertaken to prevent undue relaxation after the two children had been born. At this time the knob-like projections of limbs were palpated in the umbilical region, though the other parts of the child were not accurately made out by abdominal examination. Of course, there was now no head felt at the fundus. Finally the head slipped back completely into the right iliac fossa, the face still being anterior, whilst the right arm prolapsed outside the vulva when the membranes ruptured. A third oblique position was thus produced. The original lie of the children, therefore, was respectively V_1, B_2, and V_2, the last becoming third oblique after the birth of the other children. The unusual space left after the birth of the first two number of cases; where no changes in the fundi can be detected and the patient's general condition is good enough to warrant the administration of a general anæsthetic, operation may be advisable to check bleeding which does not react sufficiently to medical treatment.

Two methods of operation have been practised with some success. In the one, introduced by Dr. Edebohls, the capsule of the kidney is removed as entirely as possible. He even claims that this procedure has a curative effect on the nephritis itself. Four cases were treated in this way; in all the hæmaturia ceased for a time, but two relapsed within a few months. The other method is described by Mr. Fenwick. He believes that the blood escapes from the lower pole of the kidney; he therefore makes an incision into this part of the kidney substance without opening the renal pelvis. This causes a scar to form which obliterates the vessels responsible for the bleeding, and so stops it. Case 2, quoted above, is an example of this method.

Conclusions.—Renal hæmorrhage is not at all uncommon in the course of chronic interstitial nephritis and differs from other hæmorrhages occurring in the disease, as it often appears very early. This leads to difficulty in diagnosis, but may enable cases of chronic nephritis to be recognised sooner than they otherwise would be. Medical treatment is, as a rule, sufficient to control the bleeding, but recurrence is probable. Surgical treatment may be necessary in rare cases of severe hæmaturia occurring early in the disease.

London Hospital, E.

THE TREATMENT OF DISEASE AND DEFORMITY DUE TO SCAR TISSUE.

By J. SNOWMAN, M.D. BRUX., M.R.C.P. LOND.

A BRIEF moment's thought suffices to conjure up a host of lesions which may represent the remains of a subsided inflammation. Both medicine and surgery are concerned with these crippling results of injury or disease. The scar of a burn may distort the features or impede the movement of an important joint, the healing of any simple incision may be the seat of an ugly cheloid, the cure of a gastric ulcer may herald pyloric stenosis, and an adherent pericardium may remain as the permanent legacy of a departed rheumatic attack. Such troubles as these are all testimonies of a cured process of inflammation. The lessons of pathology indicate that it is not desirable to interfere with inflammatory reaction, even if we possessed the clinical means of controlling it. But it is not possible to contemplate the havoc which inflammation may leave in its train without the search for a method of alleviating it.

Surgical measures obviously present themselves as offering the prospect of remedying some deformities caused by scars. In cases where the clothes have been involved in a conflagration and the whole axilla has been burnt it occasionally happens that the arm becomes fixed to the chest-wall by adhesions. This disability can be relieved by operation—sometimes an extensive one. Scar-like bands causing intestinal obstruction likewise yield to the knife. Similarly gastric adhesions, which have been responsible for some of the most distressing forms of chronic dyspepsia, have been effectually dealt with by surgeons after laparotomy. Adhesions after injuries to joints are successfully treated by massage and passive movement.

The majority of scars concerning which advice is sought are objectionable, not because they interfere with function, but because they are disfiguring. Hypertrophic scars and cheloid may in addition be painful, but the cosmetic reasons for demanding treatment are urgent enough. The pitting of small-pox may serve as an example. Malcolm Morris [1] relates a case wherein the scarring was so extensive as to render the patient an object of horror. He was treated by inducing a strong inflammatory reaction by the application of resorcin ointment to the face. With the subsidence of the inflammation desquamation set in. The thickened borders of the scars disappeared and the pits became raised to the level of the surrounding skin, so the patient's face no longer debarred him from social intercourse. Resorcin is the type of a drug which, carefully used, sets up just enough hyperæmia to suffice for the absorption of the organised exudate in the subcutaneous tissue, but a successful result is always a problematical matter. Massage and painting with iodine are milder measures calculated to induce hyperæmia with a similar object, but with similar limitations.

There is one variety of scar tissue for which an opposite line of treatment is recommended—i.e., cheloid. This differs from ordinary scar tissue in containing an abundance of capillaries. Local treatment aims at diminishing its vascularity. To this end lead collodion, elastic pressure, deep incisions, and electrolysis are employed but with doubtful success only.

The introduction of light and x ray treatment has constituted a real advance in the therapeutics of scar tissue, more especially when it is in a thickened and hypertrophic condition. When such scars contract they give rise to most unsightly appearances and light treatment has, in numerous instances, achieved marvellous improvement or has, indeed, effected absolute cures. It is well known that the scars left when lupus nodules have been exposed to the Finsen light are smooth and soft. Experience has now shown that the exposure of hypertrophic contracting scars to the Finsen light causes an inflammatory reaction, on the subsidence of which the scars generally become flatter, more supple, and tend to vanish. X rays have also produced excellent results in the same conditions. These rays produce fatty degeneration of the cells on which they act and then apparently their absorption follows. Fibrous elements in the skin are the most difficult to influence in this way, but it seems quite clear that even fibrous tissue will undergo degeneration. An active hyperæmia is associated with this process, an exudation of leucocytes invades the cells in the scar, and they are eventually removed by phagocytosis. Light treatment, therefore, affords most benefit when it is necessary to deal with scars from a cosmetic point of view and the Finsen light is undoubtedly the method of election.

But there is yet another means of treatment which may compete with radio-therapy in the matter of results and is superior to it in that it requires no elaborate apparatus for its application. The process is merely one of hypodermic medication and the published records of the cases treated are definitely encouraging. The drug employed is fibrolysin. This is a combination of one molecule of thiosinamine with half a molecule of salicylate of sodium. For some few years past desultory references to thiosinamine have been made in papers on dermatology, in connexion with the treatment of unsightly scars, cheloid scleroderma, and lupus. It was, indeed, for the last affection that Hebra introduced the drug into therapeutics. Its constitution is indicated by the chemical terms allyl-sulphocarbamide or allyl-sulpho-urea. It is prepared from the oil of mustard and occurs in colourless crystals, is insoluble in water, and smells faintly of garlic. When used for hypodermic injections it is dissolved in alcohol. Its effects are limited to the blood-forming organs. Several hours after its injection in doses of from one to four grains the leucocytes in the blood are greatly diminished in number, falling as low as 4000 per cubic millimetre. This condition lasts, however, but a short time and is followed by a pronounced leucocytosis. While this change is proceeding a destruction and absorption of fibrous exudation and cicatricial tissue are said to occur.[2]

The claim which Hebra made for thiosinamine in the treatment of lupus was never really substantiated but the extensive clinical use of the drug has shown that there are numerous morbid conditions in which it exercises therapeutic effects of great value. These conditions are all identical in that they are the consequences of inflammatory action, but though their histology is similar they differ widely in their anatomical disposition and pathological results. Thiosinamine undoubtedly possesses a specific action on scar tissue. This obviously implies therapeutic powers of no ordinary extent, for scar tissue dominates morbid anatomy in a high degree. Scar tissue is not limited to the cicatricial fibrosis following chemical or mechanical injuries; it includes the fibrous capsules which arise from the irritation of foreign bodies, abscesses, gummata, and growths, and it embraces the fibrotic thickenings of chronically inflamed serous membranes. Indeed, nephritis and hepatitis will smoulder away only to leave the liver and kidney scarred by bands of fibrous tissue. Much of this fibrosis is protective and conservative in its function and a drug which can indiscriminately act on fibrous tissue wherever its seat and whatever its purpose may be a dangerous remedy. The softening of the fibrous content of the serum. When the patient's own cells were used, however, the result was very different. In only 19 cases were the indices between 0·8 and 1·2; 25 were below 0·8 and none was above 1·2. Still more marked was the relation of the index found when the patient's cells were used to that found when my cells were used, for the index was lower with the patient's own cells in 38 cases and higher in only four, while in two the index was the same with both the patient's cells and my cells.

---

New Cavendish-street, W.

SANITARY INSPECTORS' EXAMINATION BOARD.—An examination for certificates of qualification for the appointment of sanitary inspector or inspector of nuisances under Section 108 (2) (*d*) of the Public Health (London) Act, 1891, will be held in London on Tuesday, May 5th next, and the four following days. An examination will also be held in Birmingham in June next if sufficient candidates notify their intention of presenting themselves before May 18th. Particulars of the above examinations will be forwarded on application to the honorary secretary, the Sanitary Inspectors' Examination Board, 1, Adelaide-buildings, London Bridge, London, E.C.

"CURES" FOR ASTHMA: FATAL CASE FROM AN OVERDOSE OF OIL OF SAGE.

BY HENRY T. M. WHITLING, M.B., B.S. DURH., M.R.C.S. ENG.

ON Feb. 7th last my partner, Dr. G. D. Laing, was called at 9.30 A.M. to a woman, aged 44 years, and on his arrival found her collapsed with cardiac failure and dyspnœa, after having taken about two teaspoonfuls of oil of sage. He injected strychnine hypodermically and she rallied and appeared better before he left. Later, at 11.30, I was called to her urgently since she was much worse, and we proceeded to her house together. On my arrival I found her undressed and lying on a bed, with a deeply cyanotic face, "air-hunger," and with epileptiform convulsions. The extremities were cold, the hands being peculiarly leaden-coloured; the heart was most irregular and too erratic to be counted but very quick. Though apparently dying, as I learnt that she had not vomited, I passed down the tube of a stomach pump and extracted about one and a half pints of fluid, smelling most powerfully of the characteristic odour of sage. Then I washed out the stomach with hot water until it returned perfectly clear, and pumped 8 ounces of hot milk, white of egg, and half an ounce of brandy into the stomach. The patient was wrapped in hot blankets and given plenty of air, while my partner again injected strychnine. She, however, died in convulsions about 2 P.M. I was shown a 4 ounce bottle of oil of sage from which 2 drachms had been taken.

A necropsy, limited to the trunk, was performed by myself and Dr. Laing on Feb. 11th, and we found the heart to be normal, the muscle well developed, and no valvular disease or degeneration. The lungs were emphysematous; no tubercle was present. There was some engorgement at the bases; no bronchitis was present. The stomach was dilated; only some of the milk which had been injected was left. There was no strong smell of oil. Patchy ecchymosis was present along the greater curvature towards the pylorus; there were no ulceration, perforation, &c. In the intestines there was patchy ecchymosis of a similar character extending along the mucous membrane for from 2 to 3 feet only, and there was a strong smell of sage. The liver was normal; no signs of alcoholism were present. The kidneys were normal. The uterus was normal; the woman was not pregnant.

This woman was a sufferer from chronic asthma and had been recommended by a friend to take one drop of oil of sage, gradually increased to five drops, in two teaspoonfuls of brandy every morning for 14 days. By some blunder two teaspoonfuls of oil of sage were considered by the victim to be the dose, and the first dose taken ended fatally as above. The peculiarity of the case is that so far as my personal efforts have been able I can find no other fatal case of poisoning by oil of sage in England, though a considerable number of records have been searched. Moreover, it is extremely difficult to procure, one very large and eminent firm of chemists in the Midlands never having stocked or sold it. Sage "tea" (decoction) is generally used in the country for "fevers," "chest" complaints, and for uterine derangements. As regards the latter, it is credited with an action of an abortive, so we had to be certain that this woman was not pregnant, as in large doses of these oils there may be, and often is, an ulterior motive beyond a cure for chest troubles. In this case there was no pregnancy, nor did she or her husband ever suspect it.

The composition of oil of sage has kindly been supplied to me by Messrs. Burroughs and Wellcome, to whom I am also greatly indebted for looking up notes on its therapeutical action. I quote the following account of its pharmacology from the nineteenth edition of the "United States Dispensatory."

SALVIA (SAGE).

Both these and the flowering summits have a strong fragrant odour, and a warm, bitterish aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (J. Chem. S., 37, p. 678) found it to contain a terpene boiling at 150° C. (312·8° F.), another boiling at 171° C. (339·8° F.) thujone, $C_{10}H_{16}O$, a liquid boiling at from 197° to 203° C., and ordinary camphor, $C_{10}H_{16}O$. In the fresh oil the first terpene predominates. On standing, the amount of thujone increases, and then the camphor. The oil from the English leaves contains only a sesquiterpene $C_{15}H_{24}$, of the boiling point 260° C. (500° F.). Wallach (Ann. Ch. Ph., 1829) states that the first portions contain pinene and cineol but the greater portion consists of thujone, $C_{10}H_{16}O$ (formerly called salviol). Ferrous sulphate strikes a black colour with infusion of sage.

patients with pronounced deafness may benefit to the extent of greatly improved hearing for speech and noise, but recovery to the degree of appreciating the ticking of a watch is not to be anticipated. Tinnitus also undergoes marked diminution.

The injections of fibrolysin have occasionally been followed by temporary untoward effects. One observer has noted pyrexia, another a fall in the pulse rate. Discolouration of the skin around the puncture may persist for some weeks or a small nodule lasting about a fortnight may form at the site of injection. Some patients have complained of headache and lassitude but these symptoms disappear after a few hours. Physical weakness, even approaching to paresis limited to one or two limbs, seems to be met with at rare intervals. Some of these constitutional effects must be attributed to the pharmacological action of the drug in producing serous congestion and hyperæmia. At any rate, the onset of epistaxis or menstruation after the injection of fibrolysin, which has been noted in some instances, is explained on this assumption. On the whole, however, no more apprehension need be entertained by the practitioner who has decided to try the effect of fibrolysin in a suitable case than he would feel in the injection of diphtheria antitoxin.

Brondesbury, N.W.

LABOUR IN A CASE OF TRIPLE PREGNANCY, WITH OBSERVATIONS THEREON.

BY V. ZACHARY COPE, B.A., M.D., B.S. LOND.,
SURGICAL REGISTRAR TO THE LONDON TEMPERANCE HOSPITAL; LATE RESIDENT MEDICAL OFFICER, BRITISH LYING-IN HOSPITAL, LONDON.

THE rarity of accurate observations upon cases of triple pregnancy makes it probable that the account which follows may be of general interest. For permission to publish and for suggestions in respect of this case I am indebted to Dr. G. Drummond Robinson, physician to the Endell-street Hospital.

The patient, a married woman, aged 30 years, was admitted to the wards of the British Lying-in Hospital, under the care of Dr. Drummond Robinson, at 10.30 A.M. on August 4th, 1907. Labour had begun at 6 A.M. the same morning and was in full progress at the time of her admission. It was her sixth confinement. Ten years previously, at the age of 20 years, she had been delivered of her first child. The infant was premature and only lived a short while. Since that time she had given birth to four children at full time. Three of these were still living. The abdomen was enormously distended by an evidently abnormally large uterus. Although the patient was a multipara the skin was as tense as in a primipara and showed numerous pink "lineæ." The flanks were bulged out far back so that the general appearance resembled that caused by an excessive ascitic effusion. The superficial abdominal veins were prominent, whilst the veins of the legs were markedly varicose. By palpation a hard, freely moveable mass, which could be nothing other than a fœtal head, was felt in the left hypochondrium. On making Pawlik's grip another head was felt engaged in the pelvic brim, whilst a breech, or that which felt exactly like a breech, was palpated in the right hypochondrium. The backs of two fœtuses were made out to be lying one in each flank looking outwards. Twins were diagnosed and the conclusion was arrived at that the head engaged in the pelvis belonged to the body and breech on the mother's right, whilst the fundal head was presumed to correspond with the body on the left side of the mother. This diagnosis was upset, however, by movements both felt and seen to occur just below the fundal head on the mother's left. A knob just like a foot was felt in this situation. I then surmised that this must represent the breech end of the advancing head, thus making the first child a first vertex presentation. Consequently the fundal head was inferred to be in connexion with the fœtal back on the mother's right and it was thought possible that a mistake had been made in taking the mass in the right hypochondrium to be a breech. But the distinct gap between the fundal head and this mass was not accounted for and since the diagnosis of triplets did not occur at the time I confessed myself puzzled, but slurred over the difficulty in order to express a definite diagnosis to the midwives who were present. The observations made by abdominal palpation would, if logically followed out, have led to the correct diagnosis. The lax condition of the abdominal muscles was favourable to palpation but the passive tension caused by the excessive amount of liquor amnii largely counteracted this. Auscultation did not give much aid. A fœtal heart was indistinctly heard on each side, but the amount of fluid present prevented any accurate observations being made.

Labour pains were strong and frequent. At 11.50 A.M. a vaginal examination revealed the vertex of the first child low down in the pelvic cavity, the os uteri fully dilated, but the membranes still intact. The latter were therefore ruptured by the finger. At 11.55 A.M. a rather small female child was born in the manner corresponding to a first vertex position. A slight pause ensued and I made another vaginal examination to determine how the second child was engaging. It was found to be entering the pelvis breech first—a complete pelvic presentation. The second bag of membranes was still unbroken and was not interfered with for a few minutes in order that a pupil-midwife might also examine. Before that could be accomplished, however, strong pains returned, and about five minutes past 12 the second child was born completely enveloped in the amnion which had to be broken to liberate the infant. The placentas did not come away but still the uterus remained too large to be completely accounted for by the retention of these. Moreover, some small knob-like projections were felt by the hand which manipulated the uterus. With the idea that these might be fœtal extremities another vaginal examination was undertaken. A third bag of membranes was found presenting and the hard resistance of a vertex was felt on the right of the pelvic inlet, as if slipping down from the right iliac fossa to engage in the brim. It was announced to those present that a third child was presenting by the vertex. Progress was slow, so I examined again and found the position changed. The fœtal vertex could not now be felt but a limb was distinguished floating in the amniotic sac over the pelvic inlet. Hastily concluding this to be a foot I ruptured the membranes, when to my surprise an arm rapidly prolapsed through the vulva, whilst at the same time very strong and more painful uterine contractions supervened. Careful examination now showed the child's head to be in the right iliac fossa and the right shoulder impacted in the pelvic cavity, with the abdomen looking forward and right arm prolapsed. There seemed no prospect of spontaneous delivery despite that the child was a little smaller than usual, so an anæsthetic was administered and internal version performed. The child's left leg was brought down. The umbilical cord got caught round the limb as it descended and the leg had to be well flexed before a loop could be slipped round the knee and over the limb in order to liberate the child. Delivery was then effected without much difficulty. The infant was in a condition of white asphyxia, but revived after careful resuscitative measures. Immediately after the birth of the last child its placenta was expelled and was followed promptly by a larger placenta with two cords attached belonging to the other two children. A considerable but not excessive amount of blood was lost and the mother's condition throughout remained very good.

The first child, a girl, weighed 4 pounds 10 ounces. The second was a boy, weighing 5 pounds 10 ounces. These two were attached to a single large placenta by two separate cords. The other child was a girl, also weighing 5 pounds 10 ounces. It had a separate placenta. The larger placenta weighed 27 ounces and measured 10 inches by 7 inches. The smaller was 6 inches by 7½ inches and weighed 23 ounces; over half its circumference the membranes were attached an inch or more internal to the margin of the placental substance. The umbilical cords were 14½ inches, 18 inches, and 12 inches long respectively.

Remarks.—The occurrence of triplets is comparatively uncommon, being about once in 6000 labours in Great Britain. In Ireland and some continental countries the proportion is a little higher. Still more rarely does it happen that delivery takes place in a building where particular observation can be given to the mechanism of labour. During the last 20 years no other case has occurred in the wards of the British Lying-in Hospital, nor has there been any case of triplets at Queen Charlotte's Hospital till last month. There have been two cases since 1880 at the General Lying-in and one at the City-road Hospital during the last ten years. Cases have certainly been reported from out-patient departments but it is much more difficult to keep them under

Institute was administered, 70 cubic centimetres being injected into the flank. For the next three days the patient's condition remained practically unchanged. On the 10th the legs were not quite so rigid. He improved daily until the 25th, on which day he complained of severe pain in his wrists, elbows, and knees, which were tender and swollen. He had also a well-marked antitoxin rash and his temperature went up to 100° F. These symptoms lasted for three days and then subsided. The patient made a complete recovery.

It is interesting to note that this is the third case of tetanus which I have successfully treated with antitoxin.

My thanks are due to Dr. H. P. Potter, medical superintendent of the infirmary, for permission to publish the notes of this case.

Kensington.

A CASE OF STRANGULATED LEFT INGUINAL HERNIA CONTAINING CÆCUM AND APPENDIX.

BY C. E. RUSSEL-RENDLE, F.R.C.S. EDIN.,
ASSISTANT SURGEON, SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A MALE infant, nine months old, was admitted into the South Devon and East Cornwall Hospital on April 23rd, 1907, with a strangulated left inguinal hernia. There was a history of a "lump" occasionally visible in the left groin for some two months previously; four days prior to admission it had failed to disappear and the child had been taken to the out-patient department where the hernia had been reduced. On admission there was a fairly large lump on the left side of about the size of a bantam's egg, presenting the usual signs of strangulation. This had lasted for five hours. Under chloroform the usual operation was undertaken. The first loop of bowel that appeared was small intestine but more remained behind, which on investigation proved to be part of the cæcum with an appendix nearly three inches long showing signs of previous inflammation. The appendix was removed, the bowel was reduced, and the canal was closed with mattress sutures of chromic gut. The patient went out perfectly healed on May 30th. Three weeks later he was readmitted with a hernia (not strangulated) on the opposite side. There had been no previous history nor had any signs of a hernia been seen during his stay in hospital. A radical cure was performed on June 24th and the child left the hospital three weeks later. Both herniæ were of the acquired variety, neither testis being seen, but each in its proper place in the scrotum.

Remarks.—A left-sided hernia of cæcum and appendix is an extremely rare condition, especially in so young an infant, and on this account I thought the case worth recording. In 1891 a case of appendix and cæcum in a left femoral hernia in a woman, aged 58 years, occurred in St. Bartholomew's Hospital, and is recorded in Vol. XXVII. of its reports. Mr. W. McAdam Eccles also quotes a case under the care of Thiery where the appendix alone was found in the left inguinal hernia in a male, aged 58 years, but these are the only two cases that I can find. There was no transposition of viscera and therefore I assume that the meso-cæcum was unusually long, although I could not demonstrate it at the operation. It was curious, also, that a hernia should develop on the opposite side so suddenly and so soon after the first one had been dealt with.

Plymouth.

ROYAL INSTITUTION.—The following are among the lecture arrangements after Easter: Professor F. T. Trouton, two lectures on (1) Why Light is Believed to be a Vibration, and (2) What it is which Vibrates (experimental course); Professor William Stirling, two lectures on Animal Heat and Allied Phenomena; Mr. W. Bateson, three lectures on Mendelian Heredity; and Dr. Alexander Scott, three lectures on the Chemistry of Photography (experimental course). The Friday evening meetings will be resumed on May 1st, when Professor Joseph Larmor will deliver a discourse on the Scientific Work of Lord Kelvin (with experiments and typical apparatus illustrative of his discoveries and inventions). Succeeding discourses will probably be given by, among others, Dr. J. Y. Buchanan, Dr. H. T. Bulstrode, Professor Kapteyn of the University of Groningen, and Professor Sir James Dewar.

ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Hypnotism.

A MEETING of this section was held at the Apothecaries' Hall, Blackfriars, on March 24th, Dr. T. E. BURTON BROWN, the President, being in the chair.

Dr. JOHN MILNE BRAMWELL delivered an address on Hypnotism. He described the gradual evolution of hypnotic theory from the time of Elliotson and the later mesmerists to the present day. Mesmerism, Dr. Bramwell pointed out, was the first anæsthetic, and hypnotic anæsthesia was still occasionally induced at the present day. At the same time he regarded this as being more of scientific than practical interest, for only a limited number of persons could be hypnotised deeply enough for operative purposes. Dr. Bramwell gave an account of his own work and drew attention to the fact that formerly his proportion of successes had been greater when he was able to choose his cases from amongst the patients of his own general practice. At present, when the cases sent to him were almost invariably long-standing ones in which other methods of treatment had been tried without success, his difficulties were considerably increased. Still, even in such cases, success was often striking and sometimes rapidly obtained. Dr. Bramwell described the methods which he adopted. He rarely found it necessary to induce deep hypnosis, but a restful, drowsy state seemed to favour the action of suggestion. Why suggestion administered in this form acted with more force than the suggestions of ordinary life he was unable to explain adequately, but the fact that this was the case came under his daily observation.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on April 3rd, Dr. JAMES BARRY BALL, the President, being in the chair.

The following cases and specimens were exhibited:—

Dr. W. JOBSON HORNE: An Autograph Letter by Johann Czermak.

Dr. JAMES DONELAN: 1. A Swelling of the Right Vocal Cord with a Projection at the Left Vocal Process in a phthisical woman. 2. Two cases illustrating the Effects of Neglected Adenoids.

Dr. STCLAIR THOMSON: Two radiographs showing the Value of X Rays in Sounding the Frontal Sinus. In one radiograph the probe had entered an ethmoidal cell; in the other it was, with the help of the x rays, passed correctly into the frontal sinus.

Dr. J. DUNDAS GRANT: A case of Thyrolingual Fistula successfully treated by electrolysis and excision; it had twice recurred after excision alone.

Mr. H. BETHAM ROBINSON: A specimen of Pedunculated Lymph-angeioma removed from the anterior commissure of the larynx of a man aged 35 years.

Dr. R. H. SCANES SPICER: A case of Papilloma of the Left Vocal Cord in a man aged 76 years.

Dr. A. STANLEY GREEN and Dr. H. LAMBERT LACK: A Smooth Red Sessile Growth, considered to be a tuberculoma, springing from the posterior laryngeal wall below the cords in a phthisical woman.

Mr. C. A. PARKER: A case showing great Nodular Infiltration of the Septum and Outer Wall of Both Nares of Uncertain Causation.

Dr. DAN MCKENZIE: A Suppurating Hæmatoma of the Septum, with a Fistulous Opening into the Gingivo-labial Fold.

Mr. P. R. W. DE SANTI: A case of Bilateral Swelling of the Septum Nasi.

Mr. W. H. KELSON: Bony Outgrowths from the Maxilla and Mandible in a man, aged 30 years. The case was generally considered to be one of leontiasis ossium.

Mr. CYRIL A. B. HORSFORD: A new instrument for passing a suture through the epiglottis to facilitate intralaryngeal operations.

Dr. H. J. DAVIS: 1. A case of Fibroma at the Junction of combined with the manipulation of the uterus through the abdominal wall were contributing factors in the change of position. Children V_1 and B_2 had a conjoined placenta. The change in position of the third child was most probably the reason why this large placenta came away last of all.

The puerperium was uneventful. The uterus involuted quite normally. The lax condition of the abdominal walls after delivery was very remarkable. Puerperal complications are said to occur more commonly in the case of triplets. This is probably because of the unusual strain on the mother and the liability to complications during the labour. No collapse occurred after labour, although such an enormous reduction in the intra-abdominal tension had taken place so comparatively suddenly. I believe that it is in these cases that the application of a firm binder is more especially useful in averting collapse.

In cases of triplets the children are often very premature and many are stillborn. The fœtal mortality (according to Edgar) is about 31 per cent. The children delivered at this labour were certainly slightly premature but they all thrived very well after birth. However, I have recent information that one child died when two months old from broncho-pneumonia. The other two are in splendid condition.

Bessborough-gardens, S.W.

NOTE ON AN ABNORMALITY OF THE LIVER SIMULATING A THORACIC TUMOUR.

By E. A. ELDER, M.A., B.Sc., M.B., Ch.B. Edin.,

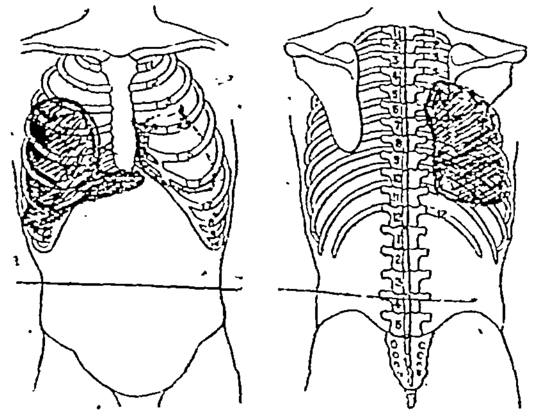
AND

J. M. POSTLETHWAITE, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.,

HOUSE SURGEONS, BLACKBURN AND EAST LANCASHIRE INFIRMARY.

THE patient, a man, aged 57 years, was admitted to the Blackburn and East Lancashire Infirmary on the evening of Dec. 16th, 1907, partially unconscious and suffering from dyspnœa. He had been working up to three days previously. The history of the illness was that on Dec. 13th while stretching up to the mantelpiece he was seized with sudden pain in the chest and with shortness of breath.

On admission he was suffering from severe dyspnœa and had a pulse rate of 106, his temperature being 101·6° F. The lungs produced a highly resonant note on percussion, except on the right side, where an area of dulness extended from the second interspace to the costal margin in front and going as high as the spine of the scapula behind. Over the dull area was an absence of breath sounds, of vocal resonance, and vocal fremitus, but harsh vesicular breathing, accompanied by numerous crepitations and a few sibilant rhonchi, could be heard over the rest of the lungs. The heart appeared to be enlarged; the apex beat was at the level of the sixth rib, half an inch outside the nipple line. The heart sounds were muffled and considerably masked by respiratory sounds. The legs were œdematous up to the knees. There was no albumin in the urine. The patient was restless and irritable and apparently unable to answer questions. He gradually lost consciousness and died on Dec. 18th.



Rough diagram to illustrate area of absolute dulness on the right side of chest. The shading should have extended up to the lower border of the second rib in front.

A post-mortem examination was made. On opening the right thoracic cavity a large, smooth, rounded tumour was seen projecting up through the right side of the diaphragm into the thoracic cavity and displacing the lower and middle lobes of the right lung, which were collapsed and shrunken into a very small size. The lower and middle lobes were pushed up by the tumour into the upper and back part of the right thorax against the upper lobe which was emphysematous. The upper convex surface of the tumour was covered by the diaphragmatic pleura and reached to the level of the second rib. The inferior surface forming the base was slightly concave and rested upon what was apparently the liver beneath it but at the same time was attached all round to the remainder of the diaphragm. On opening the abdomen the liver was seen in its usual position but seemed to be of unusual shape and to be minus the gall-bladder. It extended from the right hypochondrium almost to the left but no division into the right and left lobe could be discerned. After removing the organ from the abdominal cavity the gall-bladder was observed lying behind it and connected with the thoracic tumour which on section was found to consist of liver substance. These two liver masses were connected by a duct from each, which joined to form a common duct leading to the duodenum. A third small lobe of liver substance was found situated above on the left extremity of the lower lobe, being connected to it by a very narrow neck of liver tissue and surrounded by a fold of peritoneum. The weight of the tumour was 38 ounces, the smaller mass 23 ounces, and the smallest three ounces. The heart: the pericardium was adherent and very much thickened. The right auricle and ventricle were filled with ante- and post-mortem clots. The tricuspid valve admitted four fingers to the middle joint; there were old vegetations on the valve. The left ventricle was hypertrophied. The aortic valves were apparently normal. The lungs: on the right side the pleura was slightly adherent to the chest wall. The lower and middle lobes were collapsed, the upper being emphysematous. On the left side the pleura was extensively adherent to the chest wall. The lung was emphysematous, the lower lobe being œdematous. The spleen was very small; it measured three inches by one inch.

We are indebted to Dr. M. Bannister for his kind permission to publish this case.

Blackburn.

THE CELL AS A FACTOR IN PHAGOCYTOSIS.

By H. WANSEY BAYLY, M.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.,

ASSISTANT IN THE BACTERIOLOGICAL DEPARTMENT OF ST. GEORGE'S HOSPITAL; DIRECTOR OF THE OPSONIC DEPARTMENT OF THE CLINICAL RESEARCH ASSOCIATION.

(From the Bacteriological Department, St. George's Hospital.)

IN the paper on Phagocytosis read before the Medical Section of the Royal Society of Medicine on March 25th[1] Mr. S. G. Shattock and Mr. L. S. Dudgeon emphasised the importance of the rôle of the cell and demonstrated that it, as well as the serum, played a part of some importance. In July, 1907, with the view of endeavouring to ascertain whether fatigue lowered the power of resistance to infection by acting on the cell or the serum, I made 88 determinations of the tuberculo-opsonic index of 44 women in labour in Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W. As the observation seems to suggest that the lowered resistance to infection in women during and immediately after labour may be due at least in part to want of avidity of the cell, I have thought that it might be of some interest to those who heard, or have since read, the interesting paper mentioned above.

With each patient's serum I made two determinations of the tuberculo-opsonic index, in the one case using the patient's own cells and in the other using my cells. I found, using my own cells, that in 39 cases the index was between 0·8 and 1·2. Of the remaining five cases three were above 1·2 and only two below 0·8, thus confirming Dr. G. T. Western's conclusion that fatigue does not lower the opsonic resolving lobar pneumonia, was studded with small abscesses, and showed typical septic broncho-pneumonia; the pus of the abscesses showed the same organism. The origin of the trouble was the bladder. It was the first instance in which he had found the staphylococcus aureus producing the particular group of symptoms.

---

[1] THE LANCET, March 28th, 1908, p. 933.

Dr. HARVEY exhibited specimens of Infective Mouse Tumours which were obtained originally from Dr. E. F. Bashford of the Cancer Research Laboratory and had been transplanted for five or six generations. They grew successfully in from 40 to 60 per cent of the mice inoculated. The tumour was found normally in mice; one tumour would be sufficient to inoculate 100 mice. The transplantations were generally difficult and it took some time for the tumour to accustom itself to the new race. In one case a tumour worked its way through the ribs.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on March 27th, Dr. A. J. Wallace (Liverpool), the President, being in the chair.—A vote of condolence to Mrs. William Walter of Manchester on the death of her husband was moved by Mr. R. Favell, seconded by Dr. D. Lloyd Roberts, and supported by Dr. J. E. Gemmell and Dr. Martin, and was carried.—Dr. Miles H. Phillips (Sheffield) exhibited a specimen of Uterus Bicornis Unicollis, with atresia of the external os and absence of the vagina. The patient, aged 16 years, had enjoyed good health up to October, 1907, when she began to suffer from pain in the right iliac region, accompanied by some febrile disturbance. She had never menstruated. The specimen was removed by operation. Recovery was uneventful.—Dr. Lloyd Roberts (Manchester) showed a Vaginal Fibroma removed from a patient, aged 46 years, who had had six pregnancies. The labours had always been difficult. She complained of pain and difficulty in micturition and an irregular sanious vaginal discharge. The tumour, which had a sessile attachment to the left fornix of the vagina, was removed by enucleation.—Dr. H. Briggs (Liverpool) communicated a case of Acute Complete Inversion of the Uterus treated by manual reduction on the twentieth day after labour. The patient, aged 28 years, married four years, had had two miscarriages previously to the present full-term pregnancy. The labour was slow on account of premature rupture of the membranes and the delivery by forceps under chloroform occupied two hours. During the third stage fundal pressure had been used on account of severe hæmorrhage. For three weeks the patient had been nursed at home by a friend, during which period there had been febrile disturbance, the temperature being from 101° to 105° F., with a definite rigor on the day before admission to hospital, severe abdominal pain with profuse vaginal bleeding, dribbling and incontinence of urine. The catheter had been repeatedly used and a vaginal douche of lysol twice daily. No vaginal examination was made till the nineteenth day, when she was at once removed to hospital. On examination the enlarged inverted uterus lay in the vagina, its mucosa was slightly ulcerated, and the ring of cervix above was faint and sharp. Under ether the well-marked uterine cup became palpable bimanually and reduction was effected by continuous increasing pressure gradually exerted so as to raise the body of the uterus through the thin cervical ring without damage. A douche of sterilised water at 120° was then used. The reduction occupied 20 minutes. For the first seven days intra-uterine douches of sterile water were given twice daily. Convalescence was tardy, with febrile symptoms, the temperature being from 101° to 105°, including six rigors during the first three weeks. The patient left hospital eight weeks after the reduction of the inverted uterus.—Dr. Briggs and Dr. J. F. Edmiston narrated a case of Severe Concealed Accidental Hæmorrhage occurring in a patient, aged 26 years, 5-para, with a history of easy labours previously. At 11.30 A.M. on March 6th, 1908, three days short of the full term, the patient was seized with severe abdominal pain and vomiting. At 7.30 P.M. the collapse became grave; she was pallid, cold, and restless, with a thready intermittent pulse of 152, and a subnormal temperature. The physical signs of a tense, tender, full term uterus were present. Fœtal heart sounds were inaudible. Vaginally the cervix admitted two fingers, there was no bleeding, and the examining finger could reach neither placenta nor blood-clot. The membranes were unruptured and labour pains were absent. In this condition she was admitted to hospital and Dr. Briggs ordered $\frac{1}{4}$ grain of morphine and $\frac{1}{100}$th grain of atropine hypodermically at 9.30 P.M. This was followed by five hours' sleep and at 8 A.M. on March 7th the pulse had fallen to 120. Three hours later the same dose of morphine and atropine was repeated on account of restlessness, and sleep supervened. During the intervals of sleep small quantities of milk and soda-water, or milk and barley-water, were taken. The os now admitted three fingers. Shortly after midnight labour pains became pronounced and a speedy and spontaneous delivery was completed by 12.30 A.M. on March 8th. 2½ pounds of clot and about a pint of liquid blood were expelled. The fœtus, which appeared to have been dead about one week, weighed 7¾ pounds.—Dr. Phillips also related a case of Concealed Hæmorrhage during the Fifth Month of Pregnancy treated by vaginal hysterotomy. Recovery was good. The blood apparently occupied the decidual space and the amount of clot collected filled a two-pint measure.—Dr. Gemmell read a note on Primary Carcinoma of the Fallopian Tube based upon a recent case in which there was a history of profuse watery offensive vaginal discharge in a multiparous woman, aged 45 years. The physical signs led to a diagnosis of multiple fibroma uteri, with chronic inflammatory disease of the right appendage. Laparotomy revealed double chronic inflammatory appendage disease; right hydrosalpinx, left pyosalpinx. Subsequent examination of the specimen demonstrated that the left tube, which was closed at its fimbriated end, sausage-shaped, measuring three inches in diameter at the abdominal end and one inch at the uterine, contained pus and an enormously thickened mucous membrane, forming a papillomatous growth, microscopic sections of which showed the papillomatous growth to be adeno-carcinoma. Both ovaries were normal; the right tube showed simple salpingitis.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the anatomical department of Queen's College, Belfast, on March 26th.—Professor J. Symington showed, by means of the lantern, a reconstruction to illustrate the Relations of the Deeper Parts of the Brain to the Lateral Aspect of the Skull, and specimens illustrating Dental Anatomy with X Ray Photographs of Developing Teeth, taken by Dr. J. C. Rankin.—Dr. P. T. Crymble demonstrated specimens of the Central or Rolandic Fissure of the Cerebrum, as well as various pathological specimens.—Dr. Thomas Killen and Dr. W. J. Maguire showed specimens of the Spinal Cord and Mid-brain to illustrate the order of medullation of fibres.—Mr. H. H. B. Cunningham showed specimens of Membrana Tympani and Tympanic Recesses.—Professor T. H. Milroy made a communication on Colour Fatigue.—Dr. J. A. Milroy showed a series of slides illustrating the microscopic structure of some of the organs of special sense.—Professor W. St. Clair Symmers and Dr. W. J. Wilson gave an account of (*a*) Agglutination of Organisms of the Typhoid, Colon, and Alkaligenes Groups by the Blood Serum of Cerebro-spinal Fever Cases; (*b*) Cerebro-spinal Meningitis due to infection with the typhoid bacillus, Gärtner's bacillus, and the anthrax bacillus; (*c*) Fermentative Powers of the Meningococcus and Gonococcus; and (*d*) Certain Differences between Young and Old Cultures of Meningococci.—Dr. Wilson also made communications on (*a*) Cerebro-spinal Meningitis due to infection with the micrococcus catarrhalis; (*b*) note on the occurrence of Gram-negative Cocci in Fæces; and (*c*) Pleomorphism exhibited by Gram-negative Cocci of the Catarrhalis (allied to influenza) Class.—Dr. Wilson and Dr. E. H. M. Milligan gave an account of an investigation of the Etiology of Typhus Fever by Blood Culture Methods.—Dr. D. P. Gaussen and Dr. T. Houston gave an account of a case of Streptococcic Septicæmia successfully treated by a vaccine prepared by Dr. Houston.—Dr. Houston and Dr. Rankin gave a demonstration of the Reaction of Meningococcic Serum.—Sir John Byers showed: (1) a Uterus with Tuberculous Pus Tubes removed from a young unmarried woman, aged 25 years; (2) Five Uteri with Fibro-myomata removed by Hysterectomy; (3) a Uterus with a Fibroid Tumour attached to its posterior wall and protruding partially into the Uterine Cavity removed by Hysterectomy (patient aged 50); (4) a Molluscum Fibrosum Tumour removed from the Clitoris; (5) a Fibro-cystic Uterine Tumour removed by Hysterectomy; (6) an Ovarian Tumour; and (7) a Hydrosalpinx and other Tumours of the Female Pelvic Organs. Sir John Byers also showed a series of Stereoscopic Photographs of Obstetric Conditions.—Dr. C. E. Shaw showed a water-colour drawing of Melanoma

Uses.—Sage unites slightly tonic, astringent, and aromatic properties. By the ancients it was highly esteemed; it is at present little used, except as a condiment, but has been given in dyspepsia, also for colliquative sweats. The dose of the powdered leaves is from 20 to 60 grains (1·3 to 3·9 gm.). Dose of the infusion (1 oz. in 1 pint of boiling water), 2 fluid ounces (60 c.c.). According to Cadeac and Meunier (Lyons Med., May, 1891) the *volatile oil of sage is a violent epileptiform convulsant*, resembling in its action the oil of absinthe, but less powerful.

Dose.—From 20 to 60 grains (1·3 to 3·9 gm.).

The features of poisoning in this case are apparently characteristic of all essential oils. There appears strong inhibition of the pneumogastric nerve, resulting in a weak, feeble, and irregular heart beat and dyspnœa, these oils acting through the medulla. Epileptiform convulsions also arise and in this case became stronger before death. (Oil of eucalyptus likewise causes them.) The cyanosis was remarkable, however, and was most noticeable in the hands. Of all organs the *lungs* smelt most powerfully of sage. There was only that amount of ecchymosis in the stomach and intestine which would be expected from any irritant, as a volatile oil would be in such a dose; there was no erosion or perforation. In the *Lyons Médical* for May, 1891 (U.S. Dispensatory), M. Cadeac and M. Meunier report that five centigrammes of *essence* of sage injected intravenously into a dog produced epileptiform convulsions, and that 70 centigrammes (about 10½ grains) injected into a dog weighing 21 kilogrammes caused death after 35 epileptiform fits. The ordinary essence contains a proportion of 1 of oil in 4 of spirit (1 in 5), so that if 70 centigrammes of *essence* caused death in a dog of 21 kilogrammes (46 pounds) it would only be receiving intravenously a dose of about two minims. The woman weighed about 9½ stones (133 pounds), so that injected intravenously we might expect a dose of six minims to be fatal. In this case about 120 minims were taken and proved fatal, which, allowing for the difference between intravenously and per *os*, is a dose probably considerably over the amount necessary to cause death. From 30 to 40 drops by the mouth would generally cause severe symptoms, if not death, judging by the above experiment.

The oil which was the cause of this woman's death had in the first instance been imported from Austria. This is worthy of the remark that the English salvia officinalis only contains a sesquiterpene $C_{15}H_{24}$, whilst foreign salvia contains two terpenes, thujone $C_{10}H_{16}O$, and camphor $C_{10}H_{16}O$. The oil was analysed by two independent analysts (Messrs. Harvey and Wilkin and Mr. J. R. Richardson, Leicester) and was found normal. The specific gravity was 0·9229. Optical rotation + 13·6° in 100 millimetres. Two volumes of 80 per cent. alcohol, soluble.

It is a sad example as to how the public lose their lives in endeavouring to "cure" themselves by using "old women's" remedies and "quack" medicines instead of attempting to obtain relief through the proper and more scientific channels. This genuinely comes under the first head, the deceased having obtained her muddled-up "prescription" through a neighbouring old woman.

Husbands Bosworth, Rugby.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF INJURY TO THE BLADDER DURING AN OPERATION ON A STRANGULATED FEMORAL HERNIA.

BY T. P. LEGG, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL FREE AND ITALIAN HOSPITALS; SURGICAL TUTOR AT KING'S COLLEGE HOSPITAL, LONDON.

A WOMAN, 33 years of age, was admitted to the Royal Free Hospital on Oct. 1st, 1904. For six years she had suffered from a femoral hernia for which a truss had been worn. During the last two years the hernia had been irreducible but had given rise to no other symptoms, and she had continued the use of the truss. On Sept. 26th she went for a long walk. On the next day vomiting began, accompanied by intense abdominal pain. The hernia increased in size and these symptoms persisted till she was admitted. For some years she had occasional frequency of micturition. She had been married three years and had two children. The hernia was larger during each pregnancy, and after the birth of the first child she had prolapsus uteri. On examination a strangulated left femoral hernia was found. The swelling measured 2½ or 3 inches in diameter; the skin over it was somewhat reddened. The abdomen was a little distended and peristalsis of the intestine was visible.

Operation was at once undertaken. In opening the sac, which was very thin, the intestine was incised. The wound was sewn up at once by a double row of continuous sutures. The stricture having been divided the intestine was replaced in the abdominal cavity. Whilst the sac was being dissected from its surroundings a cavity, lined by mucous membrane, was opened on the inner side of the sac. No urine escaped, but on passing a catheter per urethram it was quite evident that the bladder had been cut into. A little careful dissection made it possible to free the prolapsed portion of the bladder from the outer surface of the sac as high as its neck, which was then transfixed and closed in the usual manner. The aperture in the bladder was closed by a double row of sutures, care being taken that the inner row did not penetrate the surface of the mucous membrane and that the cut edges of the latter were brought into apposition. The prolapsed portion of the bladder was then replaced in the abdominal cavity and the hernial ring partially closed, a small drainage-tube being passed through it into the sub-peritoneal tissue. The external wound was sutured except where the tube came through.

The abdominal pain and vomiting ceased at once and the bowels were opened on the fourth day. For the first two or three days the urine contained some blood; at the end of a week the urine was normal. Slight suppuration occurred in the wound, but there was no rise in temperature and the highest pulse-rate recorded was 100; generally the pulse was 84 per minute. There was no escape of urine through the drainage-tube. The patient left the hospital on Oct. 22nd quite well except for a small sinus, from which a stitch was subsequently extracted. The wound then healed soundly.

There was nothing to suggest that the bladder was prolapsed through the crural canal and was adherent to the outer surface of the sac till it was opened. No unusual amount of thickening was detected and the wall of the prolapsed portion was not abnormally thick. A large portion of the bladder was prolapsed, because the cavity opened was very large and the catheter passed straight into it. The history of the prolapsus uteri is interesting, but whilst the patient was in the hospital and when seen afterwards there did not appear to be any such descent of the uterus. It is interesting also to note that the hernia became larger during each pregnancy and had been irreducible for two years. Possibly the pregnancies caused the bladder to prolapse through the crural ring and the irreducibility was due to the bladder coming down outside the sac. There was no suggestion that the size of the swelling varied according to the amount of urine in the bladder, and, as already stated, no urinary symptoms except occasional frequency of micturition were present.

Harley-street, W.

NOTE ON A CASE OF TETANUS SUCCESSFULLY TREATED WITH ANTITOXIN.

BY J. BASIL COOK, M.D., CH.B. VICT., D.P.H. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, KENSINGTON INFIRMARY.

THE patient in this case was a man, 64 years of age, who was admitted into Kensington Infirmary on August 5th, 1907, suffering from tetanus. The history was to the effect that he had to leave his work on July 31st owing to severe pain in the jaw and inability to open his mouth. On admission he presented an absolutely typical risus sardonicus. His teeth were tightly clenched and there were twitchings of the facial muscles. There was marked opisthotonos, the muscular rigidity being so great that by lifting the feet the whole of the body, with the exception of the head, could be raised from the bed. The arms were unaffected. Fluids only could be swallowed. There was a small abrasion on the left foot. The patient was quite conscious, he was perspiring freely, and his temperature was 98° F. He was given 15 grains of chloral hydrate and 15 grains of potassium bromide every four hours. On August 6th antitetanic serum obtained from the Pasteur the illness when double optic neuritis, pyrexia, paralysis of one external rectus and a misleading history of otorrhœa suggested a latent cerebral abscess. Relief of tension thus brought about greatly assisted recovery. In two out of the three cases no pregnancy existed and Dr. Parry-Jones urged that lumbar puncture or trephining must be resorted to when necessary.—The paper was discussed by the President, Dr. C. H. Cattle, Dr. Jacob, Mr. W. Tibbles, Dr. A. J. Sharp, and Dr. Thompson, and Dr. Parry-Jones replied.—Dr. Cattle read notes of a case of Embolism of the Abdominal Aorta occurring in a man, aged 39 years, the subject of mitral stenosis. It was probable that embolism of the right common iliac artery occurred six days before the graver event and led up to it, as pain occurred in the iliac region accompanied by a rise of temperature to 101° F. Later paralysis and anæsthesia of both lower extremities occurred with absence of patellar and plantar reflexes, then livid mottling of the inner side of the right thigh, and both limbs became pulseless. Hæmaturia and albuminuria also ensued and death occurred a day later. The case was discussed by the President and Dr. J. Watson.—Dr. Parry-Jones related a case which had come under his notice and ended fatally ten days after the onset, and Dr. Cattle replied.—Dr. Sharp showed two specimens of Psammoma from the choroid plexuses of the brain with microscopic sections.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on March 25th, Dr. Justin M. McCarthy, the President, being in the chair.—Mr. H. Gilbert Barling and Dr. A. Stanley Barnes showed a man who had been successfully operated on for Cerebral Tumour.—Mr. Barling showed a middle-aged man upon whom he had performed Interscapulo-thoracic Amputation for a mixed round- and spindle-cell periosteal sarcoma developing the upper two-thirds of the humerus and encroaching slightly upon the capsule of the shoulder-joint. The patient has remained free from recurrence. He mentioned that he had resorted to this amputation in three other cases of sarcoma of bone, all the patients recovering from the operation. The first patient suffered from a myeloid sarcoma of the humerus of four years' duration and generalisation of the growth occurred a few months after operation. The second case was that of a girl with a fungating myeloid sarcoma of the scapula. This patient remains well eight years after the amputation. The third case was that of a girl with a periosteal round-celled sarcoma of the supraspinous portion of the scapula. This patient remains well two years and three months after the amputation.—Mr. Barling also showed a boy in whom he had excised the upper third of the humerus for an early Myeloid Sarcoma which had produced spontaneous fracture. It was still practically confined within the limits of the bone. The operation was performed 15 months ago and the patient remains quite well.—Mr. Jameson Evans showed a man whose condition was regarded as one of Infantilism, with some superadded Intracranial Lesion.—Dr. Smallwood Savage showed a specimen of an Unruptured Tubal Molar Pregnancy, diagnosed before operation. Pathologically the right Fallopian tube was seen to be swollen about the middle of its length by a fusiform bulging. The fimbriated extremity was seen to be patulous. The ovary was enlarged by a follicular cyst of the size of an egg. The special point of interest in the specimen was to be seen in the section of the tube at the site of the swelling, for both by the naked eye and by microscopical section the tubal mole was shown to be situated in the tubal wall and outside the lumen. The explanation of this condition was to be found in the trophoblast of the growing ovum, which, by its eroding action on the maternal tissues, had travelled from inside the lumen, at the site of its implantation, into the muscularis and between the external and internal layers of muscle. It is generally held that the trophoblastic action is invariably the essential cause of the rupture of a tubal pregnancy, as it has been shown by the imperfect decidual production in the tube that the maternal resistance to the trophoblast is weak. Good recovery followed.

HUNTERIAN SOCIETY.—A meeting of this society was held on March 25th, Mr. F. Rowland Humphreys, the President, being in the chair.—Dr. J. H. Sequeira gave a demonstration of patients illustrating various forms of Tuberculosis of the Skin. He divided the cases into two groups—those in which the tubercle bacillus had been demonstrated and those which were believed to be due to circulating toxin produced at some distant tuberculous focus. The first group was illustrated by cases of lupus vulgaris of the skin, nasal mucous membrane, palate, and tongue; by scrofulodermia following caries of the teeth and mandible with sinus. He also showed a case of pseudo-elephantiasis of the leg with tuberculous lymphangitis and an interesting case of verruca necrogenica, infected probably from tuberculous meat. In the second class, the so-called tuberculides, he showed a case of lichen scrofulosus in a patient suffering from lupus of long standing; a case of symmetrical necrosing tuberculides—acnitis and folliculitis of some authors; and one of erythema induratum of Bazin.—Dr. W. Langdon Brown and the President discussed the cases.

ERRATUM.—The word "purpose" should be substituted for *operation* in the second resolution passed by the Medico-Legal Society on March 24th, and reported in our last issue (p. 1008).

Reviews and Notices of Books.

An Introduction to Child Study. By W. B. DRUMMOND, M.B. Edin., F.R.C.P. Edin., Assistant Physician to the Royal Hospital for Sick Children, Edinburgh. London: Edward Arnold. 1907. Pp. 348. Price 6s. net.

The Child's Mind: its Growth and Training. By W. E. URWICK, M.A. London: Edward Arnold. 1907. Pp. 269. Price 4s. 6d. net.

WE take these two works together, for they are in a certain sense complementary. By child-study is meant the study of children by the methods of modern science. It has most important bearings upon social and political questions. The real aim of education should be not mere instruction in subjects but the development of the mind. Herbert Spencer reproached the Englishman or studying his horses and neglecting his children but it appears that in 1570 Roger Ascham made use of the same comparison. After Dr. Drummond has dealt with the kind of preparation required by the person who pursues child-study and has given certain cautions in carrying on the study there are interesting chapters on biology and child study dealing with the consciousness of children, evolution, and Darwinism in the nursery. The last is illustrated by traces of our prehuman ancestors still surviving in the nursery and even persisting to a later period, what are called the monkey traits of children, e.g., the movements of the thumb, the furrow or flexion fold on the sole of the foot in children, the turned-in position of the feet at birth, the clasping and climbing power, and many innate and hereditary instincts. As to the methods themselves history and literature help. There is the approach through educational theories and methods but the chief is the direct study of children themselves, and this may be done by (1) biographical studies of individual children; (2) anthropometric methods; (3) experimental methods; (4) direct questioning; and (5) the syllabus method. Dr. Drummond provides such a syllabus for testing the observing powers, memory tests—visual imagery—money sense, vocation, ideals, reasoning powers, and so on (pp. 86–92). Full directions are given as to how to study a baby (pp. 93–108) and these seem to be full and explicit. Then follows a chapter on the weight of babies and a most interesting one deals with some facts of growth. There is a careful account of the senses and the nervous system and the health of the child, and an important chapter on fatigue embodies the results of Mosso's investigations. The instincts and interests of children are discussed in a thoroughly interesting manner, while under "forms of expression" the leading facts of the physiology of speech—or baby linguistics—are set forth. The moral characteristics are dealt with, and finally there is a discussion on religion and the child and on peculiar and exceptional children. Obviously the author is in love with his subject and he sets forth his ideas in a clear, precise, and convincing form.

the Posterior and Middle Thirds of the Left Vocal Cord. 2. A case of Cyst on the Floor of the Nose.

Mr. HERBERT TILLEY: A case showing the result of Killian's Operation on the Right Frontal Sinus, and of an Incomplete Killian's Operation on the Left.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens, &c.—Tuberculous Salpingitis.

A MEETING of this section was held on March 13th, Mr. E. H. TWEEDY, the President, being in the chair.

Mr. J. SPENCER SHEILL exhibited an Abnormal Placenta which showed a raised ring forming a complete circle about half way between the margin and the insertion of the cord, about two centimetres in depth and half that in thickness. The membranes were adherent to the margin of the placenta.

Dr. HENRY JELLETT exhibited a Table for Estimating the Date of Delivery from the Size of the Uterus. It was not, he said, intended for perfect accuracy, neither was it new. It was simply an arrangement of ordinary data to save time in calculating the date of delivery, as estimated by the size of the uterus, in cases in which the patient could not give a definite menstrual history.

Dr. R. D. PUREFOY read a paper entitled "Some Remarks on Tuberculous Salpingitis."—Sir A. V. MACAN said that there was a great difficulty as to the origin of primary tubercle of the tubes. If it did not ascend or descend they could only suppose that it filtered out from the blood. Sterility was one of the earliest effects of tubercle of the tubes, and he was not sure whether it would be much use to leave a small portion of the tube in such cases. He had at one time held the view that if they could not see their way to extirpate completely such affection of the tubes they had better leave them alone, but now he thought that they ought to remove as much as was possible and to trust to the patient's general strength to get rid of what was left behind.—Professor ALFRED SMITH, Mr. SHEILL, and others also took part in the discussion.

SECTION OF PATHOLOGY

Exhibition of Specimens.

A MEETING of this section was held on March 20th, Dr. JAMES LITTLE being in the chair.

Dr. R. TRAVERS SMITH exhibited a specimen showing Perforation of the Œsophagus. The patient was a girl, aged 18 years, who was admitted to a hospital complaining that for three days she had had a sore throat and felt very ill. The sore-throat was said to have begun after the swallowing of a small piece of rasher bone. Nothing could be found in the throat except that the anterior parts of the throat were red and swollen. There was a slight general tumefaction of the neck externally but no particular enlargement of the glands. Her temperature was 104° F. and her respirations were about 35 per minute. On further examination he found a small area of cutaneous emphysema over the lower margin of the ribs on the left side and came to the conclusion that the piece of bone had probably perforated her œsophagus. A number of staphylococci were found in the blood, the emphysema became more marked, and he was able to make out some left pleurisy and a slight pericardial friction rub. On the fourth day in hospital she was unconscious and moribund. At the necropsy the emphysema was well marked; a small amount of pus and fibro-purulent material was found in the left pleural cavity, and there was, perhaps, some air in it; there were also some fibro-purulent pericarditis and emphysema in the abdominal cavity all round the left kidney. In the œsophagus, just below the level of the cricoid cartilage, there was a double perforation, one hole being a little lower than the other. No distinct abscesses had formed. There was no sign of a bone to be found anywhere; it had probably become softened and made its way downwards and was possibly subsequently discharged.

Dr. G. PEACOCKE showed a specimen of Cirrhosis of the Liver from a woman, aged 46 years, who had always lived a temperate life. For 12 months she thought she had been getting stouter but did not complain of illness until a fortnight before admission to a hospital. When in the hospital she was suffering from extreme respiratory distress; her abdomen was enormously distended and tense and the abdominal wall was œdematous; the lungs, too, were œdematous. The apex beat of the heart was heard in the third space and a systolic murmur was heard over it. The urine was very scanty, high-coloured, and slightly albuminous. The distension was due to fluid which had come on with great suddenness. The abdomen was opened and drained, 14½ pints of fluid being measured, apart from a considerable amount which escaped. Drainage was continued for 48 hours, three to four pints being measured daily. She remained with slight elevation of temperature for a few days and then became duller, finally lapsing into coma for 48 hours, and then dying. The surface of the liver was nodular and extremely hard and a microscopic section showed very advanced cirrhosis. The case was interesting from the fact that it showed that the use of alcohol was not necessary to the condition.—Dr. WILLIAM R. DAWSON said that the contention that cirrhosis of the liver and alcoholism were not directly related was borne out by a converse observation. It had been pointed out by the late Dr. Conolly Norman and by Dr. F. W. Mott, of the London County Asylums, that cirrhosis was rare in asylum necropsies, although a large proportion of the cases admitted to pauper asylums were alcoholic.

Professor O'SULLIVAN exhibited a specimen showing a form of Aortitis associated with Sudden Death. Some years ago he had received the heart of a young soldier who had dropped dead on the march. He was apparently perfectly healthy. The appearance of the heart struck him as being very unusual and he observed that immediately above the commencement of the aorta, along the line of the valves, there was an abrupt rise in the surface level which continued for about an inch upwards into the vessel and then as abruptly descended again, forming a sort of table-land across the vessel a quarter of an inch or more higher than the rest of the surface. The left coronary artery was obstructed by the excrescence of the surface, which he took to be the cause of death. The specimen had gone astray but he was able to exhibit a similar specimen from a young man who had been found dead a few days before in a lavatory. The condition of his heart was almost identical with that of the other case. There was very little degeneration compared with an ordinary case of atheroma. The amount of overgrowth of the inner coat of the vessel, as compared with the amount of degeneration, was enormous. The orifice of the right coronary artery was practically closed; the opening of the left coronary artery was also reduced to small dimensions. A small depressed area, about an inch from the sinuses, was stained red and found to have undergone a different degeneration from atheroma. Under the microscope was seen a great rise in the inner coat, composed of a reduplication of the inner tissue, but in the middle coat the elastic tissue was cut and torn, and split by masses of cell infiltration which ran along the course of the vasa vasorum. The natural conclusion was that both cases were syphilitic although there was no direct evidence.

Dr. THOMAS G. MOORHEAD exhibited a specimen of "Surgical Kidney" taken from a woman, aged 42 years. Two days previously to admission to a hospital she had a sudden shivering fit, with pain in the abdomen and vomiting. He found distinct crepitus at the base of the left lung and rigidity of the abdominal wall, which yielded slowly to pressure. Her temperature, appearance, and respiration became typical of acute pneumonia, of which she developed further distinct symptoms later. There was some pus in the urine, and the patient suffered from frequency of micturition, from which he concluded she had also some cystitis. The dulness in the left lung gradually increased, until about two-thirds of the lower lobe had become consolidated. Her temperature ran up to 104° or 105° F., and so remained for a fortnight. Her strength rapidly diminished and she died. Bacterial examination of the pus in the urine gave staphylococcus aureus, and the sputum gave a pure culture of the same. The abdominal organs were all found to be healthy with the exception of the bladder and kidneys. The former showed acute cystitis and the left kidney was enormously large and studded with abscesses. The left ureter was extended and acutely inflamed. The pus from the abscesses gave a pure culture of staphylococcus aureus. The thoracic organs, with the exception of the lung, were normal. The base of the left lung, instead of showing

Wiley and Sons. London: Chapman and Hall, Limited. 1907. Pp. 367. Price 8*s.* 6*d.* net.—The authors of this text-book have evidently taken pains to confine so far as possible the treatment of the subject to that part of it which bears on medical science. They have been mindful also of the important developments of physical chemistry which are related to certain bio-chemical phenomena. Thus, we find sections on the nature of solutions, osmotic pressure, ionisation, colloidal solutions, and so forth. The experimental directions are admirably clear and the experiments are well chosen. The book closes with a capital though somewhat short chapter on alkaloids and drug principles. If there is any fault to be found at all it is the extremely concise way in which the complete subject is treated.

Schema des Rumpfes. (*Outline Diagrams for Clinical Records.*) By Privat-dozent Dr. W. HILDEBRANDT. Munich: J. F. Lehmann. Price 1 mark 20 pfennig.—This is a set of 21 diagrams each on a page measuring 5 by 8 inches and provided with a perforated line for easy tearing out. The design differs considerably from that of the clinical diagrams commonly used in England. No part of the patient's arms is shown, but the closed surface formed by the ribs is supposed to be divided in a vertical line near the vertebral column and flattened out so that the same diagram shows both the front and back of the thorax, with the ribs, sternum, clavicles, vertebral column, and scapulæ; the whole circuit of the pelvis is also shown in a similar fashion, attached to the thorax by the vertebral column. Inside the cover there is printed a scheme of conventional lines or hatching to represent various degrees of dulness on percussion, thoracic mobility, and other physical signs.

Valentin's Practical Chemistry. By W. R. HODGKINSON, Ph.D., F.R.S. Edin., Professor of Chemistry and Physics in the Ordnance College, Woolwich. Tenth edition. London: J. and A. Churchill. 1908. Pp. 476. Price 10*s.* net.—There are some novel features in this work, notably the admirable reproductions of photographs, or rather micro-photographs, of sections of metallic alloys, by Mr. A. H. Coote, B.Sc., and the simplicity of the directions given by the author for the carrying out of simple experiments with the metals and their salts. The plan of the work reminds us of the text-books published in the "eighties," before the days of argon, helion, radium, or of "ions." The reactions of salts bear, therefore, no construction in the light of modern theory. The book, in fact, deals essentially with practical matters, such as the preparation of gases, the reactions of acids, bases, salts, alkaloids, and volumetric analysis. The metals are grouped according to the classic fashion of the older text-books. The information and descriptions may be found in most books of the kind but we have no doubt that Professor Hodgkinson's book is designed to meet the particular requirements of his own pupils, by whom, no doubt, it is appreciated.

The Schoolmaster's Year-book and Directory, 1908. London: Swan Sonnenschein and Co., Limited. Pp. 590. Price 7*s.* 6*d.* net.—This is an invaluable work of reference for those connected with scholastic circles and is arranged in three parts: (1) General information; (2) alphabetical lists of secondary schoolmasters; and (3) list of secondary schools. The first part contains a summary of the past "educational year" and a review of the present scholastic situation. As everybody knows, the unrest in educational matters is not confined to primary schools, although in the secondary ones the question at issue concerns the teaching of ancient languages more than the teaching of the ancient faith. The Year-book is not yet able to record any improvement in the professional organisation of schoolmasters, indeed, one important judgment delivered in the year has given many of them a very scant security of tenure. Medical men can sympathise with a body of men whose profession does not give them protection to which they should reasonably be entitled.

Minor Maladies and their Treatment. By LEONARD WILLIAMS, M.D. Glasg., M.R.C.P. Lond., Physician to the French Hospital, &c. Second edition. London: Baillière, Tindall, and Cox. 1908. Pp. 404. Price 5*s.* net.—It is not very long since we gave a warm welcome to this book on its début and our recollection of its merits was such that the speedy appearance of a second edition has not surprised us. We remembered well that its author was no respecter of tradition *quâ* tradition but the re-reading of his explicit confession of therapeutical faith leaves us a little astonished at the boldness with which he attacks certain established doctrines. Many will agree with him that the "chill" theory of the causation of visceral affections can be no longer maintained; some will uphold his view that the dread of "draughts" is a bogey which has frightened the majority of the public to dwell habitually in the atmosphere of stuffy rooms; but how many will follow him when he bids us to cease from wearing wool or flannel next our skins, as not being absorbent of moisture, and to substitute loose woven linen, or cotton, or silk? Silk underclothing is luxurious raiment for the favoured few but we cannot doubt that a winter garment of woollen material brings more comfort to its wearer than does one of linen, whilst as regards summer wear, when palpable sweating is a serious factor, we can only say that in tropical experience flannels find more favour with most skins than do the cooler-looking "ducks." We have little else to cavil at. In an admirable chapter on indigestion all functional dyspepsias are divided into two provinces—sthenic and asthenic. The author himself speaks of the multiplication of terms in the description of this disorder and his purpose would surely be served by using the labels "acid" and "atonic" dyspepsia. We think that when he suggests the prescription of morphine in the treatment of indigestion in a lackadaisical woman of 30 years of age he should advise the concealment from her of the nature of the remedy. Two other little points we have noticed. His description of "Sir Andrew Clark's pill" on p. 111 implies the inclusion of both strychnine and nux vomica, and in another chapter his phrasing is open to the interpretation that he advocates the wearing of long hair by men who wish to escape baldness. We do not like the word "cardiopath." But these are trifles in the balance against the book's admirable qualities, its concise reasoning, tinged with judicious dogmatism helpful to the student, its therapeutical acumen, its balanced consideration of "diathetical" medicine, and above all its chapters on change of air and general health, which stamp its author as a rational climatologist and no faddist. What he has to say about spa treatment is illuminating and his advice to apply it in the treatment of constipated children, both as a curative and educative method, is only one instance of his resourceful habit of leaving the beaten track of practice in so-called "minor medicine."

Garcia the Centenarian and his Times. By M. STERLING MACKINLAY. London and Edinburgh: William Blackwood and Sons. 1908. Pp. 335. Price 15*s.*—Mr. Mackinlay, himself the son of a famous singer, known to most lovers of music as Antoinette Sterling, has written a book which is pleasant to read about a very remarkable personality. Garcia not only lived into his 102nd year but was a teacher of singing who ranks with Porpora and in the minds of the medical profession will ever be held in honour as the first to demonstrate the movements of the larynx to the eye by his invention of the laryngoscope in 1851. He embodied his observations in a paper read before the Royal Society in 1855. Not much notice was taken of the invention by the medical profession until Türck and Czermak, the former of whom had independently arrived at much the same conclusions as Garcia, took up the instrument from a diagnostic point of of the Conjunctiva and Microscopic Sections of Tissue from the same, and also a series of sections illustrating varieties of Nasal Neoplasms.—Dr. J. W. Browne showed specimens of Sarcoma of the Upper and of the Lower Jaw and a Portion of a Spinal Cord illustrating Intramedullary Hæmorrhage.—Mr. G. L. St. George showed an Acranial Fœtus.—Mr. J. A. Craig showed an Eye with Melanotic Sarcoma of the Choroid.—Dr. J. S. Darling showed specimens of Hæmato-salpinx, Colloid Cancer of the Peritoneum, and of a Peculiar Intestinal Tumour.—Professor Symmers showed the Lungs and Intestines from a Guinea-pig into which he had injected Indian ink into the stomach by a catheter while it was alive; when killed afterwards there was no sign of the material in the intestines but the lungs were very much pigmented. The experiment was indirectly confirmatory of Calmette's and von Behring's that even when supposed to be inhaled the tubercle bacilli reach the lung through the stomach.—Dr. A. Dempsey, Mr. J. O'Doherty, Mr. A. Fullerton, Mr. T. S. Kirk, and others also showed specimens of interest.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on March 26th, Mr. Thomas H. Bickerton, the President, being in the chair.—The proceedings took the form of a clinical evening.—Dr. H. R. Hurter showed a man, aged 35 years, suffering from Acrocyanosis Chronica Anæsthetica (cum gangræna), a condition allied to Raynaud's disease and erythromelalgia.—Dr. R. J. M. Buchanan showed a case of Argyria in a man.—Dr. A. Gordon Gullan showed a man, aged 56 years, suffering from Raynaud's Disease. He had a previous attack eight years ago lasting for 12 months. The symptoms included a typically red congested face and a swollen purple (asphyxial) condition of the fingers, the toes, the soles of the feet, and the ears. Dr. Gullan also showed a case of Myxœdema occurring in a woman, aged 55 years. The disease had developed gradually since the menopause became established at the age of 50 years. The symptoms included swollen face, malar flush, glazed dry skin, large swollen tongue, spade-like hands, subnormal temperature, and infrequent feeble pulse.—Dr. Nathan Raw showed (1) a case of Lymphadenoma occurring in a boy, aged 14 years, without enlargement of the spleen; and (2) a case of Extreme Bradycardia, the average pulse-rate being 26.—Dr. J. Owen and Mr. Douglas Crawford showed two cases of Deformity of the Hands—namely, (1) the "main en griffe" type resulting from cervical caries; and (2) the reverse picture (flexion of proximal, extension of second and flexion of terminal phalanges), in a case of pneumoconiosis.—Dr. N. Percy Marsh showed a child suffering from Meningitis in whom Calmette's reaction was positive; the cerebro-spinal fluid contained lymphocytes and did not reduce Fehling's solution. The treatment consisted in the use of Koch's tuberculin (T.R.) and was followed by recovery.—Dr. G. G. Stopford Taylor and Dr. R. W. MacKenna showed (1) a case of Tuberculous Ulcer treated by Bier's vacuum method; (2) a case of Lupus affecting the gums and hard palate; and (3) a series of Radiographs showing mercury lying in the tissues at varying intervals up to three weeks after intramuscular injections of grey oil.—Dr. A. Nimmo Walker showed a case of Glaucoma treated by Cyclotomy.—Mr. Hugh E. Jones showed a case of Chronic Suppurative Otitis Media with Granulations. The symptoms included headache, giddiness, pain, diplopia, and optic neuritis. A watch was heard on pressure only, the bone conduction being exaggerated. The complete post-aural operation was performed and was followed by the disappearance of all pathological symptoms and return of hearing.—Dr. John Hay showed two cases of General Paralysis of the Insane occurring in women, aged respectively 39 and 48 years, neither of whom had a history of syphilis.—Other cases were shown by Dr. W. B. Warrington, Dr. C. J. Macalister, Mr. R. W. Murray, Mr. R. C. Dun, Dr. Leslie Roberts, Dr. F. H. Barendt, and the President.—Mr. G. G. Hamilton gave a demonstration of Lumière's Colour Photography as applied to fresh pathological specimens. Illustrations were provided by 70 lantern slides, including human and comparative pathology.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 3rd, Dr. W. Langdon Brown, the President, being in the chair.—Mr. Elmore W. Brewerton read a paper on Injuries to the Eye with special reference to Sympathetic Ophthalmitis. He said that the commonest injury without penetration was caused by a blunt instrument such as a tennis ball, which caused immediate loss of sight and hyphæmia. The hyphæma usually cleared up in about a week; but too good a prognosis ought not to be given as traumatic cataract might result and the lens might be dislocated into the anterior chamber. Hæmorrhage into the vitreous was another common cause of temporary loss of sight but the patient usually recovered. Any penetrating wound might produce sympathetic ophthalmitis which might be defined as a plastic inflammation of the uveal tract subsequent to a plastic uveitis in the other eye due to injury. The modern theory of the pathology of sympathetic ophthalmitis was that it was due to the infection of a non-pyogenic organism, not yet isolated, which could not live in the presence of other pyogenic organisms. Many cases were caused by the iris getting entangled in the wound after cataract extraction. The rapid appearance of suppuration in an eye after an injury did not set up sympathetic ophthalmitis. The earliest sign of sympathetic ophthalmitis was the presence of hippus in the sympathising eye and one of the earliest symptoms was an accommodating asthenopia followed by lacrymation and pain which were characterised by marked exacerbations. As regards prophylaxis it was an axiom never to advise an intraocular operation unless it was absolutely necessary. As regards treatment, all injured eyes with no perception of light should be removed, and if a foreign body in the globe could not be extracted the eye should be removed. In doubtful cases the eye could be left in for 10 or 11 days without danger as the organism took about two weeks before it could develop in sufficient power to attack the other eye. If the eye was not quiet three weeks after the injury it should be removed. For the treatment of the sympathising eye mercury should be used till it caused mild salivation. The eye should be fomented and covered up and atropine used to keep the pupil dilated. For the pain dionin should be given and morphine if necessary.—Dr. A. L. Marshall related a case of Rupture of the Aortic Valve. A year ago a man, aged 42 years, who for six years had a soft mitral bruit, fell on the ground while running to catch an omnibus. He experienced no inconvenience whatever but complained of a loud noise in his chest. On examination, the apex beat was found in the fifth interspace inside the nipple line, the impulse was good and not heaving, and a loud diastolic bruit was heard all over the chest wall. The pulse was water-hammer in character but regular and full. The patient gradually got worse, but after four months' rest was able to resume his work which was very harassing. He had a troublesome cough which persisted in spite of all treatment and he could not sleep. Seven months after the accident the apex beat was in the sixth interspace, one inch outside the nipple line, and the impulse was diffuse. The pulse was soft and extremely easily compressible. On raising the arm upwards and outwards the radial pulse ceased. The aortic bruit extended up into the carotids and down to the femorals. He became rapidly worse and there was a large hæmorrhagic infarct of the left lung followed by pain in the chest and extreme shortness of breath and he died nine months after the accident.—Dr. Alexander Morison said that many reported cases of rupture of the aortic valve had been shown to be cases of compensated heart disease which had given way under a severe strain.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 1st, Dr. L. W. Marshall, the President, being in the chair.—Dr. F. H. Jacob and Dr. J. H. Thompson showed a youth, aged 18 years, who had been the subject of Acute Pneumonic Phthisis involving the whole of one lung 15 months before. Complete recovery had taken place, although the febrile temperature persisted for three months and the case at first appeared too hopeless to warrant admission to a sanatorium.—Dr. Jacob also showed an infant, aged 16 months, the subject of Multiple Tuberculous Gummata, the sequelæ of measles a year before.—Dr. M. Parry-Jones (Derby) read a paper on Diachylon Poisoning. The first case described by him was that of a woman, aged 34 years, admitted to hospital as doubtful enteric fever, with a three weeks' history of headache and diarrhœa. The temperature dropped from normal to subnormal and the pulse from 80 to 60. Weakness of leg and wrist muscles without wasting developed into dysphagia and coma but there was no optic neuritis. Alcoholic disease of the liver no doubt contributed to the fatal issue. A second case, in a woman, aged 24 years, proved fatal a few hours after her admission in a helpless semi-comatose condition. A third case, after running a most critical course, recovered in three or four months' time, with loss of memory and partial aphasia. These might in part be attributed to an exploration of the temporo-sphenoidal lobe, undertaken at one stage in be placed within the boot. The cushion is a combination of leather, rubber, and cork, the three being in layers which are sewn together in the front and left loose at the sides and back, the line of suture in the front forming a hinge. The leather covering is on the top, then comes a layer of indiarubber, and then a layer of cork, and by the addition of cork wedges varying in thickness, which can be held in position by an ordinary elastic band, the height of the cushion can be raised to suit the convenience of the wearer. The apparatus is placed in the heel of the boot and is secured there by a sharp stud on its under surface. The inventor claims for the Talmore heel-cushion that it is a great improvement on anything hitherto invented for increasing the height of the wearer; but we are not much concerned in a medical paper with its merits from this æsthetic point of view. If a man or a woman decides to increase his or her height by the use of pads beneath the heels we can conceive that the Talmore heel-cushion would be a good contrivance for the purpose, but our remarks are applied to its employment for more serious purposes. The indiarubber layer is constructed of good soft material and is moulded to take the imprint of the heel of the wearer, being thinned towards the centre of the under surface so that upon pressure the heel sinks into a depression and the weight of the body remains supported in the normal way instead of being thrown forward on to the toes in walking. The foot will slide or tilt forward in such a way as to throw some of the weight of the body on to the toes if the cushion is adjusted at a disproportionate height, but the proper elevation must be determined by trial, preferably in the presence of the surgeon. In cases of slight inequality of length of the limb and certain forms of club-foot the Talmore heel-cushion will be found a convenient and useful little apparatus. It has been commended to our notice by a well-known surgeon and is already in satisfactory use by two patients. The price of the heel-cushions is moderate and they can be obtained from the general agents for their sale, Messrs. E. Penton and Son, 1 to 11, Mortimer-street, London, W., and will shortly be procurable through the usual surgical instrument manufacturers. Mr. Bascombe will answer any questions concerning the use of the apparatus.

BRITISH MEDICAL BENEVOLENT FUND.

AT the March meeting of the committee 23 cases were considered and grants amounting to £216 were made to 20 of the applicants, one case being passed over and two postponed for further inquiries.

Mr. E. Parker Young was re-elected chairman of the committee for the ensuing year.

Appended is an abstract of the cases relieved :—

Wife, aged 45 years, of L.F.P.S. Glasg. who is permanently incapacitated. Applicant has tried to obtain post as housekeeper or companion and neither she nor her husband has any means. Three children, of whom two are partially dependent. Voted £16.

Daughter, aged 51 years, of late M.R.C.S. For the last few years has been obliged to nurse her mother, an Epsom annuitant, recently deceased. Is endeavouring to obtain pupils and meanwhile is dependent on two sisters who both earn a very precarious living. Voted £10.

Daughter, aged 43 years, of late M.R.C.S., L.R.C.P. Only income a few shillings a week and has recently undergone a severe operation. Voted £5.

Widow, aged 49 years, of M.R.C.S. Eng., L.R.C.P. Edin. Husband's means were exhausted by an illness lasting several years, during which applicant nursed him and endeavoured to maintain the family by keeping a boarding-house which has now had to be given up owing to her ill-health. Five children, of whom two are able to help and two are dependent. Relieved five times, £72. Voted £10.

Daughter, aged 58 years, of M.R.C.S., L.S.A. No income; earns a few shillings a week by needlework and occasionally receives slight help from friends. Relieved once, £18. Voted £12.

Daughter, aged 56 years, of late M.R.C.S., L.S.A. Was provided for at father's death but lost everything through the dishonesty of a friend. Only income £10 a year from a charity. Relieved four times, £56. Voted £12.

Widow, aged 68 years, of L.S.A. Practically unprovided for at husband's death and endeavours to support herself by letting lodgings. Five children, but only able to give very slight help. Relieved six times, £70. Voted £10.

Daughter, aged 59 years, of late M.R.C.S. Until recently had a daily teaching engagement, but was obliged to give it up to nurse an invalid sister, lately deceased. No income; slight irregular help from friends. Relieved once, £18. Voted £12.

Widow, aged 50 years, of L.R.C.P., L.R.C.S. Edin. Quite unprovided for at husband's death. Six children who help as far as possible. Relieved twice, £20. Voted £10.

Widow, aged 59 years, of M.R.C.S. No income. Lets lodgings. Six children, of whom two are able to give slight help and three are dependent. Relieved twice, £24. Voted £10.

Daughter, aged 64 years, of late M.R.C.S. No income and health so indifferent that regular employment is impossible. Tries to let lodgings but it is only possible for a few weeks in the summer. Small earnings from needlework. Relieved four times £48. Voted £12.

Widow, aged 67 years, of M.R.C.S., L.S.A. Was left entirely unprovided for and for 20 years held a situation as cook in a boarding house. Health now very indifferent. No children. Relieved twice, £24. Voted £14.

Daughter, aged 62 years, of late L.R.C.P. Edin., L.S.A. Used to be employed as a dressmaker, but lost her situation owing to changes in the firm and is now unable to obtain another engagement. Dependent on a friend who allows a few shillings a week. Relieved three times, £30. Voted £10.

Daughter, aged 52 years, of late M.R.C.S., L.S.A. Applicant's mental condition is such that for some years past she has been dependent on three half-sisters who all have to earn their living, and at present she is confined to an institution. Relieved four times, £44. Voted £12.

Daughter, aged 48 years, of late M.R.C.S., L.S.A. Is an epileptic and unable to earn a living. Slight help from relatives and receives £10 a year from the Hospital for the Paralysed and Epileptic. Relieved once, £12. Voted £12.

Widow, aged 39 years, of L.R.C.P., L.R.C.S. Edin. Has trained as a maternity nurse and requires a little help to enable her to present herself for examination at the Central Midwives Board. Two children, aged 11 and nine, both at institutions. Relieved once, £5. Voted £5.

Widow, aged 63 years, of M.D., C.M. Glasg. Receives £14 a year from the Ladies' Working Guild and is given a little help by her son who is a signalman. Practically incapacitated by chronic rheumatism. Relieved eight times, £94. Voted £10.

Daughter, aged 62 years, of late M.R.C.S., L.S.A. No income. Health too bad to admit of regular employment and is allowed a few shillings a week by a sister. Relieved ten times, £113. Voted £12.

Widow, aged 50 years, of L.R.C.P. Edin., L.S.A. No income. Health indifferent. Is at present engaged as a caretaker without salary. No children. Relieved four times, £34. Voted £12.

Widow, aged 47 years, of M.R.C.S. No income. Earns a little by needlework. Two children, one being dependent and the other unable to help. Relieved six times, £59. Voted £12.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 10th, 1830.

COLLEGE OF PHYSICIANS.

April 5th, 1830.

EFFICACY OF THE GUACO PLANT IN VENOMOUS BITES.

A PAPER by Sir ROBERT KER PORTER[1] on the virtues of the *guaco*, a plant from Caraccas, South America, was this evening read by the Registrar (Dr. Hawkins); it referred chiefly to its remedial qualities in cases of bites received from venomous serpents, the black scorpion, and in hydrophobia. It was stated in the paper, that a native physician had communicated to Sir Robert the result of his experience in its employment, and that its virtues had been known from time immemorial amongst that portion of the black population termed *empiricos*, from their being noted for their exemption from the dangerous effects of such bites. One of these empiricos showed this native physician his confidence in the power of his remedy, by handling one of the most dangerous species of serpents which he had brought with him in a calabash, without apparent precaution of any kind; although, on examination, the animal was found capable of employing its fangs with full effect, the man escaped without injury. On being rewarded for the exhibition, the empirico stated that he derived his preservative from the leaves and juice of the guaco. He subsequently "inoculated" the physician in different parts of the body, by inserting bruised leaves of the plant in the incisions he had made, and giving him some of the juice to swallow. After this preparation, it was found that the serpent had no power, or, at any rate, no inclination to injure him. His servants repeated the same experiment with impunity. The paper went on to state, that the dangerous effects of the bite of any reptile were, without fail, prevented by the use of this remedy, but particularly if swallowed some time previously. The virtues of the guaco were stated to have first become known, by its being observed that a particular species of "*falco*," which preyed on serpents, attacked them successfully after eating some of the leaves, the effects of which were considered as not confined to the cure of venomous bites, but to extend to cases of severe rheumatism of many years standing, and other chronic complaints. Specimens of the plant and juice were on the table of the Hall.

---

[1] Sir Robert Ker Porter, known as a painter and traveller, was also British Consul at Caracas (Venezuela) from 1826-1841.

The book ought to prove most valuable to teachers and to medical men.

Mr. Urwick's work is an attempt to set forth in simple, untechnical language some results obtained from a study of the growth of the mind as an organic process and to establish a clear and definite connexion between those processes of learning which the mind possesses and the methods by which it should be taught and trained. The school is intended as a short cut to prepare the pupil to take his place in the society to which he belongs but it does not undertake to prepare for life under any ideal conditions but for life under the actual conditions, hence there can be no ideally best curriculum or school. Education should prepare for the daily work or calling as well as for the sphere of social life. Some of the most interesting chapters are those on learning and the growth of ideas, the growth of ideas in imaginative processes, and reasoning as mind's higher processes. The work is one replete with interest and should be read by every teacher because of its suggestiveness.

Handbook of Meat Inspection. By Dr. ROBERT OSTERTAG, Professor in the Veterinary High School of Berlin. Authorised translation by EARLEY VERNON WILCOX, M.A., Ph.D., Veterinary Editor, Experiment Station Record. With an introduction by JOHN R. MOHLER, A.M., V.M.D., Chief of Pathological Division, United States Bureau of Animal Industry. Third edition, with coloured plate and 260 illustrations. Royal 8vo. London: Baillière, Tindall, and Cox. 1907. Pp. 884. Price 31*s.* 6*d.* net.

AS an authority on this subject Dr. Robert Ostertag holds the first rank and has been quoted on all sides and in almost every work dealing with meat-supply and with slaughter-houses. Earlier editions of his works have been noticed in these columns and we are now pleased to welcome an authorised and carefully produced translation. The author was consulted at different stages of the translation and has made certain alterations, so that the information given should coincide with the actual state of the law on the inspection of meat in Germany. Moreover, Mr. John B. Mohler contributes a very useful chapter describing similar legislation in the United States of America. We are thus able to see that while in Great Britain a large amount of American meat has been consumed, no action whatever was taken to protect the British public—it was Italy that took the initiative. The example of Italy being closely followed in 1881 by Austria, Germany, and France, the United States, to save their trade with Europe, began to enact laws for the inspection at least of such meat as was to be exported to those countries. Then follows the history of the gradual improvement of these laws and of the methods for the recruiting of the staff of inspectors whose duty it is to carry out the laws. It is obvious, however, from the figures given that though the number of inspectors of meat appointed by the Federal Government has of late been greatly increased the staff is still quite inadequate.

The greater part of the work deals in detail and with the aid of numerous illustrations with the various diseases found in animals used for food, including fish. All that bacteriology and the study of the life and habits of parasites can contribute to the great practical purpose of preserving the public from unwholesome food is treated in full detail. This, of course, includes a special study on the important question of tuberculosis and the difficult problem of deciding how far the disease is so completely localised as to allow some of the meat to be sold as food. The gravity of this question may be judged from the fact that the author says: "It must be assumed that tuberculosis may be transmitted to man by the consumption of tuberculous organs." He states that the bacillus in man and in animals is the same and that the disease has been transmitted experimentally from man to cattle, hogs, and sheep. Also, cases are known where men have contracted through the skin tuberculosis from domesticated animals, notably in milking cows with tuberculous udders. Where the tuberculosis is undoubtedly localised the meat is considered harmless. But Dr. Ostertag considers as "probably possessed of a harmful character to a high degree" all cases of generalisation with tuberculous changes in the "musculature, bones, joints, and lymphatic glands of the muscles, and also all cases of fresh generalisation with tumefaction of the spleen and all the lymphatic glands."

There are also many pages devoted to processes of preservation of food and to the detection and prevention of adulteration. Altogether we think that this is a volume that will prove of great practical service to those who are engaged in the endeavour to prevent any but wholesome food being placed on the market.

Medicine in the British Isles. By NORMAN MOORE, M.D. Cantab. Being the Fitz Patrick Lectures for 1905–1906. Oxford: At the Clarendon Press. 1908. Pp. 202. Price 10*s.* 6*d.*

THESE admirable lectures, an abstract of which appeared in our columns at the time of their delivery, will be read with delight by every medical man who cares to know anything of the history of his profession. Dr. Moore is well known as one of the most learned members of the Royal College of Physicians of London and has only recently passed on the torch received from his accomplished predecessor, Dr. J. F. Payne, to the no less careful keeping of Dr. L. G. Guthrie. The founder of the lectures would indeed rejoice could he know by what skilled minds his bequest has been carried out.

Of the four lectures the first deals with medical study in London during the Middle Ages and is mainly devoted to the life and writings of John Mirfield who flourished in the fourteenth century and who was a canon regular and a medical man attached to the Priory of St. Bartholomew, although he was not apparently definitely attached to the hospital. He was a widely read and "a laborious and high-minded man, anxious to do all in his power for his patients and to instruct others how to relieve suffering." The second lecture deals with the education of physicians in London during the seventeenth century and the chief point which strikes the reader is that although anatomy, physiology, and other studies germane to medicine had advanced enormously since the Middle Ages, yet treatment remained much where it did. Dr. Moore gives an amusing account of one Simon Ludford who was ploughed by the College of Physicians and who afterwards tried to obtain a licence to practise from both Oxford and Cambridge without success. Whatever Ludford's medical attainments were his Latin verses were appalling. The copy of Sapphics which Dr. Moore quotes would certainly have been "torn over" had their author been at Eton. The third and fourth lectures treat of the history of the study of medicine in the British Isles and are worthy of the attention of every medical man. Especially interesting as being information unknown to most readers are the sections dealing with the study of medicine in Ireland. We have derived much pleasure as well as profit from reading these lectures and cordially recommend our professional brethren to read them also.

LIBRARY TABLE.

Organic Chemistry, including Certain Portions of Physical Chemistry, for Medical, Pharmaceutical, and Biological Students. By H. D. HASKINS, A.B., M.D., and J. J. R. MACLEOD, M.B. Aberd., D.P.H. Cantab. New York: John habitation, and if it appears to the sanitary authority that this condition is not complied with the landlord may be called upon to carry out the necessary repairs and in default of his doing so they may be executed at his expense by the authority. All this is excellent but both these clauses will be quite inoperative unless the official—again the medical officer of health—who is, in the first instance, to tell the sanitary authority that a particular house is not in "all respects reasonably fit for human habitation," is in an absolutely independent position and free from the least suspicion of partiality or prejudice.

There is reason to believe that an effort will be made to get inserted in the Bill a clause which in the future will prevent the appointment of medical officers of health for a limited period but which will enable a sanitary authority to remove them from office after reasonable notice and with the sanction of the county council or the Local Government Board. If the supporters of the Bill are genuinely anxious that its provisions shall be enforced and that they shall not remain a dead letter, as so many other public health enactments have remained, they will admit the principle of this additional clause. We are fully aware that there are difficulties surrounding the question that do not appear on the surface. There is, for example, the interference with the control of the local electing body, which it must not be forgotten, however, pays only one-half of the salary of the medical officer of health but which claims to have complete control over him. As the Imperial funds contribute an equal portion of his salary there can be no injustice in the State having a voice in the conditions of his appointment. Then there are the so-called difficulties connected with compensation in case it should be found necessary to call for the retirement of a medical officer of health in consequence of the re-arrangement of districts into one or more combinations. Similar difficulties were successfully overcome in connexion with Poor-law appointments by the permanent officials of the middle of the last century, and we can hardly believe that their successors are less capable or less skilful in this direction. They have an opportunity for displaying their skill and their capabilities which ought not to be lost and we have every confidence that if they use it aright they will have the cordial support of all those who have the well-being of the people at heart.

◆

Unqualified Practice and Secret Remedies.

THE question of the practice of the medical art by unqualified persons, together with the unrestricted sale of "secret" remedies, is becoming a very serious matter as regards the health of the people. Not that these two forms of "commercial activity" are anything new, for quacks of all kinds flourished in the Middle Ages, although perhaps they attained their zenith so far as impudence went in the later years of the eighteenth century. But we think that at the present time they are far more mischievous than of yore and that for many reasons. First, their numbers have increased. Secondly, owing to the spread of education nearly everyone can read, and does read, the cheap press and the cheap monthly magazines. Thirdly, owing to competition the owners and editors of the daily press and of the popular magazines exercise a most indifferent control over the advertisements which appear in their columns. One honourable exception recently existed, but we regret to say is now defunct, and that was our late contemporary the *Tribune* which did do its best to keep out offensive and deceitful advertisements. But the reader who takes up nearly any daily journal will be almost certain to see flaming advertisements of secret remedies which promise far more than is possible of performance. That of Bile Beans for instance, still appears in the public press, and it was of this business, it will be remembered, that Lord ARDWALL, one of HIS MAJESTY'S judges in Scotland, said it "was one founded entirely upon fraud, impudence, and advertisement."[1] In the *Daily Chronicle* of March 30th is a whole column advertisement *headed "Special to the Daily Chronicle."* In *this advertisement it is stated* that an absolute cure for cancer has been discovered, the inventor being a certain Professor STROOP. We have selected these two advertisements at random as they appeared quite recently but there are plenty of others just as mischievous. And not in these islands alone is the evil widespread. In Australia a Royal Commission has recently been held on the matter with the result that a report embodying most stringent recommendations was issued in the later months of last year.

Other countries of Europe are feeling the evil also and we have before us the main provisions of a Bill which has been drafted for consideration by the German Parliament and which has been printed in the journal *Soziale Medizin und Hygiene*. Many of the provisions are very similar to the recommendations of the Australian Royal Commission, the most important of which were given in the letter from our Australian correspondent which appeared in our issue of Oct. 5th, 1907, p. 995. Legislation to prevent or to put an end to quackery has been tried in many countries and has as a rule proved unsuccessful. For no legislation, unless it be of a Draconic nature, is successful unless the population of the country in which it runs is in sympathy with it, and it must be confessed that the population of most countries revels in quack medicines of all kinds. There are, however, certain legislative enactments which would prove of great use, and they are those which have for their object first the purifying of advertisements and, secondly, the removal of secrecy. The following, taken from the draft German Bill, will show the kind of legislation to which we refer:—

Any person who shall cause to be circulated any advertisement or puff dealing with the prevention, alleviation, or cure of any human or animal disease, pain, or injury, and containing wilful mis-statements such as are calculated to give rise to misconceptions as to the value or efficacy of the remedy, article, or method advertised, shall be punishable by imprisonment for a term of not exceeding one year and shall be liable to a fine not exceeding £150; or shall be liable to one of these penalties. The same holds good when such persons shall wilfully make mis-statements having reference to the manufacturer or originator of the remedy, article, or method in question, or having reference to any person responsible for such advertisements, or who shall make mis-statements regarding the "professional" results of one or other of these persons.

The following persons shall be guilty of a misdemeanour and shall be liable on conviction to imprisonment for a term view. From a musical point of view Garcia's period covers all the important musicians and singers of the nineteenth century and many of the latter were his pupils. When he was born Haydn had still four years to live, so that Garcia might well have talked to a man who had been the contemporary of Handel and Bach. Beethoven was in his thirty-seventh year. Mr. Mackinlay's pages will revive memories of the great days of the Italian opera when Garcia's gifted sisters Malibran and Pauline Garcia (still living) charmed all ears, while the well-known names of Jenny Lind, Mario, Lablache, Miss Dolby, and others constantly occur. All lovers of music should read the book and especially medical men. We think, by the way, that Mr. Mackinlay's remark on page 109 that Vive Verdi is synonymous with Vive Victor Emanuel is calculated to lead those who are not conversant with the circumstances astray, for the whole point of the cry—which, by the way, was Viva Verdi—lies in the letters rdi = re d'Italia, and not alone in the ve = Victor Emanuel.

---

[1] THE LANCET, Sept. 16th, 1905, p. 861.

JOURNALS AND MAGAZINES.

The Medical Chronicle.—The March number of this magazine is the third and last Dreschfeld Memorial Number. Dr. F. H. Edgeworth and Dr. I. Walker Hall record a case of phosphorus poisoning and some observations on the amino-acids excreted in the urine. Dr. Charles Powell White writes on cholesterol, fluid crystals, and myelin forms, and Dr. W. Mair on gas-containing cysts or air-bladder tumours met with in human pathology. Professor J. Lorrain Smith discusses a case of hæmolymph gland, and Professor J. Dixon Mann contributes a note on colourless fæces without jaundice. Dr. A. Hill Griffith records a case of (?) tubercular intra-ocular growth, and Dr. E. N. Cunliffe one of Still's disease, in which there was reason to consider the condition to be tuberculous. Dr. E. M. Brockbank writes on blood-plates, and Professor Sheridan Delépine summarises his observations on the dirt and pathogenic germs contained in the milk supplied to the town of Manchester during the ten years 1897 to 1906 inclusive.

The Birmingham Medical Review.—In an address delivered before the Midland Medical Society which appears in the February issue of this journal Professor R. Saundby discusses the question of amendment of the Medical Act in respect to its penal clauses and emphasises the danger of throwing the existing conditions of medical practice into the melting pot of Parliamentary discussion. Dr. A. C. T. Woodward writes on the treatment of acute inflammations by Bier's method of passive hyperæmia. Three cases of acute cellulitis are recorded and the author notes that he has had good results in cases of delayed union in fractures and in others of stiff joints and adhesions in tendon sheaths.

St. Mary's Hospital Gazette.—A paper read by Dr. J. Bart Ross before the Hospital Medical Society and published in the March number of this gazette, entitled "Some Glimpses of the Study of Medicine by Englishmen in the Past," gives some interesting excerpts from mediæval medical works. The old physicians appear to have made up for lack of scientific knowledge by a good deal of worldly shrewdness, verging at times upon imposture. The advice, however, given by one, John of Arderne, as to the relations between members of the medical profession can hardly be improved upon in the most recent text-book of ethics.

St. Bartholomew's Hospital Journal.—In the March number Mr. Frank A. Rose records some cases in which an erroneous diagnosis of adenoids was made, and Mr. B. V. Favell gives notes of a case of lepto-meningitis following fracture of the base of the skull. A paper by Dr. C. Addison contains a discussion of social problems connected with population, housing, and so forth, and ends apparently with an aspiration for further State interference in this domain.

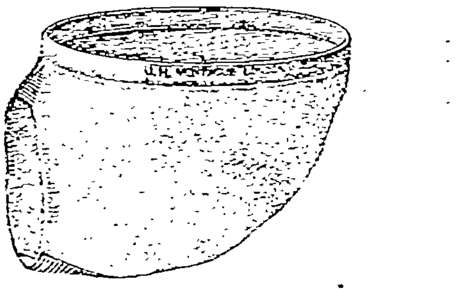
The Middlesex Hospital Journal.—In the March issue is published a paper read before the Hospital Medical Society by Mr. H. F. Woods on the subject of hypnotism. An account of the development of this branch is given and suggestions are made as to the more frequent employment of this method in producing anæsthesia in minor operations, such as tooth extraction, and in midwifery practice.

Guy's Hospital Gazette.—In the issue of March 7th is published a clinical lecture by Mr. Charters J. Symonds on obstructed hernia, a condition which is to be regarded as in reality one of strangulation. A paper read by Mr. Lee Atkinson before the Pupils' Physical Society sets forth a new theory of cancer, based on the view that there is normally present in the blood a principle which inhibits growth and which is usually in equilibrium with the force which makes for growth in the tissues. In cancer this balance is somehow upset. There is much of interest in the paper, even if the hypothesis itself seems scarcely likely to be fruitful. In the following number (March 21st) is contained a clinical lecture by Dr. W. Hale White on jaundice due to portal pyæmia, with some useful comments on the diagnosis of cases of jaundice in general.

New Inventions.

AN ARTIFICIAL PELVIC FLOOR FOR DEMONSTRATION PURPOSES.

EVERYONE who teaches midwifery to nurses must be aware of the difficulty of making them really understand what the pelvic floor is and does. The article illustrated was designed with a view to lessening this difficulty. It consists of a ring of whalebone which fits into the pelvis at the level which is usually described as the plane of the cavity of the pelvis. A hammock-like arrangement of batiste is suspended from the ring and opens forward. At the two extremities of the opening pieces of elastic are inserted, thus allowing of considerable distension of the artificial vulval opening. This improvement was suggested by Dr. R. J. Collie. When placed in the pelvis and folded up the model gives the nurse a rough idea of the pelvic floor in its ordinary condition. When a fœtal head is passed through a pupil cannot but appreciate the action of the pelvic floor in rotating the head, and the distension of the vulva by the various diameters of the head is realistically demonstrated. These pelvic floors are used in the London County Council lectures to midwives.



The model is constructed by Mr. J. H. Montague, 69, New Bond-street, London, W., of the best material and can be obtained for 4*s.* 6*d.* C. J. NEPEAN LONGRIDGE.

THE TALMORE ADJUSTABLE HEEL-CUSHION.

WE have received from the designer, Mr. R. E. Bascombe, Alvington House, Bury St. Edmunds, specimens of a small invention which will be found useful in cases of slight shortening of a limb. The title, in fact, reveals the inventor's purpose of making an artificial addition to the heel. This is done by means of an ingeniously contrived cushion to

Annotations.

"Ne quid nimis."

RICHARDSON *v.* FREMLIN.

FORTUNATELY for the good reputation of medicine cases involving disputes over fees do not often come before public notice, and when they do it is almost invariably a question of a fair professional fee being disputed by the public, members of which too often consider that they have a right to value professional services at their own estimate. Unluckily, cases do occasionally arise in which the patient has been overcharged and a regrettable example of this has recently attracted much public attention. In the case of Richardson *v.* Fremlin, reported in the *Times* (on March 31st and two following days), the plaintiff, a dentist, claimed the sum of £570 3*s.*, an amount alleged to be the sum agreed upon for professional services rendered to the defendant's wife. This large amount was made up of the sum of £389 11*s.* for 185½ half-hours' work for surgical and operative work, in addition to the sum of £180 12*s.* for mechanical work. The actual work done consisted of the restoration of the teeth of the upper jaw by means of a removeable bar which the plaintiff claimed was a work of great and exceptional difficulty and could be done by no other dentist in England. It would appear from the evidence of Mr. Richardson that he explained to Mr. Fremlin his charges and the character of the work which he intended to do. As far as can be gathered from the report, the "bridge" was attached to five roots, and on the preparation of these and the denture the plaintiff alleged that he had spent 185½ half-hours at 4 guineas an hour. The expert evidence for the defence showed that the work done by the plaintiff was such as could be done by any fairly competent practitioner and that a reasonable charge for the work would have been something between 75 and 100 guineas, and it was clearly brought out that the plaintiff had charged for preparing one tooth for the bar the sum of £65 12*s.* 6*d.* In summing up Mr. Justice Grantham stated that the question which the jury had to decide was whether there was a contract, and in his opinion there was some evidence of a contract. Assuming the contract to be for 2 guineas for every half hour, the question was whether that meant every half hour that the plaintiff could succeed in keeping the patient in the chair, or every half hour really taken up with work, and it was also a question for the jury whether all the half hours were properly charged. The plaintiff had suggested that the time which he had had to devote to the patient had ruined his practice, but reference to his day book showed that this was not the case, and that on many occasions he had no other patients, and that he could, if necessary, have devoted twice the time to the patient. In reviewing the case we cannot help feeling that an excessive time was taken in preparing the work. But, granting that the time given by the plaintiff was not one minute less than that which was necessary for the proper treatment of the case, he would, we think, have been acting in a more satisfactory manner if he had given to Mr. Fremlin some more definite idea of the very large amount that would have to be paid for the operation. It seems also to be uncontradicted that in this case the plaintiff led his patient to believe that he was the only man in the whole of England capable of doing the class of work that was being done. Tactics of this sort undermine the confidence of the public in the professional man, and we were surprised to find a gentleman who holds a position on the representative board of the British Dental Association giving evidence in support of the claims of the plaintiff. The jury returned a verdict for the plaintiff for £178 5*s.* in addition to £100 paid into court, and we do not think that many of Mr. Richardson's professional brethren will feel much sympathy with him in recovering some £300 less than his claim. We mention this because Mr. Richardson seemed to think that his action was in some way taken for the vindication of professional rights.

THE REMOVAL OF SUPERFLUOUS HAIRS.

THE distribution of hair appears to many to be an exception to the general law of wise beneficence which characterises the arrangements in this world, for while many of us have to deplore the too early departure of the hair from the scalp others lament even more bitterly the appearance of hairs on the lips and chin. There have, it is true, been "bearded" women who have worn with pride these hirsute ornaments, rarely vouchsafed in so great a degree to members of their sex, and in some countries, such as Spain, a little moustache is considered to enhance a woman's charms. In this country as a rule, however, any visible indications of a beard or a moustache are not welcomed, and the fervency of the wish to be deprived of them is proved by the numerous advertisements which exist with regard to their removal; in fact, there are as many preparations for removing unneeded hairs as there are for re-covering with hair scalps that are prematurely bald. How can superfluous hairs be removed? The simplest answer to this question is to suggest an application which may in some cases do away with the need for the removal of the hairs. Dark hairs are much more conspicuous than fair hairs and if the hairs can be made lighter in colour they will be much less visible. There are many substances which will bleach the hair but the best is certainly peroxide of hydrogen, and for slight cases of hairiness it is quite sufficient. The lotion has to be used at frequent intervals, for it has little, if any, permanent effect, though some have claimed that under its use the hairs grow less freely. In Eastern countries depilatories of various kinds are much used and they nearly all consist of pastes or lotions containing, amongst other ingredients, a sulphide of an alkali or of an alkaline earth; those most commonly used are the sulphides of calcium and of barium. The action of these sulphides is due to the fact that the keratin of the hair is a little more easily acted on by the sulphides than the keratin of the skin. They do, however, dissolve the keratin of the skin, and if they are employed in too strong a form, or if they are left too long in contact with the skin, the part is made very sore and red, and if the process is frequently repeated the growth of hair seems to be stimulated and the last state may easily be worse than the first. The sulphide must be employed well diluted with some innocuous substance such as oxide of zinc, and when the paste is removed it should not leave behind it a redness of the skin lasting for more than a few minutes. If employed with care the sulphides form useful depilatories but the effect is merely temporary and the application needs to be renewed about every week or two. For epilating the scalp in cases of ringworm and favus the x rays have within recent years been much employed, and when used by those well skilled in their employment they have generally given satisfaction. The hair returns usually in a few weeks after the application and grows freely. Attempts have been made to employ x rays for the permanent removal of hairs and there can be no doubt that the rays do possess the power of destroying the hair follicles, as has unfortunately been shown in a few cases where the rays have been used for the treatment of tinea and other conditions. Occasionally the x rays have been used for the destruction of the hair follicles of the chin but the risks are very great and we have known of cases in which ulcers, scars, and marked telangiectases have replaced the hirsuties and hence made the appearance much more

THE LANCET.

LONDON: SATURDAY, APRIL 11, 1908.

The Housing Bill.

As stated in our Parliamentary Notes last week the Housing and Town Planning Bill of the President of the Local Government Board has been read a first time in the House of Commons. The second reading, which was down for April 1st, was postponed. The anticipations of those who expected that the Bill would contain drastic compulsory powers have not been realised, for its main features embody an extension and a simplification of existing powers. Whether this extension and simplification will arouse to a sense of their responsibilities the members of those sanitary authorities which have hitherto been notoriously inactive will depend in great measure upon the extent to which the Local Government Board and the county councils exercise the powers given to them by the Bill to enforce the execution of its provisions and the provisions of existing Housing Acts. The Local Government Board is given power after due inquiry to order a defaulting sanitary authority to carry out such works and to do such things as may be required to remedy the default. But it must not be forgotten that since 1875 the Board has been in possession of the same power to enforce the carrying out of the requirements of the Public Health Act of that year and has been singularly reluctant to exercise it. So reluctant that according to the latest records although, during the five years 1902–1906, at least 13 formal complaints were made by county councils and others of defaulting sanitary authorities in only one instance did the Board make an order upon the authority to carry out its statutory duties. It may well be asked, with this experience before us, whether the powers proposed to be given to the Board in connexion with the Housing Acts is likely to be any more effective than has been that which it already possesses as regards the Public Health Act. It is true that the policy of the Board has always been to effect reforms by persuasion rather than by compulsion, to convince of the necessity for reform rather than to coerce an unwilling authority to do that for which it either does not or will not see the need, and with this policy we are in entire agreement.

The improved conditions which are now to be found in every district are admittedly due to the system of education which the sanitary authority has been undergoing during the past half century at the hands of the Local Government Board and of sanitary officers generally. The fuller powers that are wanted are in the direction of increasing the facilities for this education rather than in adding to the compulsory powers of the Board. Included in these facilities is the appointment of properly trained sanitary officials who, having a special knowledge of the subject, will be able to give advice with a sufficient amount of authority to carry conviction with it. The necessity for the possession of this special knowledge has been recognised in the case of large districts or combinations of small districts to which can be appointed as medical officers of health only those who have a degree in sanitary science or a diploma in public health or State medicine, and during the past few years a very laudable and more or less successful attempt has been made by the Local Government Board to add to the number of these specially qualified medical officers of health by urging upon adjoining sanitary authorities the advantages of combination for the purpose of securing the services of one official devoting his whole time to public health duties. It is to be regretted, however, that the Board has not at the same time taken any steps to insure to the official when appointed a reasonable security against dismissal in the event of the advice which he tenders being displeasing to a majority of the electing body.

There are two clauses in the Bill which are calculated to do an immense amount of good but each depends for its successful application upon the effective initiation of the medical officer of health. Each clause is but an amplification of sections of the Housing of the Working Classes Act of 1890, and there can be no question that these sections have not been enforced as they might have been because of the conditions under which a medical officer of health holds office. If no alteration is made in this respect and he is still subject to reappointment year by year the clauses of the Housing Bill will be as ineffective as the corresponding sections of the Act of 1890. Clause 13, one of those to which we refer, is a repetition of Section 32 of the Act of 1890 with an important difference. In the latter the medical officer of health or other officer of the sanitary authority must convince not only the authority that a particular house is unsuitable for human habitation but he must also prove the same facts before a court of summary jurisdiction which alone has the power to make a closing order. The Bill dispenses with the appearance before the justices and enables the sanitary authority to order that a house shall cease to be occupied. But, as already stated, the first step towards condemnation and ultimate closing has still to be taken by an official dependent for his very livelihood upon the goodwill, it may be, of the owner of the condemned property. In the case of hopelessly uninhabitable dwellings obviously no difficulties arise but there are innumerable stages between the condition of a derelict cottage and that of one which is on the verge of becoming uninhabitable. The medical officer of health has to decide when the borderland has been crossed and it is intolerable that his decision should appear even to be biassed by the prospect of making one or more members of the sanitary authority hostile to his interests. Clause 26, which is an extension of the principle embodied in Section 75 of the Act of 1890, defines houses for the working classes as those with an annual rateable value in London of £40, in Liverpool, Manchester, or Birmingham of £20, and elsewhere of £16, and provides that in the case of such houses there shall be implied a condition that at the commencement of the tenancy they are in all respects reasonably fit for human habitation. Clause 27, which is entirely new, provides that in the case of the houses of the character named the implied condition of the tenancy shall include an understanding that the house shall during the holding be kept by the landlord in all respects reasonably fit for human expresses itself as very hopeful that its adoption will afford some relief to the rates by the prevention of insanity. We have no fault to find with this as a pious opinion but we hope that it does not foreshadow that the control of the institution by the County Council will mean primarily a desire to run it "on the cheap" out of consideration for the ratepayers. The proposed hospital will afford a great and useful experiment which should be favoured by every encouragement, and if there be any sign of the entry of cheeseparing into its administration it will confirm us in our opinion that the control of its destinies would be better in the hands of a body of independent governors looking to the charitable public to support an institution which might reasonably expect a widespread and practical sympathy from many generous persons.

THE METROPOLITAN WATER-SUPPLY.

THE report of the Metropolitan Water Examiner for December, 1907, is of double interest, as after the usual monthly record an elaborate appendix is added which gives very fully and carefully a digest and tabular summaries of the water examinations during the past year. A measure of the work which is entailed by the watchfulness of the Board's examiner is given by the fact that in 1907 the number of samples examined chemically was 3393 and bacteriologically 8950, which involved the use of 306,691 dilution and culture tubes. The chief advance in laboratory method during the year has been the adoption of Dr. A. C. Houston's quintuple preferential test for bacillus coli, and he now gives his results for that organism under the heading "Typical B. coli," which, he says, corresponds to "Flaginac B. coli" of last year. He has not discarded the old method as unsound but finds the quintuple tests more expedient for Board purposes. Whilst congratulating Dr. Houston on the elaboration of a useful method we regret as fully as he does its confirmation of the fact that London is served by a sewage-polluted water-supply. We commend the following digest of the B. coli findings for 1907 to the attention of our readers, many of whom they concern intimately:—

Source samples.	Percentage of samples found to contain bacillus coli *after filtration*, the samples being respectively of (*a*) 100 c.c., (*b*) 10 c.c., (*c*) 1 c.c., and (*d*) 0·1 c.c.			
	(*a*)	(*b*)	(*c*)	(*d*)
New River	9·8	4·0	0·5	0·06
East London (Lee)	10·9	2·7	0·8	—
East London (Kempton Park)... ...	11·5	0·8	—	—
Chelsea	8·1	2·2	0·6	0·1
Grand Junction	15·5	4·5	0·5	0·1
West Middlesex	14·3	6·1	0·8	—
Southwark and Vauxhall	22·7	12·7	3·4	0·5
Lambeth	14·1	5·5	1·4	0·3
Thames-derived water	15·5	6·3	1·3	0·2
Kent (*chalk wells* water, delivered unfiltered)	8·9	1·2	0·4	—

This table shows that with the single exception of Chelsea the unfiltered water from the chalk wells of Kent is considerably purer than any filtered river-supply. Chelsea water gives a much higher "total organic carbon" than the Kent supply, which, except for its extreme hardness, must be awarded the palm of excellence. The badly needed remedy is additional accommodation for storage and settlement, as the report points out in a paragraph which might almost be stereotyped, so often has it been printed. We hope this matter may find a speedy solution, and print the above table with the view of awakening attention to the fact that London water is very far, indeed, from bacteriological perfection. The figures for December are particularly bad, for only 54·4, 72·9, and 29·4 per cent. of the filtered water samples derived from the Thames, Lee, and New River respectively contained *no* typical bacillus coli in 100 cubic centimetre samples, whilst one cubic centimetre samples of these waters before filtration contained B. coli in the measure of 100, 100, and 81·2 per cent. respectively. Such results as these are under existing arrangements the inevitable sequence to a time of flood, and we can hardly hope for better things in the report for January, since the December rainfall was 4·13 inches and the Thames water at Hampton was reported "bad"—i.e., coloured and turbid—from Dec. 1st to the 18th, then "indifferent" until the 22nd, and "good" for 10 days of the month only. We have felt it our duty to dwell upon the least pleasant aspect of London's water-supply but in doing it we intend no disparagement whatever to the hard-working and often devoted manner in which the Board's engineers fulfil their duty, often in very adverse circumstances. None but the engineers can appreciate the difficulties in the way of securing a pure service and we are convinced that they systematically grapple with the task to the best abilities of the appliances with which they are equipped; but if London is to rely on a source of supply which is inevitably sewage-contaminated the onus is upon the responsible officials to provide appliances to render that contamination harmless, and above all to render the purity of the service more independent of flood time and drought time than is the case at present. Their own experts month by month are pointing out the means by which this end may be largely attained.

AFFORESTATION.

IT is announced that the labours of the Royal Commission on Coast Erosion are to be extended to the question of afforestation and the *personnel* of the Commission has been altered with that object. Long experience has taught us that reference to a Royal Commission is no guarantee that a particular question will be brought within the range of practical politics; nevertheless, all who are interested in the public health should welcome discussion of this subject. Although the influence of forest upon climate is likely to be exaggerated, there is no doubt that extensive woodlands tend to render the climate of a country more equable. According to observations made in several German forests it has been found that in the month of July the temperature of the soil beneath the trees was 7° F. lower than in the open field, whereas in December the forest soil was found to be rather warmer than the ground in more exposed places. It is also stated by geologists that trees tend to increase the precipitation of moisture, while Sir Archibald Geikie in his "Text-book of Geology" says that the destruction of forests is alleged to increase the number and the severity of hail-storms. The same writer tells us that in some parts of the world removal of trees has led to depopulation. Thus from 1836 to 1866 the departments of Hautes and Basses Alpes lost 25,000 inhabitants, or nearly one-tenth, of the population, a diminution which has been assigned to the reckless removal of the pine forests, whereby the steep mountain sides have been washed bare of their soil. Apart from the commercial aspect of the matter, the growth of timber on waste lands is also important in connexion with water for town supply and agricultural purposes. If the catchment area which supplies a particular stream is wholly bare of trees a sudden rain storm produces a flood which quickly passes away. But if, on the other hand, the hilltops are covered with vegetation, the woods and undergrowth act as a kind of sponge which parts with its moisture by slow degrees. In effect, the forest acts as a kind of natural reservoir. In these days, when the adequate supply of water to large towns is becoming more and more difficult, any of not exceeding six months and to a fine not exceeding £75; or to one of these penalties:—I. Any person advertising or recommending himself as being able to treat individuals at a distance (*Fernbehandlung*). II. Any person advertising or recommending remedies, articles, or methods directed to prevent, alleviate, or cure venereal diseases, to remove sexual impotence, or to promote sexual stimulation, to prevent conception, or to arrest pregnancy. III. Any person advertising or recommending remedies, articles, or methods for which it is claimed that they serve to prevent, alleviate, or cure human or animal disease, pain, and injury, where the ingredients or composition of the remedies or articles sold, or the essential features of the methods practised, are concealed or veiled from the purchaser or subject. The clauses (II.) and (III.) shall not be applicable to advertisements or recommendations inserted in medical, veterinary, or pharmaceutical journals.

If some such regulations as the above become law in Germany, or could become law in these islands, unqualified practice would receive a great set-back. Advertisement would become an expensive method of obtaining publicity and the necessity for disclosing the composition of the remedies would probably make would-be purchasers buy (for instance) the ordinary iron pills of the Pharmacopœia at about 1*d*. per dozen, instead of Bodger's Blue Boluses at 1*s*. 1½*d*. per box. But there is yet a simpler method of staying the noxious trade of secret medicines and of quack treatment, electrical and otherwise. We have pleaded for it on many previous occasions, for instance, in our issue of May 12th, 1906, p. 1365, and it is this. Any unqualified person claiming to be able to treat disease by drugs or otherwise should have to pay a heavy annual licence. It is beside the mark to say that such a licence would be a Government recognition of quackery, for quackery is perfectly legal now. Brewers, licenced victuallers, and tobacconists all have to pay a licence to carry on their trade, and such licence implies no guarantee of the purity of articles sold by them. If the tribe of quacks and patent medicine vendors had to pay a licence, which should be renewable annually, which should be revocable at the pleasure of the authorities, and which should cost not a paltry guinea but at least £500 per annum, a great step forward in the safeguarding of the health of the people would have been made. We commend this notion to the notice of Professor ROBERT SAUNDBY, a reprint of whose judicial and sensible paper[2] on the Amendment of the Penal Clause of the Medical Act lies before us.

◆

The Irish University Bill.

MR. BIRRELL, the Secretary of State for Ireland, appears to have produced a scheme for dealing with the Irish University question which bids fair to give sufficient general satisfaction to warrant not only a place on the statute-book but expectation that a settlement of a much-vexed question may be thereby arrived at. Under Mr. BIRRELL'S scheme, by which two new universities will be created for Ireland and one will be superseded, the Irish nation will be in possession of three separate teaching and examining universities, one of which will be rich, while the other two will have fairly substantial endowment. The difficulty in respect of creeds is solved, though solved in a way that cannot bring satisfaction to those who have the best and fullest conception as to the meaning of university education. Trinity College, Dublin, remains untouched, a position which it owes to its distinguished past. That portion of the Royal University of Ireland, now superseded, which had its seat at Belfast will be elevated into the University of Belfast, and a new university having its headquarters in Dublin will be instituted, of which Cork and Galway will be constituent colleges, while the Maynooth and Magee Colleges and the Catholic School of Medicine will be affiliated to it. The objection to the scheme in the eyes of all who have the highest type of university education before them as a model is that education in Ireland will remain parcelled out into water-tight compartments. Trinity College will receive the Episcopalians, the University of Belfast will receive the Presbyterians, and the new University in Dublin, as yet unnamed, will receive the Roman Catholics, and such separation of the holders of different creeds and observances from each other must detract from the universality of education, but the circumstances of Ireland well warrant Mr. BIRRELL making no futile struggle for the ideal. Mr. BIRRELL has done his best. There are to be no religious tests in the new universities and there will be some representation on the senates at Dublin and Belfast, both of Protestantism and Roman Catholicism.

The finest thing that can possibly happen for Ireland is the spread of education, and undoubtedly the Irish University Bill will help to place a liberal education before the middle-class youth of Ireland. The medical profession can hardly fail to benefit in the general improvement which will take place in educational standards and the diffusion of knowledge, and we look forward to seeing thoroughly well attended medical and scientific schools in connexion with all three foundations. If more money is needed to secure this end we hope that it will be freely forthcoming. It was impossible to suppose that the North of Ireland would view with complete approval Mr. BIRRELL'S scheme or the way in which the funds for carrying it out were allocated. The £20,000 annually given to the Royal University of Ireland will now be divided between the new university in Dublin and the University of Belfast, while Belfast will receive a further grant of £28,000 per annum and £60,000 for building and equipment and Dublin will receive £32,000 per annum and £150,000 for building and equipment. The attitude of the Royal College of Surgeons in Ireland towards the establishment of a new and endowed medical school almost at its door could be anticipated. The medical school in connexion with the Royal College of Surgeons in Ireland can hardly fail to be damaged to some extent by competition with the endowed medical school of the new university, and we trust that Mr. BIRRELL will see his way to compensate the College for any injuries which it may receive. Mr. BIRRELL has been approached in this sense already, and there may even now be definite proposals set on foot for safeguarding the interests of the distinguished Irish corporation. In a Bill which has been so obviously inspired by a desire to please everybody there should be no element of discord which can be eliminated.

THE Earl of Cranbrook has become a Vice-President of the Royal Sea Bathing Hospital, Margate.

---

[2] Read before the Midland Medical Society on Jan. 29th, 1903.

Society presented to the city council a site of 1000 square yards in Tower-street and at a cost of £282 it has been converted into a playing area which is enlivened and decorated by a fountain and an inclosure containing trees and shrubs. In Musgrave-road the city council purchased two acres at a cost of £2748 and by the expenditure of £1207 a miserable and depressing area has been transformed into a pleasant oasis. The lower part of the area has been made into a playground for children and the upper part into a lawn with flower-beds and trees. Thus at a comparatively small cost there have been placed in the midst of monotonous surroundings two pleasant open spaces where the older inhabitants of the surrounding dingy streets may enjoy greater breathing space and pleasant glimpses of grass, trees, and flowers, and the children will be able to expand their lungs with purer air and exercise their limbs with greater freedom. It is by well-advised policy of the type which has resulted in the provision of these two new lungs for Birmingham rather than by oppressive legislation that the ideal of life will be raised and many of our present infirmities swept away.

CROPPER v. STOKES: A JUDGE'S QUALIFIED APOLOGY.

WE commented strongly last week upon the action of his honour Judge Edge, who inferentially accused Dr. Henry Fraser Stokes, a well-known Highbury physician, of perjury in giving evidence in the case of Cropper v. Stokes. The accusation was a careless and cruel one and was made infinitely worse by the refusal to Dr. Stokes of the right to appeal against the decision given, thus depriving him of the chance of contradicting the opinion of the judge that he was a thoroughly wicked and disreputable person. A qualified apology has been obtained from Judge Edge under considerable pressure. A memorial was presented to him at the Clerkenwell County Court on Monday last signed by influential members of the medical profession pointing out how impossible it was that Dr. Stokes could have committed perjury. Mr. H. F. Dickens, acting for the Medical Defence Union, read the memorial to Judge Edge who said that in the course of his experience he had never heard of a similar proceeding. Judge Edge then said that he was pleased to get the memorial because if he had unintentionally done a wrong he was glad to be set right. He admitted that upon reflection the evidence given by Dr. Stokes before him upon which he had commented so strongly now appeared to have been given under misapprehension but in the belief that it was true. He could not have said much less or made a less strenuous attempt to remove from Dr. Stokes the slur of a particularly grave accusation. The memorial was in his hands two days before it was read in court and his honour's reply was made, we understand, from a written document. But such as this reply is, it forms an apology and we congratulate Dr. Stokes upon receiving it. Fortunately all who know Dr. Stokes knew that the judge had made a grave error.

THE LATE DR. JAMES BELL.

THE death occurred at his Hove residence on March 31st of Dr. James Bell, C.B., D.Sc., Ph.D., F.R.S., who for 19 years—from 1875 to 1894—was the principal of the Somerset House Laboratory after being deputy-principal for seven years. Born at Armagh in 1825, he was thus 83 years of age. He was at first educated privately and later gained the honour of gold and silver medallist in chemistry at University College, London. While holding the position of deputy-principal of the Somerset House Laboratory he was appointed, in 1869, as inspector of lime and lemon juice for the Board of Trade. This appointment he held for 25 years—from 1869 to 1894—and for the same period he was consulting chemist to the Indian Government. From 1875 to 1894 he was chemical referee under the Sale of Food and Drugs Act, and from 1888 to 1891 was president of the Institute of Chemistry. He was made a C.B. in 1889. Dr. Bell published in 1883 "The Chemistry of Foods," a well-known work on original researches. It was adapted as a handbook for the South Kensington Museum and was translated into German.

* A day with at least 0·04 inch.

Contrary to the usual course of events the temperature in this country made a retrograde movement during March and its general level was not only below the average but also below that of the month immediately preceding. Over the southern regions of Europe, however, although the climate was not at all warm for the time of year, it was less cool than during February. Both at home and abroad rain was of frequent occurrence, the only exceptions being at Nice, Malta, and Lisbon. At Nice the seven days with rain shown in the above table represent the only rainy days which that resort has experienced during the present year. Along the south coast of this country the sunshine was rather above the average duration, the highest figures being 149 hours at Torquay and 150 hours at Sandown, Isle of Wight. The Scilly Isles had exactly the same mean temperature as Nice but while at the French resort the average day was as mild as 53° and the average night as cold as 39° the corresponding figures at Scilly were 50° and 42°. On the south-western coast of England, Torquay, with a mean temperature of 43·2°, was the mildest, but Plymouth was very little cooler, and Sandown, I.W., had a mean of 42·7°. At Biarritz the nights were rather cool, cooler than during February, and the mean temperature, 47·3°, only a trifle higher than the inland resort of Florence. The highest mean temperature and the mildest nights were experienced at Malta, and the diurnal range of temperature was only 8°, the same as that at Scilly. Among the inland unsightly than it was before. It is fully determined now that x rays should never be used for the removal of superfluous hairs from the face. The best method for the permanent removal of hairs from the face remains to be mentioned, and that is electrolysis, but this method, too, is by no means free from danger and in the hands of the ignorant the electrolysis can do much harm. It was first employed by Michel for removing ingrowing eyelashes, and Hardaway first used it for removing superfluous hairs from the skin. It is essential that the needle should be attached to the negative pole, for if the needle is steel and it is attached to the positive pole very unsightly black stains will be produced, and these are permanent; in fact, a tattooing has been performed. It is very important that so far as possible the process should be aseptic; the patient's skin and the needle must be carefully cleansed or suppuration may occur. If hairs too close together are operated on at the same sitting the intervening tissue may slough and a scar may follow; and even when no definite scars result chronic septic processes may follow leading to the production of wrinkles and furrows which detract greatly from the appearance of the face; even keloidal growths have been reported. It will thus be seen that the electrolysis of superfluous hairs requires just as much care and skill as many minor surgical operations. It is, indeed, a surgical operation and it is not right that it should have fallen into the hands of "beauty specialists" and "manicurists." The public is led to think that it is an unimportant procedure but it has possibilities of harm which are undreamed of by the patients and often by the operators themselves. It may well be that a careless or ignorant operator may render a face markedly unsightly which previously to the operation had shown merely a few dark hairs. Unless the hirsuties definitely spoils the appearance of the face it is well for the patient to rest content with milder methods than electrolysis.

AFTER-HEALTH OF UNIVERSITY OARSMEN: AN OLD STORY.

THIS which follows is an old story; it need scare no relative of either of the crews whose gallant struggle last week engrossed so much attention. It is now more than 40 years since F. C. Skey, ex-President of the Royal College of Surgeons of England, wrote to the *Times* to prove that, in his experience and that of many of his colleagues, the constitutions of an appreciable number of the rowers in the Oxford and Cambridge University boat-race had undergone permanent damage from over-exertion during the contest. The letter aroused lively controversy and led in 1873 to the publication by Dr. John Edward Morgan of "A Critical Enquiry into the After-Health of the Men who Rowed in the Oxford and Cambridge Boat-Race from the year 1829 to 1869." The work contains many letters from former oarsmen, most of which testify to the good effects produced upon them by hard rowing. Some writers, however, complain of heart weakness and digestive troubles set up in the first instance, so they believed, by over-exertion during and before the race. The following table has been compiled from Dr. Morgan's accurately obtained statistics. It differs slightly from his own published table. The 17 cases of injury are mainly attributable to heart disease, but are not fully discussed. In drawing a lesson to-day from these details it should be borne in mind that some of the early races were more than five miles long and that full trials were rowed daily for some ten days before the race. Would it be possible for someone to undertake a similar investigation into the physical state of the competing Blues from 1869 onwards? The information would be, we believe, reassuring and very interesting if the deductions drawn from it are not of too sweeping a nature, and if the matter were compiled on a more comprehensible plan. Let us guess that the two crews of 38 years would give us from 350 to 400 different individual men whose history would have to be inquired about, the rough total being arrived at by surmising that nearly half the men take part more than once in the struggle. The effects of the physical and the mental strain upon 400 young men all about the same age and all to a large extent drawn from the same class and all embarking in the same circumstances upon the same contest are certainly worth noting from a medical point of view. All the evidence that would be obtained would not be of equal value and some would be worth very little, but suggestive facts would certainly be forthcoming. Dr. Morgan's statistics have one source of confusion—the same man may be counted in them more than once, so that (for example) the three men who are put down as injured in 1864 may some or all of them have been put down as benefited or uninjured in 1861, 1862, and 1863. Dr. Morgan's figures show 17 cases of injury out of 416 men, but 416 different men did not take part in the races, though 16 men competed in each year.

THE PROPOSED NEW HOSPITAL FOR MENTAL DISEASES.

OUR readers will remember that the asylums committee of the London County Council has recently had under consideration the munificent offer of Dr. Henry Maudsley to contribute £30,000 towards the cost of the erection and equipment in London of a hospital of 100 beds for the treatment of cases of recent and acute mental disorder. We commented upon the matter in a leading article in THE LANCET of March 7th, p. 728, in which we set forth the reasons which led to the offer being made. These have been accepted as convincing by the committee of the London County Council to which the matter was referred, and it has now recommended that the £30,000 be accepted from Dr. Maudsley and that an equal sum be contributed by the Council which will maintain the institution when completed. The committee fully endorses the scientific and humanitarian advantages which the author of the scheme claimed for it and due to cancer of the brain. This appeared to be secondary to cancer of the stomach, for a lobulated tumour was found in the epigastric region. The gastric cancer was almost entirely latent. Questioning of the patient showed that slight pains had begun two months previously and that she occasionally vomited. Her condition remained stationary until Oct. 24th when the temperature rose to 104° F. and she suddenly became comatose and died in a few hours. On opening the cranium the brain and its membranes appeared normal. In the left internal capsule was a greyish-yellow spot one centimetre in height and one and a half centimetres in breadth with a finely indented contour. Serial sections showed that it extended for a distance of three and a half centimetres, invaded the optic tract, and abutted on the ventricle. The remainder of the central nervous system was normal. Microscopic examination of the cerebral growth showed that it was composed of cells similar to those found in the cerebro-spinal fluid. There was also a large cancer of the stomach with secondary growths in the omentum, mesentery, liver, kidneys, lungs, and mediastinum. In the heart a very rare lesion was found, a fungating cancerous growth of the size of a large pea on the posterior sigmoid valve similar to the growths found in infective endocarditis. Microscopic examination showed that this growth had the same structure as the vegetations of infective endocarditis with the difference that microbial infiltration was replaced by infiltration of cancerous cells. The growth was composed of filaments of fibrin inclosing masses of cancer cells. It is noteworthy that leucocytes were absent from the cardiac growth and also from the cerebro-spinal fluid, although the cancerous cells played the part of infecting elements.

PARISIAN MEDICAL MEN IN THE SIXTEENTH CENTURY.

AT a recent meeting of the French Academy M. Babelon called the special attention of the members to a work by M. Émile Rivière which contained the first portion of a "Histoire de la Médecine à Paris, au XVI^{e}. Siècle, et ses Praticiens." These latter include ordinary medical men, barber-surgeons, medical students, and apprentices to the barber-surgeons. The materials for the treatise are almost all derived from the "Recueil d'Actes Notariés" relative to the history of Paris and its environs from 1513 to 1545. These archives furnish particulars of cases which came under the supervision of the Paris Faculty of Medicine, especially in 1528 and 1541; also of certificates of the occurrence of certain diseases, of indentures of apprenticeship to celebrated barber-surgeons, and of certificates of competency and permission to exercise the profession of surgeon. This portion of M. Rivière's book terminates with a list of 83 practitioners of the remedial arts, most of them citizens of Paris, together with their professional titles such as "docteurs regents"; premiers médecins, or médecins ordinaires du roi; chirurgiens jurés, and others, adding also their Paris addresses and the signs which they were entitled to suspend outside their residences. Among these medical men appears Master Charles Estienne, brother of the celebrated printers and publishers of Paris. This gentleman dwelt, in 1542, in the Rue Sainct Jehan de Beauvois, at the sign of King David, and appears to have had a large practice.

Mr. Arthur Ferguson MacCallan, M.B., B.C. Cantab., F.R.C.S. Eng., chief ophthalmic inspector in the Public Health Department of the Egyptian Government, has received His Majesty the King's Royal Licence and authority to accept and to wear the Insignia of the Third Class of the Imperial Ottoman Order of the Medjidieh conferred upon him by His Highness the Khedive of Egypt in recognition of valuable services rendered by him.

A COMMUNICATION from the Colonial Office dated April 1st states that during the week ended March 28th the Governor of the Gold Coast has reported 2 deaths from plague near Oblogo. There have been neither cases of, nor deaths from, plague at any other place in the colony. The Department of Public Health of Queensland, in a bulletin dated Feb. 29th, states that no case of plague has occurred in Brisbane since Feb. 7th.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

BY the kind invitation of Mr. Johnson, of Messrs. Humber, Limited, I recently had a trip in a 10–12 horse-power Coventry Humber, and I must say that though I have used a car now daily for over eight years I have never more thoroughly enjoyed a drive. The car, which seems an ideal one for a medical man, is only just over 11 feet long and so permits of easy manipulation; and as a leather hood and front wind screen are fitted there is complete protection from rain and wind. The silence of a Humber is proverbial and is secured by the use of a four-cylinder engine which, of course, makes starting a very easy matter, certainly an important point for a man who drives himself. In the old days I well remember frequently letting a Benz that I then had thunder away while paying a professional call, so as to avoid having the bother of opening the back and spoiling either my gloves or making my hands filthy in pulling the fly-wheel round, and it did require pulling; now this little Humber nearly always starts on the switch and only occasionally does it need a turn of the starting handle. I found that by opening the throttle fully and then switching off, the engine invariably started when the electricity was turned on, and I can with feeling say that this is a boon. The engine has a 3¼ inch bore and a 3¾ inch stroke and is usually run at a speed of about 1200 revolutions per minute. Lubrication is by splash in the crank chamber, the oil being delivered by hand pump on the dash-board, a drip sight feed being fitted for the pump spindle as well as for the clutch and gear box. The makers realising the importance of thorough attention to proper oiling and the unfortunate fact that the general public do not pay much regard to it, issue a sheet with each car sent out, showing those points that need daily visits from the oil-can, as well as such as require but an occasional drop. There is little question that well-designed automobiles need little attention beyond periodical and thorough lubrication, and though a great deal is automatically carried out, still there are many parts that cannot be so greased and it is the owner or driver who makes this duty a matter of methodical inspection, counting off each item as it is attended to, who is free from involuntary stops and whose car works the smoothest and is not a frequenter at the motor doctor's. The great thing is to use good oil and to see that it reaches the parts it is intended to. Lubrication pipes are all the better for an occasional clean out with the tyre pump or by taking them down and holding the centre of the pipe over a gas flame, as the heated air cleans by driving out foreign bodies, such as dirt, dust, and thickened dried oil. On some of these cars the oil is forced by pressure from the exhaust, and naturally, if the pressure-conveying pipe is blocked the oil is not speeded on its way. On this latest type (Humber) a pump lubricator is fitted and driven by a band from the two to one shaft, but either form is successful provided it receives occasional attention. The driving band may break or become too slack, simple disorders that once seen can be quickly remedied. The carburettor is the new type of Longuemare and seems to give a perfect mixture at all engine speeds; it has a hand air regulator, which is an advantage as by its use the mixture need never be "too rich." I certainly do ascribe the now general need of taking off the cylinder covers so as to remove soot deposit to the modern automatic carburettor, which so easily gives too rich a mixture, with resulting carbon deposit on the piston or in the combustion head. This deposit readily agency which will operate to prevent water finding its level too soon cannot fail to be beneficial.

RECENT OBSERVATIONS ON THE TSETSE FLY.

As the subject of sleeping sickness attracts much attention at the present time, our readers will be interested to hear the results of an inquiry undertaken by Mr. E. A. Minchin, the professor in the recently established chair of protozoology in the University of London, on the trypanosomes of the tsetse flies and other diptera. Mr. Minchin went to Entebbe in Uganda in April, 1905, and stayed there until December. The commission with which he was specially intrusted was to study the life-cycle of the trypanosoma Gambiense in its relation to the local species of tsetse fly (glossina palpalis), but this investigation proved barren of results or yielded conclusions chiefly of only a negative character. Incidentally, however, he made some observations on another species of trypanosoma occurring in the tsetse fly which he thinks may prove useful as a guide to future investigators. Mr. Minchin's colleagues, Mr. A. C. H. Gray and Mr. M. G. Tulloch, who preceded him in investigations on the trypanosomes of the tsetse fly, found swarms of "wild" trypanosomes in the alimentary canal of freshly caught specimens of these flies. These they at first considered to be stage in the development of the trypanosoma Gambiense to which sleeping sickness was attributable. Mr. Minchin's investigations, however, with those of his colleagues speedily led them to the conviction that the "wild" trypanosomes had nothing whatever to do with the trypanosoma Gambiense and constituted another species to which M. Mesnil had previously applied the name of Grayii—the trypanosoma Grayii. Mr. Minchin made a preliminary study of the anatomy of the glossina palpalis and in this article corrects some errors into which he had previously fallen. Thus he recognises in the alimentary tract a proventriculus, thoracic or sucking stomach or crop, which after the animal has fed contains bright red blood; a true stomach which is the first part of the digestive tract in the abdomen and in which the blood still retains its bright-red tint but becomes thick and jelly-like; and to this succeed the coils of the true intestine in which the ingested blood becomes dark, very fluid, and watery, with fewer red corpuscles and often with numerous square crystals in it. The black blood stops short at the point where the Malpighian tubules arise and where the proctodæum commences. The proctodæum contains no blood but a yellowish fluid in which are suspended numerous coarse granules showing Brownian movements. Thus the abdominal gut exhibited some time after the fly was allowed to feed three regions well defined by their colour—the red stomach, the black intestine, and the yellow proctodæum. The fluid used for examination of the fly for trypanosomes was withdrawn from the pericardial space by means of a capillary tube; it was found that except for bacteria the tsetse fly was very free from internal parasites; no gregarines or other sporozoa were found in the trypanosomes. The trypanosome body is fusiform and transparent, and presents near the middle of the body a nuclear apparatus which he thinks is specialised into two distinct portions—a kinetonucleus regulating the function of locomotion and a trophonucleus controlling nutrition. There is also a basal granule giving origin to the flagellum. The basal granule is a true blepharoplast, which gives origin to a flagellum—a whip-like body that runs along the edge of an undulating membrane—and is here named the marginal flagellum, and becomes free at the anterior end of the body. In all cases alike the trypanosomes are distinguishable by their general build and appearance into slender, stout, and intermediate forms. The slender forms are actively motile and the stout are listless. The slender forms have a long free flagellum in the cytoplasm and the stout forms have a short one. The anterior end of the body is prolonged into a slender filament running for some distance along, or even to the end of, the flagellum. Vacuolation is occasionally to be observed but probably indicates an abnormal condition. There seems to be little doubt that sleeping sickness is due to the presence in the blood of the trypanosoma Gambiense, and it is equally certain that the tsetse fly, named by entomologists the glossina palpalis, is the active agent in conveying the infection, but some obscurity still exists in regard to the precise mode in which that infection is transmitted. It has been shown by Ross, Grassi, and others that in malaria the mosquito is a true host in which the parasite goes through a complicated developmental cycle at the close of which, but not before, the mosquito is able to infect a fresh vertebrate host with the parasite. This mode of infection, Mr. Minchin suggests, may be characterised as the "inoculation cyclical" type. But in the case of infection through the trypanosoma Gambiense the type seems to be a different one, the protozoon being inoculated mechanically by the proboscis of the blood-sucking fly, and it may be observed that the capability of infecting a vertebrate animal only lasts for a period of 48 hours; with a longer interval no infection was obtained. It is interesting to notice also that freshly caught flies may produce infection with trypanosomes without having been fed previously upon infected animals. The experiments made upon monkeys show that many freshly caught flies are free from the infecting agent or that some monkeys are immune. Thus in one case 2299 flies were fed on a monkey over a long period without infecting it, whilst in another case as small a number as 134 flies produced an infection in it. When infection did take place it occurred much more rapidly with the freshly caught flies than with those that had been fed upon animals affected with trypanosomes. In experiments made with flies fed on an infected animal and transferred at once to a healthy animal Mr. Minchin found that he could infect nine out of ten animals each with a single fly. The origin of the trypanosomes that multiply with such rapidity in the blood of vertebrates is unknown but it seems probable that they are derived by the fly from infected vertebrates; but if taken from the intestine of the fly and artificially injected into susceptible hosts they will not infect them. Infection is apparently produced only by the trypanosomes in the proboscis of the fly. But different species of fly contain trypanosomes of very different degrees of virulence. In the second part of his memoir Mr. Minchin records his observations on the development of the trypanosoma Gambiense in the tsetse fly (glossina palpalis) and other diptera. The trypanosomes at first multiply in the digestive tract, and only in this when the digestion of blood is proceeding. The appearances presented are represented by Mr. Minchin in several plates containing a large number of beautifully executed drawings. The above observations are contained in the March number of the *Quarterly Journal of Microscopical Science* for 1908.

SOME RESULTS OF THE "OPEN SPACES" MOVEMENT IN BIRMINGHAM.

DURING the past year or two the Birmingham Open Spaces Society has by its energy and determination forced itself prominently into public notice and has consequently been subjected to both criticism and praise. Now that the results of its efforts are becoming more obvious to the ordinary observer there can be little doubt that they will receive even fuller appreciation than in the past. Anyone who visits Tower-street and Musgrave-road, where recreation grounds have been recently opened, cannot but be struck with the advantages which must accrue from the action which has been taken. In 1906 the Open Spaces

Mr. O'Gorman suggests in chain-driven cars to alter the sprockets and have the small one on the road wheels and the larger one in front, the ratios in the gear box being increased to compensate; thus there are two skids simultaneously and in opposite directions which cancel one another, and in shaft-driven cars he proposes to overcome the difficulty by employing two universal joints and a parallelogram of radius rods. Certainly, even if this makes the car dearer, the saving in tyre wear will make up for the additional primary cost. He also advocates a most important matter—care in letting in the clutch and discretion in the use of the brakes, all points which if attended to help to keep down tyre expense.

While recently touring I came across a fellow motorist on the road who was stuck up by a broken valve spindle. He had a spare one but seemed to have a difficulty in replacing the spring, and as the following wrinkle was not known to him I am giving it in case there are others to whom it may be also new. Compress the spring in a vice, or if you have not one handy an ordinary coach-house or shifting spanner will do. When it is compressed tie it with either a bit of string or wire, so that it cannot expand; it can then easily be put into position, and after the key is put in the wire can be clipped or the string cut. This dodge can, of course, also be used for clutch springs.

PETER OF ABANO.

BY CUTHBERT E. A. CLAYTON,

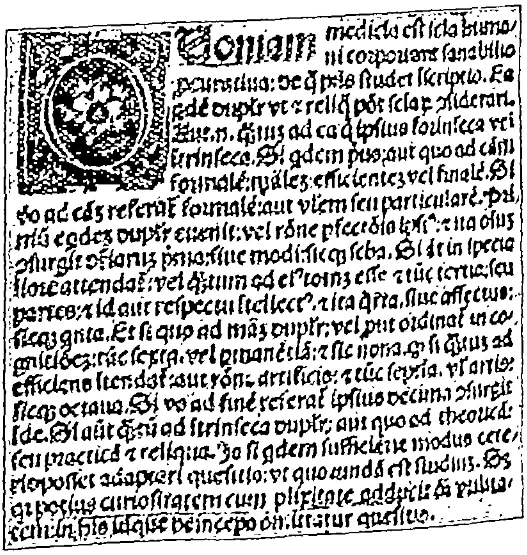
LIBRARIAN TO THE MANCHESTER MEDICAL SOCIETY AND OF THE MEDICAL LIBRARY, UNIVERSITY OF MANCHESTER; SOME TIME IN THE LIBRARY OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON.

OF the many physicians who flourished during the latter half of the thirteenth century and the beginning of the fourteenth century none gained a more widespread reputation than Peter of Abano, or as he was called Petrus de Abano. Born in 1250 at Abano, a village near Padua, the son of a notary, he soon gave evidence of an exceptional ability for study, and the earliest record we have is that of his leaving for Constantinople in order to devote his energies to the study of Aristotle; it is even said that he travelled into Greece for this purpose. Like so many students of his age he wandered from *studium* to *studium* until he reached Paris, where he settled for some years, devoting himself to medicine and mathematics, a combination rendered necessary by their common relationship to astrology. Astrology was an important part of a doctor's equipment. In addition to these three subjects he applied himself to physiognomy, geomancy, and cheiromancy, but with the advance of years he laid them aside.

The greater part of Peter's work was done whilst in Paris, a period extending from 1292 to 1303. He graduated in medicine, lectured on philosophy, wrote the "Decisiones physionomicæ," the "Conciliator," and commenced the "Expositio problematum Aristotelis." Of course, all these works were in MS. form, printing being an invention of 150 years later. Immediately on the appearance of the "Conciliator"—probably in 1303—the Dominicans accused its author of magic and heresy. Peter, however, defended himself brilliantly, confounded his accusers, and hastened to Rome, receiving from Pope Boniface VIII. a decree of absolution. Year by year Peter's reputation as a physician had spread throughout Europe. In 1306 he returned to Padua at the invitation of the University, where a chair of medicine is said to have been founded for him. Whether he previously, concurrently, or ever held a chair at Bologna, as has been stated, is uncertain, but I think it is improbable. The University at Padua came into existence in 1222, "when gown and town" warfare raged furiously in Bologna, resulting in a partial migration of the staff; such an act would not be lightly forgiven.

In Italy almost supernatural powers were credited to Peter and in 1306 he was brought before the Inquisition on the old charges of magic and heresy. For the second time the Dominicans were his accusers, now undoubtedly strengthened by the fact that Boniface VIII. had been succeeded by one of their own order, Benedict XI. However, it only added to the great reputation of the accused, for with great ability he proved his innocence. Eight years later he came into collision with the Church for holding heretical views on the resurrection of the dead, the existence of the devil, and miracles. Peter's good fortune remained with him until the end, for he died in 1315 before the completion of the trial, and was buried with great pomp in Padua. The inquiry was continued, its subject was found guilty, and it was resolved that his body should be exhumed, publicly burnt, and his property devoted to the use of the Church. What exactly happened is uncertain. The General of the Augustinians wrote: "He lied in his iniquity and received the reward of his error, for I was present when his bones were burnt in the city of Padua for these and his other heresies." Another version is that a faithful servant, informed of the sentence, disinterred the body during the night and transported it to another church necessitating his being burnt in effigy.

The more important literary remains of Peter of Abano are the following: "Decisiones Physionomicæ," "Expositio problematum Aristotelis," "Conciliator differentiarum philosophorum; præcipue medicorum," "Tractatus de venenis," "Quæstiones de febribus" (in a work "De febribus"), "Textus Mesue emendatus," and "Geomantia." He also edited and translated several *Greek* and *Hebrew* works. Unlike Vesalius or Mundinus, he added little to contemporary knowledge and undoubtedly *owed his popularity to* the controversial nature of his writings. His chief book, the "Conciliator," and the one to which he owed his reputation and sentence, was first published at Mantua in 1472, about 20 years after the first book printed with moveable type. I have been unable to refer to a copy of this edition. *The Manchester Medical* Society possesses a copy of the Venice edition of 1496, a folio of 265 leaves, which include the "Tractatus de venenis." It is printed in Gothic type in double columns. The printer was Octavianus Scotus, a native of Modena, who opened his press at Venice in 1480, founding one of the largest printing and publishing houses in that city. The accompanying passage is reproduced from a photograph of a portion of the Prologus:—



⁂ Without the contractions the above passage stands thus in transliteration, and we must express our thanks to Dr. L. G. Guthrie and Miss E. J. Lewis for help in the same:—

Quoniam medicina est scientia humani corporis ut sanabilis procurativa de qua praesens studet inscriptio. Ea quidem dupliciter ut et reliquae possunt scientiarum considerari. Aut enim quantum ad ea quae ipsius forinseca vel intrinseca. Si quidem prius aut quo ad causam formalem, materialem, efficientem vel finalem. Si vero ad causam referant formalem aut universalem seu particularem. Primum equidem dupliciter evenit, vel ratione perfectionis ipsius et ita omnium consurgit differentiarum prima, sive modi sicque secunda. Si autem in specialiore attendant vel quantum ad eius totum esse et tunc tertia seu partes et id aut respectu intellectus et ita quarta, sive affectus sicque quinta. Et si quo ad materiam dupliciter vel prout ordinetur in cognitionem tunc sexta, vel permanentiam et sic nona quae si quantum ad efficiens intendant aut ratione artificis et tunc septima, vel artis sicque octava. places in the north London was the mildest and Harrogate the coldest, while Manchester and Bath were very little colder than Paris and milder than Berlin and Brussels.

IMPURITIES IN AIR.

THE interesting researches of Professor William Thomson, F.R.S.Edin., into the amount of carbon dioxide in Manchester air and in buildings under different conditions, of which he gave an exposition at the meeting of the Manchester and Salford Sanitary Association, call for more than a bare mention. They grew out of the request of the Sanitary Association for a simple method of estimating the carbonic acid gas in public and other buildings, and the device contrived seems simplicity itself. The air is forced into a bottle with an ordinary pair of bellows and then submitted to a simple chemical test. The results of the analyses of air from various buildings taken sometimes when occupied and sometimes when empty are at times unexpected, and these researches not only widen our knowledge of facts but lead to a better understanding of the principles that should underlie schemes of ventilation. Modern architects, it seems, accept as permissible in buildings 6 parts of carbon dioxide in 10,000 but the variations from this standard are very wide. The lowest example given is from schools at Macclesfield where the range was 1·4, 3·5, and 6·1 in 10,000. In Manchester two boys' schools gave 11·2 and 11·7, and one of the girls schools gave 14·9, while two rooms in another school gave respectively 12·8 and 8·3. In a school at Openshaw the boys room showed 18·2 and the girls' room 11·5. The recently built Technical School came out better, giving 6·5 per 10,000. In a Nonconformist chapel near Manchester the air after service yielded the very great proportion of 44 parts of carbon dioxide per 10,000. In a concert hall 5·2 before a performance became 11·2 after one and a quarter hours, and so on. One interesting and important fact brought out in these experiments is that the sense of comfort and satisfaction experienced does not depend altogether on the proportion of carbonic acid gas present, for though the Technical School is one of the best ventilated buildings in the city many people find the air objectionable from its "lack of invigorating qualities," and this Professor Thomson believes to be due to the method of washing the air that is employed. That this is probably true appears from experiments made as to the effects of breathing dry or damp air, for it was discovered that "thoroughly dried air has a much more powerful oxidising influence on the blood than air that has not been dried, and that this effect is increased by heating the air." He referred to the air of the House of Commons having "a peculiarly flat taste"—though that does not appear to prevent it being much sought after—to its not being invigorating, and to the prevalence of influenza among the occupants. This he considers due to the air being washed in water as it is forced into the House and suggests that it would be much healthier and pleasanter to breathe "if it were passed through strong vitriol or some substance that would absorb the moisture." Other interesting points were brought out. The amount of carbon dioxide exhaled with the breath is usually given as about 4 or 5 per cent., but Professor Thomson found that "it depended on the quality of the air by which he was surrounded." Thus in Manchester a lower percentage of carbonic acid gas was given off than in the country, at the Buxton golf links, 1000 feet, and still more at the Cat and Fiddle, 1700 feet above sea level. But the idea that altitude influenced the amount of gas exhaled was not borne out, as equally good results were obtained at Blackpool. Professor Thomson found that where the air was inhaled through the mouth the expired air was about 0·2 per cent. lower in carbon dioxide than when the nostrils alone were used, and this suggested the idea that if the air were heated artificially still greater oxidation would take place in the body. It was found that when air heated to 140° C. was breathed the exhalation contained 5·4 per cent. of carbon dioxide, while exhalation of unheated air from the same person gave 4·4. The average of a number of experiments gave 4·1 from ordinary air and 5·2 from heated air. It is curious, and not what many of us would have anticipated, to learn that when pure oxygen was breathed the exhaled air gave an average of 4·4 to 4·5, considerably below that found from breathing in country air, so that Professor Thomson concludes that the ideal combination for reviving people nearly drowned or asphyxiated would be obtained from warmed country air and oxygen. Dried and heated air has a much more powerful oxidising influence on the blood than damp air, for the moisture more than neutralises the effect of the warmth. To illustrate practically the application of the exposition to which the audience had listened, a sample of the air of the room in the town-hall where the meeting was held was taken by Professor Thomson's assistant before the people assembled and by Professor Thomson during his address, the first sample containing 6 parts and the second 19·8 parts of carbon dioxide in 10,000. These investigations help to explain some of the influences of climate and locality more clearly than before. As is well known, however, the carbon dioxide is not the only cause of mischief from bad ventilation, the animal matters given forth with the breath being still more deadly. It is much to be hoped that Professor Thomson's paper will be carefully considered and its lessons acted on by architects, school managers, and all who are interested in the sanitary welfare of he people.

DIAGNOSIS OF CANCER OF THE CENTRAL NERVOUS SYSTEM BY LUMBAR PUNCTURE.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Feb. 28th M. F. Widal and M. P. Abrami reported a case in which cancer of the central nervous system had been diagnosed by lumbar puncture, a new and interesting application of this means of diagnosis. A laundress, aged 47 years, was admitted into hospital on Oct. 19th, 1907. Three days before whilst at work her legs suddenly gave way and her left arm became paralysed. She did not lose consciousness and got up in a few minutes with paralysis of the left leg, arm, and face. Examination showed left inferior facial paralysis and complete flaccid paralysis of the left arm and leg. The plantar reflex was of the extensor type. Sensibility was intact. There was nothing to show the cause of the hemiplegia; no symptoms had preceded it. Lumbar puncture yielded perfectly clear cerebro-spinal fluid, the tension of which was not increased. Centrifugalisation gave an unexpected result: instead of the lymphocytes found in various affections of the central nervous system the deposit was almost entirely composed of cells which in size, structure, and appearance of the nucleus had all the characters of cancerous cells. In the fresh state without staining they were seen to be rounded and huge; the smallest were four or five times the size of a polynuclear cell. The greater part of the cell was occupied by a vesicular rounded nucleus containing several very refractile nucleoli. The protoplasm of the cells was clear and in a great number contained numerous vacuoles; others were full of large granules. Some appeared to be in a state of karyolysis. The cells gave the glycogen reaction. In stained preparations numerous cells were found to be in a state of karyokinesis. The cerebro-spinal fluid contained a high proportion of sugar—four grammes to the litre. Clinically the case appeared to be an example of ordinary hemiplegia but the examination of the cerebro-spinal fluid showed that it was by King Edward's Hospital Fund could be made applicable to the requirements of provincial hospitals and to make recommendations to the next conference.

County Hospital Guilds.

Mr. R. H. KINSEY (Bedford County Hospital) discussed the organisation of county guilds for the support of hospitals, as in Bedfordshire, as an alternative to the extension of the work of the League of Mercy in the provinces. He proposed a motion approving of the scheme adopted by the Bedfordshire County Hospital. This institution supplied the hospital needs of an area containing 150,000 people. Every year it treated about 1000 in-patients and 5000 out-patients. The guild gave an opportunity to a large number of people to do good to their neighbours, it increased the annual income of the hospital by gathering in a large number of small subscriptions, and it increased the utility of the hospital by doing supplementary charitable work. Their idea was to secure in every little town and village throughout North Bedfordshire some representative of the hospital who would be constantly bringing its claims before his or her neighbours.

Lord AMPTHILL (chairman of the Bedford County Hospital) said the proposal was simply a measure for coördinating and systematising existing efforts in order to prevent overlapping and to secure that there should be an equal distribution over the whole area of all the public-spirited and philanthropic efforts which were already made. It was a decentralisation of effort and a concentration of control, giving to the smaller organisations all that additional strength which resulted from united effort. The scheme consisted of the division of the area into districts with responsible officers in each, people who had local knowledge and would take care that abuses would not occur.

Dr. FOX said that the time had come when the consideration of the King should be called to the condition of provincial hospitals, and he proposed an amendment on the subject which the CHAIRMAN ruled out of order.

After some discussion the following was adopted :—

> That this conference has heard with interest of the scheme of the Bedfordshire Hospital Guild as a means of increasing local interest in the county hospital and extending its usefulness by promoting more intelligent efforts for the prevention of disease and for the better after-care of convalescents.

The Prevention of Tuberculosis.

The Rev. W. BLISSARD proposed—

> That tuberculosis should be included among notifiable diseases, with a view to the isolation of such patients in publicly provided hospitals.

Tuberculosis, he said, was the scourge of modern civilisation. Hospital treatment for this disease was quite inadequate Tuberculosis might be looked upon as a condition resulting from all those activities which were building up the wealth and the prosperity of the nation. From this point of view he urged that public provision should be made for the accommodation of tuberculous patients, as the position was far beyond that which could be dealt with by voluntary effort and he made a strong appeal to public conscience and public power. The expense would probably be heavy, but unless some such proposal was carried out there would be a loss of lives which, if saved, would be of the greatest use in building up the national prosperity.

Dr. DAVY moved as an amendment :—

> That the consideration of the propriety of the notification of tuberculosis be postponed, and that the Government be asked to appoint a commission to recommend the best way to deal with tuberculosis.

He said the notification of tuberculosis was a very complicated matter. Dr. H. T. Bulstrode, who had lately published the result of a long inquiry into the subject, had suggested that tuberculosis was dying out and would die out as sanitation improved. He (the speaker) was not at all satisfied, however, to leave things as they were. Roughly speaking, some 60,000 persons died from tuberculosis each year in the United Kingdom. People could not be willing to leave the subject alone when they believed that more than half of that death-rate could be prevented by carefully considered measures of prevention. Such measures should be carefully devised by a body of men who would be influential enough to command the respectful attention of the nation. This question affected every part of our national life and could not be dealt with as if it were a question merely of the notification of the disease. He suggested that a body of influential unbiased men, laymen and medical men, should consider the question, and they could only be called together by a Royal Commission.

The amendment was seconded by Dr. HERON and, being accepted by the Rev. Mr. BLISSARD, was carried unanimously.

Medical Men and Hospital Boards.

Dr. J. FORD ANDERSON proposed :—

> That with the view of securing the cordial support of hospitals by medical practitioners, it is desirable that they should nominate representatives for election to boards of management of hospitals in their respective localities and that such nominations should be carried out by an organised professional body, such as a division of the British Medical Association.

Mr. MANSFIELD, M.P. (General Hospital, Northampton), opposed the proposal which on being put to the vote was lost.

On the proposal of Dr. T. W. GRIFFITH (Leeds) it was declared desirable that temporary accommodation should be provided in hospitals for certain cases of unsoundness of mind for purposes of observation.

The proceedings then concluded.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between March 28th and April 3rd by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscribers of Five Guineas.

Forfarshire Medical Society, per W. E. Foggie, Dundee.
Fylde Medical Society, per Leonard Molloy, Blackpool.
Walter Tate, London.
Sir John Tweedy, London.
W. Wilson, Garndiffaith, near Pontypool.

Subscribers of Two Guineas.

H. Brunton Angus, Newcastle-on-Tyne.
H. C. Bevan, Blaina, Mon.
H. T. Butlin, London.
Evan N. Davies, Pen-y-Graig, Rhondda Valley.
J. Magee Finny, Dublin.
W. C. Humphreys, Swansea.
J. Ernest Lane, London.
Farquhar Macrae, Glasgow.
Sir Malcolm Morris, K.C.V.O., London.
Rodman, Hovenden and Hovenden, London.
Simeon Snell, Sheffield.

Subscribers of One Guinea.

E. H. Addenbrooke, Kidderminster.
Sir W. H. Allchin, London.
W. M. Abbott Anderson, London.
H. R. Andrews, London.
T. W. Bevan, Nantyglo, Mon.
J. E. M. Brown, London.
E. F. Buzzard, London.
Claude Douglas, Leicester.
Clement Dukes, Rugby.
E. B. Ffennells, Hindhead, Essex.
Charles Gibbs, London.
F. L. C. Greaves, Derby.
E. Collier Green, Derby.
W. F. Haslam, Birmingham.
R. W. Haslett, Pontypool.
K. R. Hay, London.
D. de Vere Hunt, Cardiff.
G. H. Hunter, Haughley, Suffolk.
C. A. Lee, Hull.
T. Lettis, Great Yarmouth.
D. V. Lowndes, Surgeon, R.N.
G. H. Mapleton, Goudhurst, Kent.
F. Marsh, Birmingham.
M. W. Manuk, London.
Sir John Moore, Dublin.
S. Moore, Leeds.
S. G. Morris, Mardy, Glam.
A. W. Murray, Liverpool.
J. D. O'Sullivan, Aberbeeg.
Arthur and A. de St. L. Periga New Barnet, Herts.
G. H. Ransome, Bungay, Suffolk.
Alonzo G. Rider, Devonport.
G. J. Robertson, Oldham.
H. P. Rowlands, Towyn, Merioneth.
G. H. E. Shears, Liverpool.
J. Shinlaw, Ferryhill, Co. Durham.
R. Sinclair, Dundee.
James Somer, Exeter.
J. L. Thomas, Brynmawr.
R. S. Thomas, Exmouth, Devon.
Wm. Thomas, Birmingham.
Sir Edgecombe Venning, London.
H. S. Walker, Leeds.
E. C. Warren, Gillingham, Kent.
W. M. Crawford Watson, Harrogate.
G. F. Wolsford, Tiverton.
J. H. Whelan, Cardiff.
W. M. Willis, Nottingham.

Subscribers of Half-a-Guinea.

T. W. H. Garstang, Altrincham.
Hugh Kenshaw, Pudsey.
H. Lucas, Huntingdon.
Colin D. Lindsey, Plymouth.
A. A. Lipscomb, Wrotham, Kent.
W. H. Maidlow, Ilminster.
A. Pain, Durham.
F. S. Penny, Capt. R.A.M.C.
J. R. R. Pollock, Tiverton.
Frank Radcliffe, Oldham.
Gordon Sharp, Leeds.
H. Sandford Smith, Eltham.

Subscribers of Ten Shillings.

James Arthur, Wingate, Durham.
William Fuller, London.

Subscribers of Five Shillings.

G. G. M. Black, Tomintoul, Banffshire.
T. A. Cambridge, London.
Leonard Grant, London.
J. G. Macaskie, Bamburgh, Northumberland.
T. Martin, Bristol.
L. F. Marks, Mumbles.
Henry Stear, Saffron Walden, Essex.

Subscribers of Half-a-Crown.

P. H. D.
A. Greenwood, London.
A. Harris, London.
A. Howie, London.
A. F. Shoyer, London.
Dr. Simpson, London.
H. F. Staunton, London.

becomes incandescent and ignites the mixture prior to compression, with consequent overheating and loss of power. The frequent taking down of the cylinders for removal of this deposit by scraping is a trouble and the new type of Longuemare carburettor cures by the best method—that is, prevention—the avoiding of too rich a mixture. The perfect cooling of a petrol engine is perhaps the greatest feature in a car, as overheating is the bugbear of all cars. It causes excessive expansion of the incoming charge, so a full one is not admitted. In addition, the excessive heat results in premature ignition and so the mixture is exploded before it is compressed, with the consequence that there is loss of power and, furthermore, the lubricant is burnt up and so the piston may seize or a connecting-rod break—all interesting but unpleasant pathological events. The Humber is well guarded against such disasters. An improved honeycomb radiator with a fan at the back is fitted and there is a positively driven rotary pump of ample proportions fitted with a filter and placed so that it can be easily dismantled for cleaning. I took the car up some really bad hills, ascents to which Shooter's Hill, Netherhall Gardens, and even River Hill at Sevenoaks are nothing, and I must say that it mounted them all easily and, what is more, without the engine showing any signs of "heating."

Probably more stops are due to ignition functional disorders than to any other, and though I know that such an authority as Mr. S. F. Edge does not consider two ignition systems desirable, still as it is not always convenient for a medical man to stop on the road if an electric fault occurs I strongly advise my professional brethren, if possible, to have two separate means of exploding the mixture. The Humber can be fitted both with high-tension magneto and high-tension coil and accumulator, so in the, I admit, unlikely instance of one failing, instead of having to stop, the other can be switched on, which I am sure is an advantage. Of course, the accumulators must be kept charged and the tremblers on the coil adjusted, and so it is as well to make a rule to start the engine up on the coil and accumulators and afterwards to turn on the magneto, and this too makes the starting much more easy and in addition insures that the accumulators are kept charged. The drive is by the now popular cardan shaft and "live" axle and perfect running is obtained by the driving shafts and bevel pinions being mounted on ball bearings, ball thrust bearings being also fitted, and as a result of the firm's long experience in the bicycle trade their knowledge of ball bearings is probably unique and their car bearings have obtained a similar fame to that of their cycle bearings. A leather-faced cone clutch is provided, but in their 30-h.p. metallic discs running in an oil bath are fitted. Perhaps on high power cars the multiple disc may be desirable, but I have always found a leather-faced one satisfactory, provided that it receives an occasional dose of collan oil, and with care the leather should last for many a year, and in addition if it has to be replaced it is easily done. The side brakes are of wood fibre and spring steel working on a flanged brake drum of large diameter and width, and the foot brake is metal to metal, the drum being between the rear gear box bearing and universal joint. The adjustment is by a winged nut which can be turned by hand. All are operated by rods, certainly an improvement on the old-fashioned cable. They are most powerful, and I gave them a good test on a really bad hill and found either of them capable of stopping and holding the car on a gradient of 1 in 6 in both directions. I understand that this car is sold fitted with a Cape-cart hood at about £250, and at this price it is well worthy of the consideration of the profession. It certainly rides most easily, which is, I believe, greatly due to the transverse rear spring.

A matter that is likely to affect all motorists is the proposal of the Royal Commission regarding the future taxation of cars. As Dr. H. E. B. Bruce-Porter, who is the honorary secretary of the committee of medical men using motor-cars, remarks, it is perhaps too much to expect the Government here to treat medical men as they do in Germany, where it is accepted that as the profession do so much gratuitously the medical man should receive some recognition and so his car is exempt from taxation. Still, it does seem but fair to put forward the suggestion that even though a medical man may use his car for a short holiday, still he should be merely taxed at trade rate. I am sure that the public as well as the profession would welcome this acceptance of the work which the profession do, and do without even thought of a fee. In hilly districts a medical man must have a powerful machine, and the proposal is that if it weighs over 15 cwt. he should pay £5 5*s*., whereas under that weight it is but £3 3*s*. It certainly seems hardly fair to have to pay £2 2*s*. a year extra because the neighbourhood is hilly. The motor is not only the pastime of the rich, as those who motor about can see; there are many motorists of moderate means and a heavy tax is bound to decrease the number of cars kept by this class, and surely this will affect what is now becoming, if it has not already become, a great industry—the manufacture of cars. Let us trust that the Government will give this matter deep consideration before it accepts the proposal of the Royal Commission. Mr. Leveson-Gower has propounded an original scheme as a basis for taxation. He quite correctly argues that the motorist should pay according to the mileage he covers, and, as he says, the outer covers of the tyre are to a great extent an index to the distance covered, so he suggests that the tax should be collected from the tyre maker or importer and each tyre bear a Government stamp. It will be a cheap tax to collect and if it becomes law I rather think that I shall get my tyres retreaded more often than I do at present, and I believe my fees for visiting in a road that contains unrolled stones will increase. Perhaps this tax would help in reducing excessive speed, for road racing does more than anything else to wear out tyres, so it will come rather hard on professional men receiving many urgent calls.

Everyone is now fond of talking of the individual known as "the motorist of moderate means," and I take it that the average medical motorist may well claim to come under this category. Tyre bills have always been a formidable item in the cost and upkeep of a car, and it will be welcome news to all that tyre makers are now reducing their prices. The Continental Tyre and Rubber Company, Limited, who at their Hanover works alone employ over 5000 hands, are, as a result of the reduction in the price of raw material and their great facilities for manufacture, making substantial reductions not only in the ordinary motor tyres but also in their armoured studded non-skid type. The advantage of this is that not only may tyres of a larger size than usual be fitted on new cars at no increased cost over that which obtained previously, but also non-skids on the rear wheels. Speaking from experience, I can say that a larger-sized tyre, especially on the driving wheels, is a great economy. Many cars are fitted with the 810 mm. by 90 mm., but with the present reduction 810 mm. by 100 mm. can be substituted, especially as they fit the same rims. It is most surely always better to use tyres of a stronger pattern than absolutely necessary; they last much longer and are not so liable to cut. The use of non-skids, if merely as a sort of moral comfort, is an advantage; the knowledge that skidding is not likely to disturb the harmony of a drive does give greater confidence, especially if the owner is his own driver. I recently had an example of this "psychological effect." A friend in wet skiddy weather drove me from the suburbs of London to the West-end in his car and on our arrival remarked: "I should not have been able to do this without non-skids," when, to his astonishment, he discovered that the non-skids had, unknown to him, been taken off by his man and that he had driven on ordinary round treads. Still, non-skids in traffic are an advantage, and the Continental Red-Black 1908 pattern, in addition to absolutely preventing skidding, greatly reduces the chance of puncture as they are practically covered with steel. The studs are fixed in the tyre without the aid of leather by patent discs, immediately under the head of the rivets, and if only the tyre is kept well pumped up it is impossible for the studs to become loose or torn out; the great thing is to keep the tyre fully inflated.

Some unconsidered points in the wear of tyres have recently been brought out by Mr. Mervyn O'Gorman in a paper read by him before the members of the Royal Automobile Club entitled "A Number of Things and their Effect on Tyres." Undoubtedly, he has shown that both in chain-driven and, to a certain extent, in shaft-driven cars the distance or torque rods do not keep the drive constant when the car moves up and down on its springs, and thus there is an irregular drive to the road wheels and consequent rub and wear of tyres. In some cars, such as the excellent little Humber, the push is taken by the springs, radius rods being done away with, but in these the flattening of the springs gives a further movement backwards to the axle and this movement is additive.

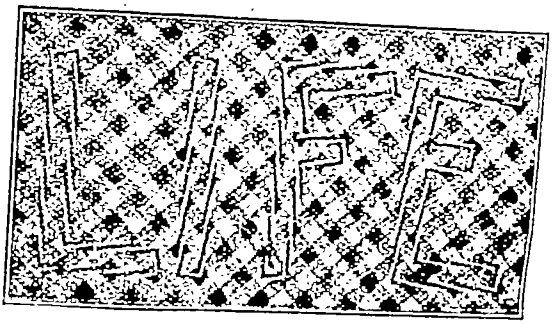
outbreak had taken place. The facts, apparently beyond dispute, that the water had not been in a condition of purity, and that the widow, who went into the witness-box to say so, had herself complained with regard to it, no doubt were accorded serious consideration by the jury who awarded her £650 damages, for which sum judgment was entered by Mr. Justice Grantham, a stay of execution being refused.

The Pistol Again.

The still frequent occurrence of accidents and intentional injuries inflicted by pistols, which evidently have been acquired by their possessors without any difficulty, points to the insufficiency of the late Act of Parliament regulating the sale of such weapons, so far as the protection of the public is concerned. A few weeks ago the suicide of a young lady in a train showed that she was in the habit of practising shooting with a revolver and in her case the existing statute would naturally have been of little avail and perhaps no other one likely to be passed would have been much more effectual. More recently, however, another woman has selected the same manner of committing suicide and in her case the enforcement of the Act might have given her time for reflection and might have deterred her from her purpose. It was not, however, enforced, with the result that Mr. A. H. Watson, a gun-maker in Bond-street, and his salesman were summoned before Mr. Denman recently at Marlborough-street police court. At the hearing it was shown that a lady known as Margaret Leighton or Alcott bought the pistol at 3 o'clock in the afternoon and on the same evening shot herself with it in a railway carriage at South Kensington. She had paid for the weapon £3 7*s.* 6*d.* and had obtained it without being obliged to produce a licence to carry firearms as a preliminary condition, by means of an ingenious tale that she intended it as a present for her daughter who was going to America. The salesman, apparently desiring to save his customer 10*s.*, allowed her to take away the weapon and as a result of the transaction each defendant had to pay a fine of £3 with 2*s.* costs. They had failed to insist upon such precautions as the law at present enjoins, but it can hardly be contended that these would necessarily have prevented the acquisition of a pistol by a person able and willing to pay £3 7*s.* 6*d.* for it. More stringent regulations might render the purchase or possession of a revolver illegal for any civilian unable to show that he required it for some lawful purpose, and the trade which would be diminished thereby can hardly be regarded as one of importance or as one useful to the community.

A NEW VISUAL ILLUSION.[1]

VISUAL illusions are always interesting and this pamphlet with its nine illustrative plates describes a new form of deception in a very lucid manner. Dr. Fraser states that: "In all the hitherto published visual illusions of direction, with the exception of the chequer-board or Münsterberg illusion, the illusory lines or bands are definitely continuous, uninterrupted in character, of black or of white, on a contrasting background. In the illusion of direction here described each illusory band consists of a series of visibly discrete similar parts, all inclined at the same small angle to the line of direction of the series to which they belong. Such visibly discrete similar parts may be conveniently termed 'units of direction.' Where the illusory band consists of alternating black and white 'units of direction,' it may be conveniently regarded as representing a cord consisting of two strands, black and white, twisted together." This arrangement he refers to in the subsequent descriptions of the illusions as the "twisted cord." A twisted cord laid upon a grey or coloured background of intermediate luminosity will, he says, apparently deviate from its actual line of direction at an inclination corresponding in trend (but at a smaller angular degree) to the inclination of the units of direction. This illusion is much increased in degree when the twisted cord is laid upon a chequer-work background of squares of white, black, and an intermediately luminous grey in such a way that it bisects diagonally each member of a series of black and white squares, its black and white units bisecting respectively white and black squares (their contrasts) at a small angle with the diagonal line of the square. Dr. Fraser's description continues as follows: "In such a figure each unit of direction is now, in effect, lengthened by the addition of a triangular area of the same luminosity at each of its ends. These triangular areas are derived or borrowed from the neighbouring squares belonging to the series on which the twisted cord lies, and they lie on opposite sides of the twisted cord." The reader will find that on holding the pages containing the illustrated figures on a level with the eyes so as to foreshorten the characters Dr. Fraser's explanation becomes at once comprehensible. The "units of direction" then remind us of horse-nails but with a head on each end on opposite sides placed slantwise to form the outlines of the letters forming the word LIFE. If one of the examples is looked at in this manner the apparent sinuosity of outline disappears and the convergence and divergence of other examples are greatly modified. To see how great this modification is, it is only necessary to print on a piece of tissue paper the word Life in simple straight characters of the same size as the apparently crooked letters. When the rectangular word on the tissue paper is laid upon the "crooked" word as printed above the superimposition will be found almost exact. The paper well deserves study by those interested in the subject.



THE FIRST INTERNATIONAL FIRST-AID AND LIFE-SAVING CONGRESS.

THE First International First-Aid and Life-Saving Congress which will be held at Frankfort-on-Main during Whitsun week of the present year, should prove to be of great interest, especially as the ever-increasing use of machinery and the altered conditions of the means of transit demand in the interests of the public the fullest consideration of the questions with which the Congress will deal.

As will be seen from the programme, many of the matters to be discussed have already received special attention in the United Kingdom, while the exhibition which will be held in connexion with the Congress will afford an opportunity for this country to occupy a fitting position in a movement of great importance.

The Congress will open on June 9th under the presidency of His Excellency Dr. Count von Posadowsky when there will be a reception of delegates in the Rathaus followed by a supper in the Rathskeller. On June 10th the Congress will meet in "Jügel Haus" and later in the day a banquet will be held in Frankfurter Hof. On June 11th the sectional meetings will be followed by a general meeting and a visit to the opera in the evening. On June 12th the proceedings of the Congress will be continued and a garden party will be held in the evening in the Palmengarten, and on June 13th, after the final meeting of the Congress, a visit will be made to the Hôchst Farbwerke and supper will be given at the Kurhaus at Homburg. The provisional programme also announces that the Congress will be divided into ten sections dealing respectively with medical first-aid in cases of accident, instruction of non-professionals in first-aid, ambulance work in towns, ambulance work in the country and in industrial and small communal centres, ambulance work on land (railway, automobile, &c.), ambulance work at sea and on inland and coast waters, ambulance work in mines and similar places, ambulance decima consurgit inde. Si autem quantum ad intrinseca dupliciter aut *quo* ad theoricam seu practicam et reliqua. Ideo si quidem sufficienciae modus ceteris posset adaptari quaesitis, ut quorundam est studium. Sed quia potius *curiositatem cum prolixitate adducit quam* utilitatem in his idque deinceps omittatur quaesitis.

---

[1] A New Visual Illusion of Direction. By James Fraser, M.B., C.M. Aberd., Deputy Medical Superintendent, Central London Sick Asylum. Reprint from the Journal of Psychology, vol. ii., part 3, January, 1908.

We are indebted to the Rev. H. Lucas, S.J., of Stonyhurst College, for assistance in the following paraphrase. The meaning of the text is in one place at least obscure:—

> The object of the science of medicine is the human body, as capable of cure. Like the other branches of learning, it may be considered from two points of view—namely, the intrinsic or the extrinsic. Of these two, the former may have reference severally to the formal, the material, the efficient, and the final cause. The formal cause—i.e., the quality of "curableness," if considered generally, may be regarded either (1) in relation to the perfection itself, i.e., *health*, and so we arrive at the first division, the "prima differentiarum," of the subject, or (2) in relation to the way in which the perfection is to be attained (*modus*). But if taken more specially it may be regarded (3) in its entirety, or (4) as to its intellectual, or (5) its affective side. (This passage is very obscure.) With regard to the material cause, the body (?), this may be regarded either (6) as an object of diagnosis or the knowledge of its present state or defect, or (9) with reference to the normal or permanent state to which it is to be brought. The efficient cause of health is (7) the medical man (*artifex*), and (8) his drugs, rules for their use, &c. (*ars*). The final cause is (10) health.

It will be noted that Petrus skips from No. 6 to No. 9 for no apparent reason. The "four causes" above mentioned are the Aristotelian causes. In the Middle Ages a great deal of ingenuity was expended on treating all manner of subjects in the light of this fourfold causality. Petrus, however, seems to have had an idea that arguments of this kind were not altogether commendable, for it will be noted that the passage which we have quoted concludes, "But as this discussion tends rather to vain and wordy disputation than to any useful purpose, let us here cease from our inquiry."—ED. L.

THE UNITED HOSPITALS CONFERENCE.

THE third United Kingdom Hospitals Conference was held on April 1st and 2nd at University College, Gower-street, London, W.C., under the chairmanship of Mr. CHARLES LUPTON, chairman of the General Infirmary, Leeds. There was a large representative attendance.

Eligibility for Hospital Treatment.

On the opening day, April 1st, Mr. H. C. GOSNELL (City of London Lying-in Hospital) in discussing this question argued that poverty or want of means should not be considered the only test in determining a patient's inability to pay for hospital treatment. Among the middle classes, and particularly the lower middle classes, there were a large number of persons who wore black coats and who showed no external evidence of poverty, yet who were equally as deserving of the benefits of charitable institutions as the labouring classes. As an amendment to the proposal discussed at the last conference—namely, "That inability to pay should be the consideration for the admission of all patients," he moved—

> That in determining the question of the suitability of patients for admission into hospitals, *particularly* with reference to their inability to pay for adequate treatment, poverty or want of means should not be deemed the only test of the patient's *eligibility* for admission, but persons should be deemed eligible whether they belong to what are termed the working or industrial classes or not, if, owing to their obligations being disproportionate to their means, they are unable to pay for the professional services of a medical attendant.

Mr. R. B. DOBSON (Brighton) seconded the amendment which on being put to the vote was lost. The original proposal discussed at the last conference was therefore endorsed by the present conference.

Gratuitous Treatment in Compensation Cases.

Mr. HARRY JOHNSON (Leicester Infirmary) moved:—

> That it is desirable to supply gratuitous hospital treatment to those who are provided for by the Workmen's Compensation Act.

He pointed out that it would be wrong to deprive persons receiving benefit under the Workmen's Compensation Act, which could not exceed £1 per week, of the help which they would otherwise receive. The best way to obtain payment from the working classes was to ask them to contribute during health.

Dr. J. A. MACDONALD (Taunton) urged that the hospital almoner should deal with cases on their merits. He said there were instances in which men who came under the Act received substantial sums weekly from friendly societies.

Mr. J. H. SHAW (Southport) said that the rule of making a patient able to pay or the person whose negligence caused the accident refund the cost of the treatment had, at any rate in one instance, especially in regard to motor-car accidents, worked admirably.

On the suggestion of Dr. FRANK FOWLER (*Bournemouth*) the words "whom the hospital board shall consider unable to pay for medical attendance" were added to the original proposal and the motion as amended was adopted.

Payment for Food and Medicine.

Mr. SYDNEY HOLLAND (chairman of the London Hospital) moved:—

> That where they can afford to do so hospital patients ought to be asked to pay for the food, medicines, and bandages supplied to them.

All hospitals, he said, especially London hospitals, were in a serious financial position. Hospital authorities were making a great mistake in not asking patients whether they could afford to contribute towards their treatment. It was economically unsound to give everything to everybody for nothing, whether *they could afford to* pay or not. At the London Hospital last year 157,000 persons paid sums representing £2000 without any pressure being put upon them. The charitable work of hospitals ought to be restricted to providing for the sick poor that help which they could not afford to pay for themselves.

Mr. W. CARNT (Manchester Royal Infirmary) said a large proportion of the in-patients at his institution paid sums ranging from 2*s*. 6*d*. to 7*s*. 6*d*. per week. By this means £1000 or £1200 a year were added to the income of the Royal Infirmary.

Mr. R. CAPES (chairman of the South London Hospitals Committee) said if the hospital authorities would reduce the number of out-patients by sending trivial cases to the general practitioner they would have enough money for their other requirements.

Dr. HENRY DAVY (President of the British Medical Association) opposed the proposition and said the question of payment raised that of the whole charitable hospital *system* of the country. He preferred the German system of municipal hospitals.

Dr. G. A. HERON (City of London Hospital for Diseases of the Chest) said the sooner reliance on State support of hospitals came the better. This system of payment, small though it was, *struck at the root* of all true charity. There was the greatest difficulty in *separating those* who were necessitous from those who were not. He knew of people in receipt of £800 per annum who habitually used the outpatient department of free hospitals.

Mr. R. G. PATERSON (Glasgow Eye Infirmary) said the working class who supported that institution looked upon treatment as a right and to ask for payment would shut off a large portion of their income.

Dr. E. L. FOX (Plymouth) supported the proposal.

Mr. SYDNEY HOLLAND said his hospital had never lost a farthing support in *consequence of making a charge* nor had the system either increased or decreased the number of patients. The *class that the hospitals* existed for was the class just above the necessitous poor. The clerk in receipt of £200 a year was a proper person for help but he ought to be asked to pay for the food, medicine, and bandages supplied to him.

The proposition was carried.

Investigation of Cases.

Lieutenant-Colonel MONTEFIORE (Charity Organisation Society) moved:—

> That in the opinion of this *conference* the appointment of trained hospital almoners constitutes one of the best methods for checking the misuse of hospitals and for rendering more effective the economic value of an out-patient department.

This on being seconded was carried.

Payment by Patients at Cottage Hospitals.

On the second and concluding day, April 2nd, the proceedings commenced with the adoption of a proposition by Colonel J. G. CURTIS (Deal and Walmer Victoria Hospital) to the effect that some definite steps should be taken to ascertain the ability or the contrary of each patient at a cottage hospital to pay for his or her maintenance.

Hospital Accounts.

On the motion of Dr. FOX the committee was instructed to consider how the uniform system of accounts recommended importance are the measures for preventing diffusion from actually infected to healthy localities, and last of all come the means for combating each local outbreak. It is evident that considerable difficulties will be experienced in attaining the primary object due to the impossibility of discovering definitely every endemic centre, so that all potential ones must be attacked, involving a large number of localities; again, they must be attacked before the infection becomes active. Thus a very large staff is necessary, and as the medical staff can never be increased sufficiently to meet requirements, the necessary measures must be undertaken by the people themselves. Amongst the preventive measures employed we see that rail and road inspection was carried out, whilst there were surveillance over arrivals, isolation, and segregation. The right of refusal to allow persons from infected areas to enter healthy localities was hardly ever enforced owing to the social customs and binding obligations of hospitality of the people. In the face of an epidemic evacuation is considered to be the best and most effective measure but it is rarely carried out by the people effectively; whilst the Hindus will practise it the Mahomedans are taught that it is against their religion and consequently seldom adopt it. Disinfection is rarely effective from the fact that information is but seldom received sufficiently early to allow of its successful application. Insecticides are being tried but the chief reliance is placed on heat. Without doubt inoculation is one of the best and most effective methods of prevention but the people are loth to undergo the operation and its slight inconvenience unless danger is actually present. Owing to the comparative mildness of the epidemic of 1905-06 the operation was less done than in the previous year; 27,924 inoculations in all were performed.

The destruction of rats was held to be very important. The general opinion was pronounced in its favour and recrudescences were held to have been prevented or delayed and also the epidemic to have been mitigated, even when the measure was applied after infection. Captain G. I. Davys, I.M.S., brings forward some remarkable evidence in its favour, for where it was thoroughly carried out no cases of plague occurred; where nothing was attempted severe epidemics followed recrudescence. A good example of this is afforded by the Amritsar district, in the very heart of the infected area, where no recrudescence occurred, all the cases being due to importation. The difficulties in the successful application of this method consist in the innate prejudices of the people, as certain sections object to the taking of life, or in the ignorance and suspicion engendered by any new measure. Thus, with regard to the former, the whole town of Mukerias was baited for these animals excepting two clumps of houses inhabited by Jains; in these only did recrudescence start. To be effective, however, the people themselves must be the active agents, and to insure this the active coöperation of their natural leaders is being enlisted. With regard to the actual medical treatment, everything is done to give assistance to all who wish it but not very much can be done in the way of systematic treatment, as the medical staff are constantly on the move.

North-West Frontier Province.

In the North-West Frontier Province 44 cases of plague occurred in 1906—namely, 41 in the Hazara district, 2 in Peshawar, and 1 in Dera Ismail Khan. Of these 40 proved fatal in Hazara and 1 in Peshawar. A man suffering from plague went from Rawal Pindi and imported the disease into the Hazara district. He died at the village of Ghazi and his relatives, occupying the same house, contracted the disease which spread to three neighbouring villages.

United Provinces of Oudh and Agra.

The returns from the United Provinces of Oudh and Agra show a diminution of mortality for 1906, there being 69,660 deaths recorded from plague during the year, contrasted with 383,862 in 1905, the death-rate being 1·46 and 8·05 respectively. The highest mortality was in March and the lowest in July. The total number of persons reported to have been inoculated with anti-plague vaccine was only 1846, against 6411 in 1905. No persons are reported to have died from plague after inoculation.

Eastern Bengal and Assam.

Coming now to the province of Eastern Bengal and Assam there were several outbreaks of the disease in 1906. For instance, in the month of March there was an outbreak of a pneumonic character in the Pabna district, said to have been imported from Calcutta. A patient died on the voyage up the Brahmaputra; his body was carried home by two friends who themselves contracted the disease and became the centre of infection. Again, in June there were two other outbreaks, both pneumonic and both imported from Calcutta. In these three outbreaks there were 82 cases with 74 deaths. From an inquiry into the history of plague in this province since 1898 there have been seven distinct epidemics, the original cases of which were all imported from Calcutta or its neighbourhood. Nearly all were pneumonic in character with a history of direct infection of the healthy from the sick in every case; there was never any history of distribution by rats or any connexion with grain. There was, however, one exception—namely, in the Dibrugarh outbreak which was bubonic in character and appears to have been connected with granaries and rats and not to have been imported by human agency.

Bengal.

Respecting the province of Bengal, the mortality, which had been steadily increasing of late years, showed a very satisfactory reduction, there being 59,619 deaths in 1906 as against 126,084 and 75,433 during the two preceding years. Thus the number of victims has dropped to less than half of that of 1905. The diseases affected the females more than the males and the rural areas more than the towns. With respect to its seasonal prevalence, there was great intensity of the disease during the first few months of the year, due to the coolness and excessive rains. With the onset of the hot weather there was a sudden drop. With regard to the measures employed for combating the disease, antiplague inoculations to the number of 1777 were performed as against 1544 in the preceding year. No cases of, or deaths from, plague occurred amongst the inoculated. Chemical disinfection was carried out in special cases where it was asked for, and also in several municipal areas where it could be supervised. Disinfection by heat and evacuation of infected houses have become very popular and are generally resorted to by the rural people. In Saran we are glad to see that general instructions on plague and its prevention have been drawn up and distributed broadcast over the district, the method of disinfection being minutely described and evacuation being recommended. At Bhagalpur the disinfection was carried out by the spraying of the insides of the infected houses with kerosene oil by means of the "Success Knapsack Sprayer," which was followed by signal success. Lastly, rat-killing is gradually becoming popular. In Jagdespur, where the work was done systematically, the town enjoyed a complete immunity from the disease, whilst recrudescences occurred with considerable severity in adjoining thanas and all the other towns in the district except Sasaram.

Central Provinces and Berar.

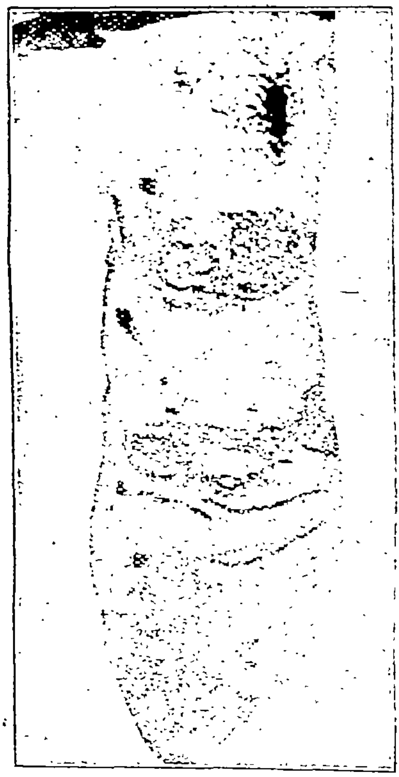
In the Notes on the Annual Statements of the Government Charitable Dispensaries in the Central Provinces and Berar for 1906 we find an important note from the manager of the Empress Mills, Nagpur, on the results of the inoculation of the employees during the outbreak of plague at Nagpur in 1905-06 by Mr. Bezongi Dadabhoy, the manager. This gentleman remarks that during the plague season 1119 persons were inoculated, of whom five were reported dead, but that two at least of these cases must have had the germs of plague before they were inoculated. Amongst the uninoculated, numbering 2665, there were 179 deaths reported. He had invariably found inoculation with Haffkine's vaccine to have a very beneficial effect in reducing the severity of, and mortality from, plague, the only mishap being a few cases of abscesses and consequent illness; the last series of inoculations, however, showed a vast improvement and the results were remarkably good.

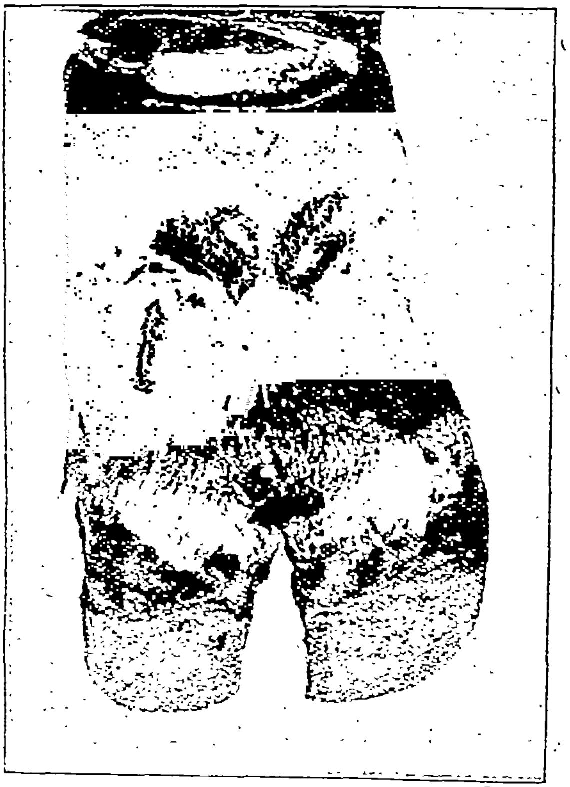
Central Midwives Board.—Special meetings of the Central Midwives Board were held on March 26th and 27th at Caxton House, Westminster, Dr. F. H. Champneys being in the chair. The Board considered various charges—such as uncleanliness, drunkenness, and omission to send for medical assistance in the statutory manner—against midwives, the result being that the names of 18 women were to be struck off the roll. Seven midwives were censured and two were cautioned after charges alleged against them had been considered. The application of an ex-midwife for the restoration of her name to the roll (removed by the Board Dec. 12th, 1907) was refused.

A TYPICAL CASE OF FOOT AND MOUTH DISEASE:

INTERESTING ILLUSTRATIONS.

WE are indebted to Mr. T. R. D. Carruthers, of St. Vincent-street, Edinburgh, for the interesting photographs which we reproduce below. The infected cow was attacked during the recent outbreak of this disease in Edinburgh, and the dark markings on the tongue and at the division of the hoof indicate well the site and appearance of the disease. The photographs were from specimens supplied by Professor J. R. U. Dewar, Principal of the Royal (Dick) Veterinary College, Edinburgh.





MEDICINE AND THE LAW.

Brown v. Butler: Negligence in Supplying Impure Water.

AN action, the hearing of which lasted for several days, ended recently in a verdict awarding damages to a widow, Mrs. Margaret Sophy Brown, in respect of the death of her husband, formerly farm bailiff at the Three Counties Asylum, Arlesey, Bedfordshire. The defendant was sued as the clerk to the committee of visitors of the asylum and the claim was based upon the alleged negligence of the defendant in supplying impure water for the consumption of the deceased with the result that he contracted enteric fever and died. There was a further allegation of negligence with regard to the medical attendance supplied to him under his contract of service, but this portion of the claim was abandoned after the evidence had shown that it could not be sustained. The evidence proved that the water supplied to the inmates of the asylum and to the cottage of the deceased, which was within the grounds belonging to the asylum, was derived from two wells and that it went through a softening process, being afterwards pumped up to water towers whence it reached the consumers. It was part of the widow's case that drains conveying sewage matter from the asylum to a sewage farm passed near one of the wells and were found to be in a very bad state after the death of her husband had taken place, and apparently Sir Thomas Stevenson (who was called for the defence) had found the bacillus coli present in the water, and Mr. G. F. Deacon, C.E. (also a witness for the defence), had attributed the enteric fever to the condition of the water-supply in a report made by him upon the subject. There was conflicting evidence as to the nature and extent of the complaints made by the Browns with regard to the water-supply and as to admissions by officials of the asylum before his death with regard to its defects, but the fact that the plaintiff had been alarmed at the appearance of the water was established, although it was not admitted on behalf of the defence that its turbid condition, to which she called attention, was caused by the presence in it of dangerous matter or was connected with her husband's illness. For the defence it was contended that the deceased had visited Yarmouth for a few days' holiday, returning on July 25th, 1906, and that his illness, of which he first complained on August 22nd and from which he died on Oct. 1st, was, or might have been, contracted there; that no trace of enteric fever contamination was traceable in the water, and that if the water had been contaminated a general outbreak in the asylum would have taken place inevitably and not merely a single case outside it. There was also evidence that cases of enteric fever had occurred in the neighbourhood, this being given presumably in order to show that, should the jury not ascribe the disease which affected the deceased to his visit to Yarmouth, there were still sources other than the water from which it could have been derived. Sir Thomas Stevenson, in his evidence, supported the view that a general outbreak should have taken place had the water been to blame, and explained that his report as to the undesirable condition of the water was due to the presence of the bacillus coli only. He also spoke of Yarmouth as a place in which the deceased would be likely to contract enteric fever. Mr. Deacon explained that a passage in a report made by him in which he said that "I think that there is no room to doubt that the outbreak was caused by the water" was based upon a mistaken belief that a general that "the borough with its sewers all practically unventilated is in a deplorable, not to say dangerous, condition." The town council is, it appears, ever ready to maintain house drainage in an efficient state but "no attempt is made by the sanitary committee to put their own system of drainage in order." This is very wholesome and candid criticism on the part of Mr. H. W. Newton, the medical officer of health, and we trust that it may have the desired effect. At any rate, the responsible officer cannot be accused of neglect to draw attention to the facts. As regards the disposal of house refuse, the medical officer of health can "report nothing favourable," and it seems that the authority is a nuisance creating as well as a nuisance abating body. A refuse destructor is, it is thought, the best remedy. The water-supply of the borough, 17·7 gallons per head, is, the medical officer of health thinks, inadequate, more especially as two of the sources of supply show definite signs of steadily decreasing in amount. The borough should, in his view, be furnished with an adequate and a constant supply. At present the greater portion of the town is on an intermittent supply.

Buckingham Rural District.—Dr. P. L. Benson in deploring the high infantile mortality which still obtains in the country generally thinks that if anything approaching the same mortality (about 15 per cent. of the children born) obtained amongst animals on a farm the farmer would have to relinquish breeding operations. Dr. Benson states that the mortality among chickens is 2 per cent.; pigs and cows, 4 per cent.; and horses, 8 per cent.; but it is not quite clear from the context whether these rates apply to the whole of the first year of life or only to the first few weeks. Dr. Benson is evidently an advocate of milk depôts and in connexion with this subject he refers to some experiments recently carried out under the direction of Mr. Nathan Strauss in Heidelberg, in which five guinea-pigs were inoculated with tuberculous milk in a raw state and five others with such milk after it had been pasteurised. The first five animals shortly developed tuberculosis but the latter remained free from the disease. The death-rate from pulmonary tuberculosis in this rural district for 1907 was 0·65 per 1000, as against a *nil* return for 1906.

St. Anne's-on-the-Sea Urban District.—Dr. Frederick Booth proposes to deal with phthisical patients in a somewhat drastic fashion. He would have them treated in the same manner as patients suffering from acutely infectious diseases like typhus fever or small-pox and isolated for the safety of the public. We wonder what the phthisical breadwinners, with, perhaps, very many years of useful work before them, would say to a proposal on the part of the medical officer of health to separate them from their families for the remainder of their lives or until they were cured. Provision for the families would presumably have to be made out of the local rates. We should have thought that in the vast majority of cases the provision of a separate bedroom or a course of instruction in a sanatorium or isolation hospital or by means of visits from a trained official would suffice. The St. Anne's report makes apparently no differentiation between "open" and "closed" cases of pulmonary tuberculosis. We are afraid that if Dr. Booth endeavoured to enforce his views he would find patients very unwilling to have their malady recognised and hence the opportunities of securing early cases for sanatorium treatment would be few.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8574 births and 5222 deaths were registered during the week ending April 4th. The mean annual rate of mortality in these towns, which had been equal to 16·9 and 17·4 per 1000 in the two preceding weeks, declined again to 16·8 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 18·0 per 1000; the mean rate in London during the same period did not exceed 17·6. The lowest annual death-rates in the 76 towns last week were 9·1 in Leyton, 9·4 in Grimsby, 10·3 in York, and 11·1 in Wigan and in Blackburn; the rates in the other towns ranged upwards to 24·7 in Ipswich, 25·5 in Stockton, 26·1 in Burton-on-Trent, and 26·3 in Merthyr Tydfil. The rate of mortality in London last week did not exceed 16·6 per 1000. The 5222 deaths in the 76 towns last week showed a decline of 182 from the number returned in the previous week, and included 445 which were referred to the principal epidemic diseases, against 410 and 486 in the two preceding weeks; of these, 204 resulted from whooping-cough, 110 from measles, 48 from diphtheria, 41 from diarrhœa, 24 from scarlet fever, and 18 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·4 per 1000, against 1·3 and 1·6 in the two preceding weeks; the rate from the same diseases in London was also equal to 1·4. No death from any of these epidemic diseases was registered last week in Blackburn, Huddersfield, Wigan, Grimsby, or in three other smaller towns; the annual death-rates from these diseases ranged upwards, however, to 3·8 in Hanley, 3·9 in Birkenhead, 4·1 in Newport (Mon.), and 5·9 in Stockton-on-Tees. The fatal cases of whooping-cough in the 76 towns, which had been 134, 152, and 203 in the three preceding weeks, further rose to 204 in the week under notice; the highest death-rates from this disease last week in these towns were 2·2 in Birkenhead, 2·3 in Handsworth, 3·0 in Sunderland, and 4·1 in Newport (Mon.). The 110 deaths from measles showed, however, a decrease of 31 from the number in the previous week; they caused death-rates, however, equal to 1·7 in Croydon, 2·3 in Hanley, 2·5 in Burnley, and 4·9 in Stockton-on-Tees. The deaths referred to diphtheria, which had ranged from 66 to 52 in the four previous weeks, further declined last week to 48, but caused a death-rate equal to 1·9 in Tynemouth. The 41 deaths attributed to diarrhœa exceeded the numbers in recent weeks; and the four fatal cases in Warrington were equal to an annual rate of 2·9. The 24 deaths from scarlet fever showed a decline from the numbers in recent weeks, but included four in Liverpool, three in Birmingham, and two in Leicester. 18 deaths were referred to "fever," against 16 in each of the two preceding weeks, and included three in London, and two both in Preston and in Bradford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 17 preceding weeks from 5591 to 3229, had further fallen to 3121 on April 4th; 315 new cases were admitted to these hospitals during the week under notice, against 378 and 355 in the two preceding weeks. One case of small-pox was under treatment in the Metropolitan Asylums Hospitals during the week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 317, 320, and 349 in the three previous weeks, further rose to 351 in the week under notice, and exceeded by 19 the corrected average number in the corresponding week of the five years 1903–07. The deaths directly referred to influenza in London were 64 last week and were seven below the number in the previous week. The causes of 45, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified last week in Leeds, Bristol, West Ham, Bradford, Hull, and also in 46 other smaller towns; six uncertified causes of deaths were, however, registered in Birmingham, seven in Liverpool, and four in Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 18·5 and 19·4 per 1000 in the two preceding weeks, further rose to 19·7 the week ending April 4th, and exceeded by 2·9 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rates last week ranged from 13·9 and 17·1 in Paisley and Edinburgh, to 21·0 in Dundee and 21·8 in Glasgow. The 694 deaths in these eight towns showed a further increase of 11 upon the numbers returned in the two preceding weeks, and included 97 which were referred to the principal epidemic diseases, against 84 and 114 in the two previous weeks; of these, 35 resulted from measles, 24 from whooping-cough, 20 from diarrhœa, seven from "fever," six from scarlet fever, and five from diphtheria, but not one from small-pox. These 97 deaths were equal to an annual rate of 2·8 per 1000, against just double the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 37 and work by fire brigades, ambulance work on mountains, and ambulance work and sport.

The English committee for the United Kingdom, of which the Duke of Marlborough, K.G., is president, will consist of Sir John Furley, C.B., vice-chairman of St. John Ambulance Association (chairman); Lieutenant-Colonel H. J. Barnes, secretary of St. John Ambulance Association; Dr. W. Collingridge, medical officer of health of the City of London; Mr. Horace S. Folker, vice-president of the National Fire Brigades Union; Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C.; Mr. G. H. Makins, C.B., surgeon to St. Thomas's Hospital; Commander St. Vincent Napean, M.V.O., R.N., chief inspector of lifeboats; Mr. E. O. Sachs, F.R.S.E., chairman of the British Fire Prevention Committee; Mr. S. Osborn, F.R.C.S. (honorary secretary); and Mr. A. M. Oppenheimer (assistant honorary secretary).

A traffic committee has been formed at Frankfort for the purpose of facilitating travelling arrangements and housing accommodation for members of the Congress.

The exhibition of appliances connected with first-aid and life-saving will be opened on June 6th and will be continued during the whole week of the Congress. Inquiries respecting this department of the Congress should be addressed to the exhibition committee, Bethmann Strasse 3, Frankfort o/M.

Particulars regarding the arrangements for the Congress will be supplied on application to Mr. S. Osborn, Masionnette, Datchet, Bucks, but full particulars have not yet arrived from Germany.

The following papers have been promised from Great Britain as contributions to the Congress: Suggestions to Improve First Aid on Railways, by Mr. James W. Croston; First Aid in the Fire Service, by Mr. Horace Folker; Suggested Rules for Recovering of Coal Mines after Explosions and Fires, by Mr. W. E. Garforth, President of the Mining Association of Great Britain; First Aid and Life-Saving in Coal Mines, by Mr. Albert M. Oppenheimer; and First Aid in the Streets of London, by Mr. S. Osborn, F.R.C.S. Eng.

SANITARY REFORM IN INDIA.

V.[1]—THE PLAGUE PROBLEM.

THE problem demanding solution that has pressed on the Indian Government with the greatest insistence since 1896 is undoubtedly that of plague. This virulent disease has since September of the above-mentioned year been ravaging our Eastern dependency. The difficulties connected with its eradication can be imagined when we consider the peculiar environment which it meets with in the East owing to the crowded insanitary bazaars in which the people live and the care and tact necessary not to offend their social and religious customs. To give some idea of the extent to which plague has flourished in India since its importation there the following facts may be cited. It was carried to the city of Bombay in 1896 from Hong-Kong (where the outbreak occurred in 1893–94), when it burst out as an epidemic in that place in September. From Bombay city it spread over the Presidency where it has continued ever since and has caused, as Professor W. J. R. Simpson tells us, 1,500,000 deaths up to the end of April, 1907. From the Bombay Presidency it has spread gradually to the other provinces of India and has occasioned up to May 31st, 1907, 5,402,245 deaths. The total population in India is about 300,000,000, so that this mortality means about 1 death in every 60 inhabitants. The mortality in the later years has been much greater than that of the earlier, as shown in the following table:—

Year.	Cases.	Year.	Cases.
1896	1704	1902	577,427
1897	56,056	1903	851,263
1898	117,953	1904	1,022,299
1899	134,768	1905	950,663
1900	93,150	1906	332,161
1901	273,659	1907	1,178,989

One of the most serious aspects of the case is the fact that the Punjab is now the seat of a portion of this large mortality, for from the Punjab are drawn some of our most valued recruits; hence it can be easily imagined how the Indian army must suffer. This province has, as a matter of fact, lost nearly 1,700,000 of its inhabitants and this number will at once be seen to be very high when we consider that the Punjab is in size less than one-twelfth of the total area of India, whilst it contains less than one-eleventh of the total population. The plague problem is, indeed, a most urgent and pressing one. The *Times of India* of June 1st, 1907, pointedly remarks:—

> To dismiss this epidemic with the statement that the people of the Punjab have been dying from it for some time past at the rate of 50,000 a week gives but a faint idea of the deserted villages, the crops rotting upon the ground over wide areas for lack of men to reap them, and the breaking up of homes and family life inseparable from such a calamity. ...... Natives of Rawal Pindi who have relations in the plague infected villages will not go to tend their sick; others have left the corpses or belongings of deceased relatives to the mercy of the village rather than risk plague. Firewood is not obtainable to burn the dead, so timber from the houses is being utilised, and many Hindoos are burying their dead.

Professor Simpson well says:—

> The silence of these unharvested fields, together with the figures of mortality, should bring to everyone's imagination a very clear realisation of the awful devastation of the Punjab. ...... The dying millions in India present a problem of the greatest urgency and danger. The plague, if left as it has been within recent years, to take its own course, bids fair in such circumstances to overrun not only India but also to be a danger to the world.

We will now more particularly enter into the subject of plague as it has affected the various provinces of India.

The Punjab.

In the Punjab during the year 1906 there were 120,745 cases of plague reported, of which 104,863 proved fatal. Of these 92 115 deaths occurred in British districts and 12,748 in the Native States. The epidemic, taken as a whole, may be characterised as a very mild one compared with those of the previous four years, the total mortality being much lower than in any year since the general infection over the greater part of the province. This is shown by the figures for the six years 1901–06:—

	Cases.	Deaths.
1901	38,739	20,998
1902	321,938	222,571
1903	341,267	210,697
1904	481,412	402,950
1905	451,791	390,233
1906	120,745	104,863

This low mortality, however, does not encourage the idea that a natural decline in the epidemic had begun, for at the end of 1906 the plague was as bad as ever at the time of year; and it is established by statistics that whilst in the latter half of 1905–06 there was but a small incidence, yet in the first part of 1906–07 the epidemic was as bad as any that had as yet been experienced, if not worse. The total loss that the province has experienced since its first importation in 1897 up to Dec. 31st, 1906, amounts to 1,355,278 lives. As regards the several districts of the Punjab, it is worthy of note that certain of these were escaping the pestilence, although they had suffered in previous years. These districts were those of Hissar, Gurgaon, Shahpur, Jhelum, Jhung, and Lyallpur. With regard to its seasonal prevalence, there seems to be a difference in the seasonal variation in separate parts of the province, inasmuch as the incidence of plague tends to diminish during extreme heat and cold, and especially during the former, so that towards the south with its earlier and longer hot weather the maximum is reached sooner than in the north, the month of maximum intensity being April, although for the whole province it was May; in the south also the freedom during the summer is more distinct, more prolonged, and recrudescence occurs later, opposite conditions to those occurring in the north.

Respecting the type of the disease, by far the largest number of cases are of the bubonic variety, while the fewest are of the septicæmic type. It is satisfactory to note that the people are becoming less suspicious of proffered assistance, although the spirit of self-help is still wanting. The virulence of the disease does not appear to be diminished. With regard to the general plague policy that has been pursued, stress has been laid on the primary importance of preventing, aborting, or delaying recrudescence, inasmuch as it is recognised that the annual seasonal epidemics depend on recrudescence in a large number of places which have been apparently free for some time; from these the disease spreads over the surrounding country. Second to this in members of the medical profession. In this capacity they had strenuously to maintain the highest standard of professional ethics and dignity. Their position as ward-room officers would bring them in daily contact with the best and ablest colleagues in the ship. In this relation they had to maintain a cheerful, but not too hilarious, comradeship with perfect good temper, a measure of dignity (always void of priggishness), and the grace of self-effacement. In short, each would have to be *bonus comes*, which in plain English meant a good fellow. The medical profession was everywhere and always one of self-sacrifice and self-denial. It was therefore a power for refining character. Strictly professional knowledge and experience need not rust, or fall much behind, as was commonly imagined, but it would assuredly do so if the young officer was indolent or casual, or shirked his duties. "Always do the best work you can in the best way you can," continued Sir Dyce Duckworth, who urged his hearers to work diligently at one or two modern languages, and concluded his inspiring address by referring to "one who was once a naval surgeon but rose afterwards to the highest place in the sister service, who was asked at the end of his long and distinguished career, in my presence, if he still believed in *anything*. 'Yes,' he said, '*I do; I still believe in a gentleman.*' I agree with that grand old man," said Sir Dyce Duckworth; "his portrait adorns a neighbouring room here, Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I." If they would maintain that ideal throughout their service they would all reach higher prizes in their profession than any that he had presented that day.

THE STATISTICAL SIDE OF THE OPSONIC QUESTION.

To the Editor of THE LANCET.

SIR,—The statistical portion of the memoir by Dr. Reyn and Dr. Kjer-Petersen which appears in your issue of March 28th raises a question of such importance that I should like to refer briefly to some considerations suggested by it.

Although the statistical side of the opsonic question has been discussed at a meeting of a London society, Dr. Reyn and Dr. Kjer-Petersen are, so far as I know, the first workers to draw public attention to the fact that the significance of opsonic determinations can only be estimated with the help of statistical analysis. They are to be congratulated on their clear enunciation of this important truth, but it is permissible to doubt whether their method of analysis is capable of solving the very complex problems underlying the experimental data. From the use made by Dr. Reyn and Dr. Kjer-Petersen of the "mean error" and the standard deviation as a criterion of the distribution of deviations I infer that what they mean by the "law of error" is the well-known Gauss-Laplace distribution. Now it is by no means clear that calculations based upon this law are valid for phagocytic counts. Although, for reasons which need not be discussed here, a belief has long been entertained that this Gauss-Laplace law was the final word in the theory of random distributions, statisticians are now pretty well agreed—thanks to the work of Fechner, Bruns, and above all, Karl Pearson—that many distributions cannot adequately be described by means of the "normal curve" and that it is necessary to employ the more general form of which the "normal curve" is a particular case. The application of this process to statistical practice has been rendered possible by the researches of Karl Pearson.

At the London Hospital my colleague Dr. Douglas White and myself have been for some time engaged on this problem and we have found that the distributions of phagocytic counts (for numbers varying from 600 to 1100 cells) are not even approximately "normal," the distribution of the numbers on either side of the mean being highly "skew," the mean and mode not coinciding. It therefore follows that the method of the mean error or any kindred process based on the assumption of a "normal" distribution is not applicable since positive and negative deviations of the same magnitude do not occur with equal frequency. There is, indeed, reason to believe that with an increase in the mean number of bacilli per cell the asymmetry is diminished, but we have no satisfactory evidence that the process used by Dr. Reyn and Dr. Kjer-Peterson is applicable to our data. I think, therefore, that in the absence of more evidence the reasoning of Dr. Reyn and Dr. Kjer-Petersen will not enable one to assign definite limits to the normal range of variation.

There are other points of great interest in this paper to which I should have liked to allude, but this must be postponed. I only venture to trouble you in the matter because a complete statistical analysis of the material at our disposal cannot be ready for a considerable time and I desire to emphasise the urgent necessity of caution in drawing conclusions with respect to this subject. In the mass of papers, both eulogistic and vituperative, which deal with the opsonic method little is to be found having much statistical value. Dr. Reyn and Dr. Kjer-Petersen appear to be the first clinicians who have seriously attempted to grapple with the difficulties.

I am, Sir, yours faithfully,
M. GREENWOOD, jun.,
Director of the London Hospital Statistical Department and Senior Demonstrator of Physiology in the Medical College.
London Hospital, E., April 6th, 1908.

To the Editor of THE LANCET.

SIR,—The article of Dr. Reyn and Dr. Kjer-Petersen on the Opsonins of Tubercle which has just appeared in THE LANCET must be of the greatest interest to workers in this particular field. It is generally recognised that the opsonin technique in the case of the tubercle bacillus presents greater difficulties and affords more sources of error than that which is employed with many other bacteria. This may be partly due to the impossibility of preparing a satisfactory bacterial emulsion without, to some extent, damaging the bacilli in the agate mortar, and partly to the injury that is often done to the contour of the leucocytes by the staining method necessary. Dr. Reyn compares the average count in the case of six normal sera treated separately with a count of the same sera "pooled," and the results are certainly startling. But these observations would have been more instructive had he also published several opsonic estimations of the *same* serum arrived at by different workers and the same counter, and by the same worker and different counters.

The tubercle bacillus is nearly always about 0·2 micron thick but its length varies *from* $1 \cdot 5\,\mu$ *to* $4 \cdot 5\,\mu$ at least. In other words, in the same film we may have some bacilli that are three times as great as others, and to tackle them, presumably, the leucocytes would require to put forth three times the phagocytic effort that would be called for in the case of the smaller specimens. May I venture to suggest that more satisfactory results would be obtained by comparing the sum of the lengths of the bacilli taken up by the leucocytes in each preparation rather than the apparent number of the ingested bacteria? After all what appear to be separate bacilli may often be only portions of one organism, disintegrated in the preparation of the emulsion.

I am, Sir, yours faithfully,
Oban, April 6th, 1908. W. D. ANDERSON.

CORONERS' INQUESTS UPON DEATHS IN SURGICAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 21st, p. 851, Dr. F. J. Waldo, the coroner of the City of London and Borough of Southwark, complains that the Registrar-General's statistics of the deaths which occur under anæsthetics are not of much use from a statistical point of view because they do not state the particular anæsthetic under which they occurred. He then proceeds to review his own experience with regard to the number which have occurred chiefly in two large charitable institutions within his district during the past six and a half years. The statements which he makes are also valueless because not only does he fail to specify the different anæsthetics under which they occurred, but has not indicated the total number of anæsthetic administrations which were conducted during the period in those institutions, a number which could be stated by their medical authorities with a very close approximation to accuracy. He then goes

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Accommodation provided for Strawberry-Pickers in the Dartford Rural District, by Dr. R. A. FARRAR.[1]—A vigorous agitation was carried on a year or two ago regarding the degrading and insanitary conditions to which fruit-pickers from the east of London and elsewhere were submitted during their employment in the strawberry season. Attention was called to this matter in an article in THE LANCET of July 16th, 1904 (p. 167). Dr. Farrar, who had already contributed an interesting report to the Local Government Board on the whole question of accommodation of hop-pickers and fruit-pickers, made a special inquiry last year into the conditions obtaining in the extensive rural district of Dartford, where large quantities of strawberries are grown for the London market and where many complaints had arisen in the past. He found that the considerations which had been brought, by means of his former report, to the notice of Kentish fruit growers, coupled with the agitation referred to, had produced a remarkable improvement. Thus the huts as a rule were found weather-tight; in many cases concrete flooring had been laid down; the supply of straw was ample and clean and the farmers had made increased closet provision. A covered cooking shed was generally provided, although in some instances this very desirable arrangement was still wanting. Several farmers had adopted the suggestion of the medical officer of health and had appointed bailiffs or foremen to supervise the camps. Where this was done the camping grounds were generally kept fairly clean and scavenging was attended to. In almost every camp water is laid on by standpipes from the mains of the Metropolitan Water Board, and the provision of washhouses or washing troughs has increased. In the past it has so often been urged that in the case of fruit-pickers and hop-pickers the conditions of labour and the character of the population preclude any successful attempt to improve the conditions of living and housing that Dr. Farrar's report comes as welcome evidence in the contrary sense.

On the Sanitary Circumstances and Administration of the Sanitary Districts in the Staines Registration District,[2] by Dr. E. P. MANBY.—It is surprising to find that no isolation hospital provision is available in this registration district which has a total population estimated to be over 39,000 and comprises such important residential neighbourhoods as Staines, Sunbury, and Feltham. Such provision has been repeatedly urged by the medical officers of health of the districts concerned and is particularly needed in view of the rapid increase of population which is taking place here as elsewhere on the outskirts of London. Dr. Manby refers to various instances in which isolation of the earliest cases in particular localities or houses, if it had been available, would probably have stopped the spread of diphtheria or scarlet fever. He recommends the formation of a joint hospital district by the Middlesex county council in the absence of mutual agreement between the district councils themselves. Many other serious shortcomings of sanitary administration are brought to light by this report. Special attention is drawn to the bad or unsuitable condition of private slaughter-houses, to the need for closer inspection of the structure of new and old buildings, and to the anomalous position in which the Staines rural council has placed its medical officer of health in regard to the assistance given to him by the local inspector of nuisances.

On the Sanitary Circumstances and Administration of Certain Small Urban Districts in the West Riding,[3] by Dr. R. A. FARRAR.—This report relates to certain typical small urban districts which abound in the neighbourhood of Leeds, Bradford, Halifax, Huddersfield, Barnsley, and Wakefield. Though technically "urban" they are in many cases mere agricultural villages with populations of 500 or even less. Most of them acquired their urban status in the early "sixties" after the passing of the Local Government Act of 1858. The object in attaining such status appears to have been merely to evade the county highway rates. The existence of "urban districts" of this kind creates many difficulties in sanitary administration. No one district, for example, can afford to make satisfactory arrangements for public water-supplies or sewerage, or for the sewerage of the mills which are numerous in this part of Yorkshire. And naturally the system does not conduce to the appointment of efficient or experienced sanitary officers. The account given in this report contains many illustrations of the numerous difficulties which have arisen in the particular areas selected for inquiry, and its most satisfactory feature is the formulation of an important scheme for dealing with no fewer than 28 sanitary districts and replacing them by five new districts corresponding with natural drainage areas, the Colne, Holme, Thunder Bridge Dyke, Dearne, and Don valleys respectively. It is to be hoped that the Local Government Board and the West Riding county council will lose no time in putting this scheme into execution.

On the Sanitary Circumstances and Administration of the Wimborne and Cranborne Rural District, by Dr. W. W. E. FLETCHER.[4]—Dr. Fletcher describes a form of closet met with in this district which consists of a combination under a single roof of storehouse, privy, and piggery. The privy cesspit is separated from the pig run only by a moveable door which does not always prevent escape of excremental matter into the pig's run, on the one hand, or access by the pig to the cesspit, on the other. The conditions of pig keeping and feeding are often in many other respects unwholesome. An instance is given in which meat from a diseased bullock was given to pigs and it is probable that this is a not uncommon cause of tuberculosis in these animals. The district reported on has an important dairying industry. A common defect in the cowsheds is that the channels are too narrow and shallow and consequently soon get blocked with dung, with the result that the hind quarters and udders of the cows get fouled and dirt and dung are apt to get into the milk. Many new houses have been erected during recent years without satisfactory water-supply and the local authority has not insisted upon water certificates in regard to them. Although the district contains over 13,000 persons no attempt is made to examine plans of new buildings or to supervise dwellings in course of erection. Registration of cowsheds commenced only a year ago and no regulations have even now been made under the Dairies and Cowsheds Order.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Woking Urban District.—The district council has recently had the question of infantile mortality under its consideration but the recommendation of the sub-committee as to the appointment of a trained nurse as lady health visitor has not yet been acted upon. A case of anthrax occurred in this district during 1907 in somewhat disquieting circumstances. A bullock found one morning to be seriously ill was promptly slaughtered and a butcher was sent for to cut up and to dress the carcass. This butcher acquired the carcass and probably sold the whole of it within the district for human food, the hide, hoofs, entrails, &c., being sent to London. It was only after an interval of several days that the above facts were brought to light by the occurrence of a case of external anthrax in a man who had helped to dress the carcass. This man after operation subsequently recovered but further inquiries led to the discovery that the farm foreman, who also helped to dress the bullock, had died recently from "septicæmia" or what was more probable from internal anthrax. Dr. R. W. C. Pierce, the medical officer of health, has done well to bring these facts to light as they illustrate the dangers which the public incur in the absence of public slaughter-houses. Some machinery is clearly desirable in rural districts whereby animals before slaughter may be inspected by a responsible official.

The Borough of Chelmsford.—In certain particulars the sanitary condition of this borough leaves something to be desired. Although the sewerage and the drainage are, we are told, in a very satisfactory condition, the ventilation of the sewers is apparently a matter of urgency, and notwithstanding the above statement as to the satisfactory condition of the sewerage the medical officer of health is of opinion below is a type. Whose confession of faith—*quâ* anæsthesia—might be briefly expressed somewhat as follows: (1) there is one anæsthetic, and that is chloroform; (2) chloroform may be given anyhow, anywhere, by anyone; (3) if a patient during the course of any anæsthesia shows signs of impending dissolution he is said to take the chloroform badly! (4) if he does nothing of the kind he is said *to take it well*; *(5) if the patient unhappily succumbs*, then it is "an act of God" (as defined by the late Lord Young); (6) an anæsthetist may be defined as "a latter-day nuisance of no use to the surgeon and a curse to the general practitioner"; (7) "there is no need more for the anæsthetist than for a hypodermic injectionist or other poisonist."

[2] Ibid., No. 292. Price 5d.

[3] Ibid., No. 297. Price 6d.

[4] Ibid., No. 300. Price 3d.

Lest I seem to exaggerate let me cite the following. I happened a few days ago to get on to the subject of the teaching of anæsthetics and the present movement in that relation with a surgeon of acknowledged ability and operative dexterity. He immediately gave it as his deliberate opinion that there was no more need for such special instruction than for special instruction in the use of the syringe commonly associated with the name of Higginson! I may say it was put a little more baldly. In reply to my query if "as surgeon in charge of a case he prepared to superintend the anæsthetic and remove some feet of gangrenous bowel, for instance," he replied "Certainly." Time and place scarcely permitted of further discussion, but I challenge that gentleman here and now to amplify his views and state them at length, *coram populo* as it were, and you, Sir, whose motto has always been "Audi alteram partem," will surely afford him the hospitality of your columns. Pray let us hear him. I submit that such an attitude argues a magnificent self-reliance, I had almost said *self-assurance*, and possibly a scarcely justifiable belief in the hyper-development of his five senses. It is plain that either the anæsthesia or the operative technique must suffer under such conditions and I think some ground is given for the remarks occasionally made in certain quarters that patients are too much used as "*clinical material.*" There can be no question as to the greater risk run by the patient.

Now such a position is taken up for several reasons. One is the possession of a hidebound prejudice and unwillingness to accept any sort of reform or progress; another is a determination not to allow anyone or any circumstance to detract from the supremacy and magnitude of the surgeon. To the financial aspect of the question I hardly care to allude; at any rate, that question has been recently threshed out in your columns on general principles by Dr. F. W. Forbes-Ross. It would be unfair and ungracious of me in the extreme if I did not freely and gratefully acknowledge that there are many surgeons who welcome one's presence at an operation and readily admit their disinclination—nay, their incapacity—to take charge of the anæsthetic as well as carry out some grave surgical operation, or indeed a comparatively trifling one. But a class of surgeon and teacher such as I mention exists and has to be reckoned with. And further, they will readily grant a student a certificate as to "instruction in anæsthetics" when possibly the man has merely given chloroform five or six times—in the same theatre in which they are operating.

In the Edinburgh school the late Professor Annandale was the first to recognise the clamant necessity of proper instruction of students, and in view of his seniority all honour to him. On the lines laid down by him some six years ago teaching has since been conducted in the Royal Infirmary, so far as his wards are concerned.

I am, Sir, yours faithfully,

THOMAS D. LUKE,
Lecturer on Practical Anæsthetics at the
University of Edinburgh.

Edinburgh, April 4th, 1908.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Dr. Forbes-Ross admits that "the patient or the patient's friends must needs agree" to the proposed division of fee between the consultant and the general practitioner, and Dr. Saundby concedes that if the facts are fully disclosed the proposed division would be a "perfectly honest and fair transaction." Obviously, if the full facts were *not* disclosed the transaction would amount, as Dr. Saundby points out, to a secret commission received from the consultant by the general practitioner. If the practice advocated by Dr. Forbes-Ross were to become common, how would it work? How would a patient, perhaps a commercial man himself, regard a proposal from his medical attendant in some such form as this? "You need an operation. I recommend Mr. ——. The total fee will be *so much, of which one-third will be returned to me* on the nail for my services in assisting at the operation and afterwards." The patient from his own knowledge of commercial transactions might not improbably ask whether a rebate of one-third was not rather a large one, and whether all surgeons offered the same attractive terms. It is obvious that if one consultant offered a large rebate to the general practitioner and another consultant a small one or none, the practitioner who recommended the former would risk the accusation of desiring the highest rebate rather than the highest skill. No amount of specious argument ought to blind us to the essential dangers of Dr. Forbes-Ross's proposal. In practice it would soon come to mean the bribery of general practitioners by consultants for the sake of gaining their patients, because the system of rebates is not one which in practice could be openly avowed to any patient with common sense.

When Dr. Forbes-Ross says that the general practitioner is as much entitled to be paid for his services in connexion with the operation and afterwards as the consultant all will agree with him. Further, if it were the custom to recognise and pay for those services at the same time as the consultant is paid I think it would be a good practice, but that payment should be made directly by the patient to the general practitioner and never by the consultant out of his fee.

I am, Sir, yours faithfully,

EDWARD DEANESLY, F.R.C.S. Eng.

April 8th, 1908.

THE TREATMENT OF "MANIA"?

To the Editor of THE LANCET.

SIR,—I am under an obligation to THE LANCET in its issue of March 28th for a fair and generous criticism of my little text-book upon "Mental and Sick Nursing," but your reviewer credits me by implication with a want of sympathy in this volume for the so-called "bed treatment" for cases of mania. I need hardly state that this is not the case, for on p. 76 I refer to the great advantage secured by rest in the recumbent position in bed for days together, and during which period I advocate, if the circumstances demand it, a generous treatment of dietary, and in order to save life supplemented if necessary by forced feeding. Again, on pp. 146 and 147 various details are given as to the preparation and administration of nourishment in regard to forced alimentation. Your reviewer somewhat categorically states that the day for the treatment of acute cases of mania by vigorous outdoor exercise is past, but I ventured to point out in my book that such patients when taken out into the freedom of gardens and open places put forth fewer efforts at violence and restlessness than when kept in bed, even when the bed itself is located in the open air. In support of this, witness the struggling of patients tied down to ambulance carriages by various instruments of mechanical restraint and its complete cessation when they are released upon their admission into the asylum, where, I need hardly say, the application of restraint even for acutely maniacal patients is practically unknown.

There seems to be an unsettled tendency in these materialistic days with regard to medical treatment generally, and the flood of pamphlets, vaunting unfailing remedies for the cure of all human ills, which is blown into one's waste-paper basket from Germany and America, and indeed from all the four winds of heaven, is evidence of this, as well as of the inadequacy of the so-called "drug" treatment. We know too well that there are advocates for the exclusive treatment of insanity by medicines, and the old notion is still urged that unless "medicine out of a bottle" is prescribed there is no "hospital treatment." Indeed, I am frequently asked by advocates of this school of treatment, "What drugs do you use directly to affect the brain?" Some, however, wear their rue with a difference and at all cost advocate no drugs, only the exclusive application of "bed treatment"—not infrequently the cause of sleepless and restless nights, tossing off of bedclothes, and consequent chills. Others there are who advocate a rigid dietary with *the sole object of controlling* the "intestinal flora," veritably

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Accommodation provided for Strawberry-Pickers in the Dartford Rural District, by Dr. R. A. FARRAR.[1]—A vigorous agitation was carried on a year or two ago regarding the degrading and insanitary conditions to which fruit-pickers from the east of London and elsewhere were submitted during their employment in the strawberry season. Attention was called to this matter in an article in THE LANCET of July 16th, 1904 (p. 167). Dr. Farrar, who had already contributed an interesting report to the Local Government Board on the whole question of accommodation of hop-pickers and fruit-pickers, made a special inquiry last year into the conditions obtaining in the extensive rural district of Dartford, where large quantities of strawberries are grown for the London market and where many complaints had arisen in the past. He found that the considerations which had been brought, by means of his former report, to the notice of Kentish fruit growers, coupled with the agitation referred to, had produced a remarkable improvement. Thus the huts as a rule were found weather-tight; in many cases concrete flooring had been laid down; the supply of straw was ample and clean and the farmers had made increased closet provision. A covered cooking shed was generally provided, although in some instances this very desirable arrangement was still wanting. Several farmers had adopted the suggestion of the medical officer of health and had appointed bailiffs or foremen to supervise the camps. Where this was done the camping grounds were generally kept fairly clean and scavenging was attended to. In almost every camp water is laid on by standpipes from the mains of the Metropolitan Water Board, and the provision of washhouses or washing troughs has increased. In the past it has so often been urged that in the case of fruit-pickers and hop-pickers the conditions of labour and the character of the population preclude any successful attempt to improve the conditions of living and housing that Dr. Farrar's report comes as welcome evidence in the contrary sense.

On the Sanitary Circumstances and Administration of the Sanitary Districts in the Staines Registration District,[2] by Dr. E. P. MANBY.—It is surprising to find that no isolation hospital provision is available in this registration district which has a total population estimated to be over 39,000 and comprises such important residential neighbourhoods as Staines, Sunbury, and Feltham. Such provision has been repeatedly urged by the medical officers of health of the districts concerned and is particularly needed in view of the rapid increase of population which is taking place here as elsewhere on the outskirts of London. Dr. Manby refers to various instances in which isolation of the earliest cases in particular localities or houses, if it had been available, would probably have stopped the spread of diphtheria or scarlet fever. He recommends the formation of a joint hospital district by the Middlesex county council in the absence of mutual agreement between the district councils themselves. Many other serious shortcomings of sanitary administration are brought to light by this report. Special attention is drawn to the bad or unsuitable condition of private slaughter-houses, to the need for closer inspection of the structure of new and old buildings, and to the anomalous position in which the Staines rural council has placed its medical officer of health in regard to the assistance given to him by the local inspector of nuisances.

On the Sanitary Circumstances and Administration of Certain Small Urban Districts in the West Riding,[3] by Dr. R. A. FARRAR.—This report relates to certain typical small urban districts which abound in the neighbourhood of Leeds, Bradford, Halifax, Huddersfield, Barnsley, and Wakefield. Though technically "urban" they are in many cases mere agricultural villages with populations of 500 or even less. Most of them acquired their urban status in the early "sixties" after the passing of the Local Government Act of 1858. The object in attaining such status appears to have been merely to evade the county highway rates. The existence of "urban districts" of this kind creates many difficulties in sanitary administration. No one district, for example, can afford to make satisfactory arrangements for public water-supplies or sewerage, or for the sewerage of the mills which are numerous in this part of Yorkshire. And naturally the system does not conduce to the appointment of efficient or experienced sanitary officers. The account given in this report contains many illustrations of the numerous difficulties which have arisen in the particular areas selected for inquiry, and its most satisfactory feature is the formulation of an important scheme for dealing with no fewer than 28 sanitary districts and replacing them by five new districts corresponding with natural drainage areas, the Colne, Holme, Thunder Bridge Dyke, Dearne, and Don valleys respectively. It is to be hoped that the Local Government Board and the West Riding county council will lose no time in putting this scheme into execution.

On the Sanitary Circumstances and Administration of the Wimborne and Cranborne Rural District, by Dr. W. W. E. FLETCHER.[4]—Dr. Fletcher describes a form of closet met with in this district which consists of a combination under a single roof of storehouse, privy, and piggery. The privy cesspit is separated from the pig run only by a moveable door which does not always prevent escape of excremental matter into the pig's run, on the one hand, or access by the pig to the cesspit, on the other. The conditions of pig keeping and feeding are often in many other respects unwholesome. An instance is given in which meat from a diseased bullock was given to pigs and it is probable that this is a not uncommon cause of tuberculosis in these animals. The district reported on has an important dairying industry. A common defect in the cowsheds is that the channels are too narrow and shallow and consequently soon get blocked with dung, with the result that the hind quarters and udders of the cows get fouled and dirt and dung are apt to get into the milk. Many new houses have been erected during recent years without satisfactory water-supply and the local authority has not insisted upon water certificates in regard to them. Although the district contains over 13,000 persons no attempt is made to examine plans of new buildings or to supervise dwellings in course of erection. Registration of cowsheds commenced only a year ago and no regulations have even now been made under the Dairies and Cowsheds Order.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Woking Urban District.—The district council has recently had the question of infantile mortality under its consideration but the recommendation of the sub-committee as to the appointment of a trained nurse as lady health visitor has not yet been acted upon. A case of anthrax occurred in this district during 1907 in somewhat disquieting circumstances. A bullock found one morning to be seriously ill was promptly slaughtered and a butcher was sent for to cut up and to dress the carcass. This butcher acquired the carcass and probably sold the whole of it within the district for human food, the hide, hoofs, entrails, &c., being sent to London. It was only after an interval of several days that the above facts were brought to light by the occurrence of a case of external anthrax in a man who had helped to dress the carcass. This man after operation subsequently recovered but further inquiries led to the discovery that the farm foreman, who also helped to dress the bullock, had died recently from "septicæmia" or what was more probable from internal anthrax. Dr. R. W. O. Pierce, the medical officer of health, has done well to bring these facts to light as they illustrate the dangers which the public incur in the absence of public slaughter-houses. Some machinery is clearly desirable in rural districts whereby animals before slaughter may be inspected by a responsible official.

The Borough of Chelmsford.—In certain particulars the sanitary condition of this borough leaves something to be desired. Although the sewerage and the drainage are, we are told, in a very satisfactory condition, the ventilation of the sewers is apparently a matter of urgency, and notwithstanding the above statement as to the satisfactory condition of the sewerage the medical officer of health is of opinion below is a type. Whose confession of faith—*quâ* anæsthesia—might be briefly expressed somewhat as follows: (1) there is one anæsthetic, and that is chloroform; (2) chloroform may be given anyhow, anywhere, by anyone; (3) if a patient during the course of any anæsthesia shows signs of impending dissolution he is said to take the chloroform badly! (4) if he does nothing of the kind he is said to take it well; (5) if the patient unhappily succumbs, then it is "an act of God" (as defined by the late Lord Young); (6) an anæsthetist may be defined as "a latter-day nuisance of no use to the surgeon and a curse to the general practitioner"; (7) "there is no need more for the anæsthetist than for a hypodermic injectionist or other poisonist."

---

[1] London: Wyman and Sons, Fetter-lane; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. No. 283. Price 5d.

[2] Ibid., No. 292. Price 5d.

[3] Ibid., No. 297. Price 6d.

[4] Ibid., No. 300. Price 3d.

Lest I seem to exaggerate let me cite the following. I happened a few days ago to get on to the subject of the teaching of anæsthetics and the present movement in that relation with a surgeon of acknowledged ability and operative dexterity. He immediately gave it as his deliberate opinion that there was no more need for such special instruction than for special instruction in the use of the syringe commonly associated with the name of Higginson! I may say it was put a little more baldly. In reply to my query if "as surgeon in charge of a case he prepared to superintend the anæsthetic and remove some feet of gangrenous bowel, for instance," he replied "Certainly." Time and place scarcely permitted of further discussion, but I challenge that gentleman here and now to amplify his views and state them at length, *coram populo* as it were, and you, Sir, whose motto has always been "Audi alteram partem," will surely afford him the hospitality of your columns. Pray let us hear him. I submit that such an attitude argues a magnificent self-reliance, I had almost said *self-assurance*, and possibly a scarcely justifiable belief in the hyper-development of his five senses. It is plain that either the anæsthesia or the operative technique must suffer under such conditions and I think some ground is given for the remarks occasionally made in certain quarters that patients are too much used as "*clinical material*." There can be no question as to the greater risk run by the patient.

Now such a position is taken up for several reasons. One is the possession of a hidebound prejudice and unwillingness to accept any sort of reform or progress; another is a determination not to allow anyone or any circumstance to detract from the supremacy and magnitude of the surgeon. To the financial aspect of the question I hardly care to allude; at any rate, that question has been recently threshed out in your columns on general principles by Dr. F. W. Forbes-Ross. It would be unfair and ungracious of me in the extreme if I did not freely and gratefully acknowledge that there are many surgeons who welcome one's presence at an operation and readily admit their disinclination—nay, their incapacity—to take charge of the anæsthetic as well as carry out some grave surgical operation, or indeed a comparatively trifling one. But a class of surgeon and teacher such as I mention exists and has to be reckoned with. And further, they will readily grant a student a certificate as to "instruction in anæsthetics" when possibly the man has merely given chloroform five or six times—in the same theatre in which they are operating.

In the Edinburgh school the late Professor Annandale was the first to recognise the clamant necessity of proper instruction of students, and in view of his seniority all honour to him. On the lines laid down by him some six years ago teaching has since been conducted in the Royal Infirmary, so far as his wards are concerned.

I am, Sir, yours faithfully,

THOMAS D. LUKE,
Lecturer on Practical Anæsthetics at the
University of Edinburgh.

Edinburgh, April 4th, 1908.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Dr. Forbes-Ross admits that "the patient or the patient's friends must needs agree" to the proposed division of fee between the consultant and the general practitioner, and Dr. Saundby concedes that if the facts are fully disclosed the proposed division would be a "perfectly honest and fair transaction." Obviously, if the full facts were *not* disclosed the transaction would amount, as Dr. Saundby points out, to a secret commission received from the consultant by the general practitioner. If the practice advocated by Dr. Forbes-Ross were to become common, how would it work? How would a patient, perhaps a commercial man himself, regard a proposal from his medical attendant in some such form as this? "You need an operation. I recommend Mr. ——. The total fee will be so much, of which one-third will be returned to me on the nail for my services in assisting at the operation and afterwards." The patient from his own knowledge of commercial transactions might not improbably ask whether a rebate of one-third was not rather a large one, and whether all surgeons offered the same attractive terms. It is obvious that if one consultant offered a large rebate to the general practitioner and another consultant a small one or none, the practitioner who recommended the former would risk the accusation of desiring the highest rebate rather than the highest skill. No amount of specious argument ought to blind us to the essential dangers of Dr. Forbes-Ross's proposal. In practice it would soon come to mean the bribery of general practitioners by consultants for the sake of gaining their patients, because the system of rebates is not one which in practice could be openly avowed to any patient with common sense.

When Dr. Forbes-Ross says that the general practitioner is as much entitled to be paid for his services in connexion with the operation and afterwards as the consultant all will agree with him. Further, if it were the custom to recognise and pay for those services at the same time as the consultant is paid I think it would be a good practice, but that payment should be made directly by the patient to the general practitioner and never by the consultant out of his fee.

I am, Sir, yours faithfully,

April 8th, 1908. EDWARD DEANESLY, F.R.C.S. Eng.

THE TREATMENT OF "MANIA"?

To the Editor of THE LANCET.

SIR,—I am under an obligation to THE LANCET in its issue of March 28th for a fair and generous criticism of my little text-book upon "Mental and Sick Nursing," but your reviewer credits me by implication with a want of sympathy in this volume for the so-called "bed treatment" for cases of mania. I need hardly state that this is not the case, for on p. 76 I refer to the great advantage secured by rest in the recumbent position in bed for days together, and during which period I advocate, if the circumstances demand it, a generous treatment of dietary, and in order to save life supplemented if necessary by forced feeding. Again, on pp. 146 and 147 various details are given as to the preparation and administration of nourishment in regard to forced alimentation. Your reviewer somewhat categorically states that the day for the treatment of acute cases of mania by vigorous outdoor exercise is past, but I ventured to point out in my book that such patients when taken out into the freedom of gardens and open places put forth fewer efforts at violence and restlessness than when kept in bed, even when the bed itself is located in the open air. In support of this, witness the struggling of patients tied down to ambulance carriages by various instruments of mechanical restraint and its complete cessation when they are released upon their admission into the asylum, where, I need hardly say, the application of restraint even for acutely maniacal patients is practically unknown.

There seems to be an unsettled tendency in these materialistic days with regard to medical treatment generally, and the flood of pamphlets, vaunting unfailing remedies for the cure of all human ills, which is blown into one's waste-paper basket from Germany and America, and indeed from all the four winds of heaven, is evidence of this, as well as of the inadequacy of the so-called "drug" treatment. We know too well that there are advocates for the exclusive treatment of insanity by medicines, and the old notion is still urged that unless "medicine out of a bottle" is prescribed there is no "hospital treatment." Indeed, I am frequently asked by advocates of this school of treatment, "What drugs do you use directly to affect the brain?" Some, however, wear their rue with a difference and at all cost advocate no drugs, only the exclusive application of "bed treatment"—not infrequently the cause of sleepless and restless nights, tossing off of bedclothes, and consequent chills. Others there are who advocate a rigid dietary with the sole object of controlling the "intestinal flora," veritably

58 in the two preceding weeks, declined again last week to 35, of which 23 occurred in Glasgow, six in Aberdeen, three in Greenock, and two in Paisley. The 24 deaths from whooping-cough showed an increase of two upon the number in the previous week, and included 11 in Glasgow, four in Edinburgh, four in Aberdeen, and two both in Dundee and in Paisley. Of the 20 deaths attributed to diarrhœa, 11 were returned in Glasgow, six in Dundee, and two in Edinburgh. The seven deaths referred to "fever" corresponded with the number in the previous week, all being certified as due to cerebro-spinal meningitis; five occurred in Glasgow and one each in Leith and Greenock. Three of the five fatal cases of diphtheria were returned in Glasgow and two of the six deaths from scarlet fever in Dundee. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 158 and 133 in the two preceding weeks, further declined to 114 in the week under notice, but exceeded by five the number returned in the corresponding week of last year. The causes of 31, or 4·5 per cent., of the deaths in these eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 23·9 and 27·4 per 1000 in the two preceding weeks, declined again to 26·0 in the week ending April 4th. During the 13 weeks of last quarter the death-rate in the city averaged 25·5 per 1000, the mean rates during the same period being only 17·6 in London and 18·3 in Edinburgh. The 197 deaths of Dublin residents registered in the week under notice showed a decline of ten from the number in the previous week, and included seven which were referred to the principal epidemic diseases, an increase of three upon the low number returned in each of the three preceding weeks; these seven deaths included three from diarrhœa and one each from measles, scarlet fever, whooping-cough, and "fever," but not one either from diphtheria or small-pox. These seven deaths from epidemic diseases were equal to an annual rate of 0·9 per 1000, the death-rate last week from these principal epidemic diseases being equal to 1·4 in London and 1·2 in Edinburgh. The three deaths attributed to diarrhœa in Dublin last week exceeded the numbers in any recent week. The 197 deaths from all causes in the city last week included 25 of infants under one year of age and 69 of persons aged upwards of 60 years; the deaths of infants were fewer than in any recent week. Four inquest cases and one death from violence were registered, and 81, or 41·2 per cent., of the deaths occurred in public institutions. The causes of four, or 2·0 per cent., of the deaths registered in the city during the week under notice were not certified; in London all but one of the 1527 causes of death last week were duly certified, while in Edinburgh the proportion of uncertified deaths was equal to 3·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Alexander Livingston Christie has been placed on the Retired List, at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated March 27th, 1908).

The following appointments are notified:—Fleet Surgeon: F. J. Burns to the *President*, additional, for three months' course at Meath Hospital, Dublin. Staff-Surgeons: A. X. Lavertine, to the *Suffolk*, on recommissioning; and H. O. Whiteside, to the *Vivid*, additional, for the *Theseus*. Surgeons: R. Thompson, to the *Suffolk*, on recommissioning; and A. B. Marsh, to the *Vivid*. Civil Practitioners: L. B. Mudge to be Surgeon and Agent at Gwythian Detachment; J. R. Dee to be Surgeon and Agent at Walton-on-Naze and Walton Creek.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Alan E. Tate, R.A.M.C., to be a Deputy-Assistant-Director-General at Headquarters, vice Lieutenant-Colonel M. W. Russell, R.A.M.C. (dated April 1st, 1908).

Colonel James McNamara is placed on retired pay (dated March 29th, 1908).

Lieutenant-Colonel Michael W. Kerin, from the Royal *Army Medical Corps, to be Colonel*, vice J. McNamara (dated March 29th, 1908).

HONOURABLE ARTILLERY COMPANY OF LONDON.

Surgeon-Lieutenant John F. Taylor to be Surgeon-Captain (dated March 10th, 1908).

IMPERIAL YEOMANRY.

Glamorganshire: Surgeon-Lieutenant Colin C. McCall resigns his commission (dated March 1st, 1908).

VOLUNTEER CORPS.

Rifle: 5th (Irish) Volunteer Battalion, The King's (Liverpool Regiment): Surgeon-Lieutenant John M. Ahern to be Surgeon-Captain (dated March 7th, 1908). 1st Volunteer Battalion, The Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Captain Alexander R. Stoddart to be Surgeon-Major (dated Jan. 31st, 1908). 2nd (Berwickshire) Volunteer Battalion, The King's Own Scottish Borderers: Surgeon-Lieutenant David Skinner is retired, under the conditions of Paragraph 103 of the Volunteer Regulations (dated March 21st, 1908). Galloway Volunteer Rifle Corps: Surgeon-Captain Robert T. Bell Lorraine resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 6th, 1908). 1st Cinque Ports Volunteer Rifle Corps: Peter Millar Waugh to be Surgeon-Lieutenant (dated March 9th, 1908). 1st London Volunteer Rifle Corps: Surgeon-Captain Arthur D. Ducat to be Surgeon-Major (dated March 31st, 1908). 4th (Donside Highland) Volunteer Battalion, The Gordon Highlanders: Surgeon-Major Alexander Nicol to be Surgeon-Lieutenant-Colonel (dated March 10th, 1908). 1st Dumbartonshire Volunteer Rifle Corps: Surgeon-Major John R. F. Cullen to be Surgeon-Lieutenant-Colonel (dated March 4th, 1908). Surgeon-Lieutenant-Colonel John R. F. Cullen resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 5th, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS.)

Welsh Bearer Company: Major Charles Downing (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Welsh Volunteer Infantry Brigade), to be Lieutenant-Colonel, remaining supernumerary (dated March 2nd, 1908).

MEDICAL UNITS IN THE SOUTHERN COMMAND.

The Army Council has decided to locate additional units of the Territorial Force in the Southern Command—viz., one general hospital and one field ambulance at Portsmouth and one cavalry field ambulance at Devizes. Medical training is to be carried out at the R.A.M.C. camp on Salisbury Plain during August.

THE PRIZE DISTRIBUTION AT HASLAR.

At the Royal Hospital, Haslar, on April 6th, Sir Dyce Duckworth, who was accompanied by Sir Herbert Ellis, K.C.B., the Director-General of the Royal Navy Medical Service, presented the prizes and delivered an address to the recently joined surgeons of the Royal Navy who had passed through the course of instruction. The prizes were awarded as follows: The gold medal for hygiene to Surgeon G. B. Scott (St. Bartholomew's Hospital); the silver medal and books for practical analysis, &c., to Surgeon J. McCutcheon (University of Edinburgh); the microscope for tropical medicine, &c., to Surgeon G. Carlisle (Guy's Hospital).

The following is the list of Surgeons who passed out, together with the combined marks obtained at both the London and Haslar examinations.

	Marks.		Marks.
Surgeon Carlisle	4463	Surgeon Babington ...	3537
Surgeon McCutcheon ...	4127	Surgeon Wright	3373
Surgeon Scott	3974	Surgeon Carson	3183
Surgeon Holl	3793	Surgeon Hamilton... ...	2907
Surgeon Petch	3593		

Sir Dyce Duckworth in his address recalled the fact that he had at one time been a member of the service though he had never served afloat, but had a valuable experience under "one of the ablest and kindest inspector-generals of his day, the late Dr. Stewart, well known for his splendid service in combating yellow fever in H.M.S. *Eclair*." He congratulated them all on having entered the King's first and finest service. Referring to the duties which his hearers would soon have to take up, he said that first and foremost they would have to bear in mind that they were medical officers and would have to give proof of their skill and qualities as up as the result of pressing representations made by the commission of inspection which (as described in THE LANCET last year[2]) visited Jeddah and the Red Sea lazarets two years ago is now completed, but it was apparently not in time to be of much use this year for the pilgrims, except towards the end of the Haj. It is said to furnish good water, which is being sold at about 1½d. a tin holding approximately three gallons. There was no dearth of water, however, this year owing to the good rainfall. The clinical character of the disease in Jeddah was very well marked; most of the cases were of a severe form and algidity and cyanosis were specially prominent symptoms. Many cases were fulminant in character; in one instance one of the medical officers himself saw a pilgrim seized with the first symptoms of the disease. These were sudden vomiting and intense watery diarrhœa, the evacuations being shot out "as by a piston," and in a quarter of an hour the man was dead. It will be seen that only 37 cases out of a total 416 are known to have recovered. No doubt, however, several cases that recovered did not come to the knowledge of the authorities.

The recent behaviour of the epidemic along the Hedjaz railway is not easy to follow in detail owing to the scanty nature of the information received by telegram from those regions. The following facts, however, may be gathered from those telegrams. At Hedieh (about 200 kilometres north of Medina) there were no cases between Jan. 25th and 30th and 3 cases and 2 deaths on the 31st. Then followed several days when the records of Hedieh are confused with those of the region between that town and Bir-ul-jedid to the north. Thus, on Feb. 2nd there were 3 cases among men of the 3rd Company of the 2nd Railway Battalion, working between the two named towns; on the 6th there were 7 cases and 1 death "in places beyond Bir-ul-jedid, Hedieh included"; on the 7th 7 cases and 1 death "at Hedieh"; on the 9th 2 cases and 6 deaths; and on the 10th 2 cases and 4 deaths at the same place. Then follows a long silence in regard to Hedieh, and on March 5th a telegram stating that no case had occurred there "for 20 days," followed by another telegram on March 21st to the effect that "there had been no case for 17 days in Hedieh or the neighbourhood."

As to the record of the disease in Bir-ul-jedid itself (where it will be recalled passengers as distinguished from pilgrims did their quarantine) it is still more imperfect. On Jan. 26th 3 cases and 1 death occurred there; on Feb. 3rd no case and 2 deaths, and on the 8th 1 case and 3 deaths; and that is all that is known at present. But greater interest attaches to events at Medaini-Salih, where the improvised pilgrims' quarantine station was established. The *Mahmel* or Holy Caraven arrived there on its return journey on Feb. 24th, coming in two trains, and consisting of an undetermined number of pilgrims (the number has been variously given as 6000, 10,000, and 20,000). It had had apparently 4 cases of cholera with 2 deaths on its journey from Medina to Medaini-Salih. The day after its arrival (Feb. 25th) there were 16 cases of the disease with 5 deaths in the Medaini-Salih camp. Other caravans appear to have arrived there at the same time and all the pilgrims composing them are said to have been suffering from intense thirst. Harrowing scenes seem to have been witnessed on their arrival at the camp; they threw themselves on the vessels containing the water-supply and much of the water was lost in the struggle. The following is the further record of the outbreak in the camp:—

Feb. 26th	9 *cases,*	2 deaths.
,, 27th	10 ,,	5 ,,
,, 28th	21 ,,	4 ,,
,, 29th	1 ,,	7 ,,
March 1st*	0 ,,	1 ,,
,, 2nd†	0 ,,	0 ,,
,, 3rd	8 ,,	3 ,,
,, 4th	5 ,,	3 ,,
,, 5th‡	4 ,,	5 ,,
,, 6th§	1 ,,	2 ,,
,, 7th‖	1 ,,	0 ,,
,, 8th	0 ,,	1 ,,
,, 9th	0 ,,	0 ,,

* And 1 case among a fresh batch of 600 pilgrims.

† But 16 cases and 6 deaths in a fresh batch of 1600 pilgrims.

‡ There were now 10,000 pilgrims in the camp; 96 cases of cholera had occurred to date.

§ The Holy Caravan left. ‖ Fresh caravans still arriving.

Finally, on March 17th it was stated that there had been no fresh case for ten days and on the 21st that there were still no new cases, though 15 convalescent cholera patients remained in hospital and a fresh caravan of 350 pilgrims had arrived only that evening.

The outbreak of plague in Jeddah still continues and the infection has been carried to Yanbo, where it has also caused a considerable mortality. The following figures (for Jeddah) are in continuation of those in my last letter on this subject:—[1]

From Feb. 9th	to Feb. 16th	12 cases,	12 deaths.
,, ,, 17th	,, ,, 22nd	6 ,,	6 ,,
,, ,, 23rd	,, March 1st	11 ,,	11 ,,
,, March 2nd	,, ,, 7th	3 ,,	2 ,,
,, ,, 8th	,, ,, 15th	9 ,,	8 ,,
,, ,, 16th	,, ,, 22nd	4 ,,	4 ,,

Plague seems to have made its appearance in Yanbo on Feb. 13th. It is said to have been imported from Jeddah by the s.s. *Alexandria* which arrived at Yanbo on Feb. 9th, having on board a stoker ill with the disease. The ship was repulsed to Jeddah for disinfection and rat destruction but the infection had already been carried ashore at Yanbo, where the following cases and deaths have since occurred:—

From Feb. 13th	to Feb. 20th	13 cases,	12 deaths.
,, ,, 20th	,, March 5th	11 ,,	10 ,,
,, March 8th	,, ,, 11th	9 ,,	9 ,,
,, ,, 12th	,, ,, 18th	19 ,,	19 ,,

In all, since the beginning of the epidemic in Jeddah, there have been 123 cases of plague and 117 deaths in the two towns of Jeddah and Yanbo.

In addition to the above 4 cases of plague have been imported to the Camaran lazaret, two on board the s.s. *Budric*, and two on the s.s. *Shahallum*, both of which ships were returning from Jeddah, and at the Tor lazaret a single case of pneumonic plague was landed from the s.s. *Abdul-Kader* on March 5th and another from the s.s. *Gharb* on March 15th. The last case was of the septicæmic form, with a hæmorrhagic exanthem; it ended fatally.

Constantinople, March 27th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Ravages of Sleeping Sickness: the Expedition to Rhodesia.

THE Liverpool School of Tropical Medicine, in conjunction with the Government and the British South Africa Company, despatched an expedition in May, 1907, to Rhodesia to study sleeping sickness and the distribution of biting flies which disseminate that disease. Sir Alfred Jones, K.C.M.G., the chairman of the school, has recently received a report from the expedition, dated Madona, Jan. 28th, 1908, specifying that the "fly" glossina palpalis has been found on both sides of the Luapula from Kapwepwi's to Kasiwa's, a village about two days' journey south of Lake Mweru (by Dr. J. O. Spillane and the expedition). It has also been found by Dr. Spillane along the whole of the British coast of Mweru, around the south end of Lake Tanganyika, and also along parts of the larger confluents of the Luapula and Kweru, notably the Mansa and the Kalungwisi. The expedition found it on the Luongo, a short distance from its mouth. From Kasiwa's to Mweru, on the British side, the Luapula is bordered by swampy plains some miles in width, so that the conditions are unfavourable for this fly. On the Belgian side this does not obtain to such an extent, so that the fly is probably present, although the expedition has no definite knowledge as to this. Glossina morsitans, and possibly the closely related pallidipes and longipalpis, is widely spread over the country, however. On the road from Broken Hill to Fort Jameson the expedition found the flies at one spot in the Machinga hills, from the base of these right across the Luangwa to within a day's journey of Petauke and near the Sasare mine. From Fort Jameson to the Luapula they occur from the Luangwa to the base of the Machingas. There is a sudden rise here to the plateau of 2500 feet or so, and on the top of the hills the members of the expedition did not see the flies again until they arrived at the Kasanka river. In this vicinity on to argue for a coroner's inquest in every case of death during general anæsthesia in order to improve the statistics! I venture to think, Sir, that a poorer argument never was put forward upon a matter of importance. He grows dismal at the contemplation of the fact that "the medical man is not compelled by any statutory obligation to report cases of death under anæsthesia to the coroner." What possible use to the community can arise from a coroner's inquest in such cases when the anæsthetic has been administered by a registered practitioner of medicine?

---

[2] THE LANCET, July 13th, 1907, p. 117.

[1] THE LANCET, Feb. 29th, 1908, p. 678.

The consent of the patient and his friends having been previously obtained to the surgical procedure, the anæsthetic is a natural method of attaining that desired object, for the surgical procedure cannot take place without it. In the year 1900 the British Medical Association published the report of their Anæsthetics Committee, which had been at work for nine years investigating the details of 25,920 administrations of anæsthetics. This report is signed by a large number of the best known surgeons, physicians, and special anæsthetists of their day, and extends to 134 large quarto pages, yet the general conclusions contain the following paragraph:—

> From a careful study of the whole facts at their disposal the sub-committee feel that owing to: (1) the large number of factors in the problem; and (2) the personal equations of the numerous recorders it is impossible to arrive at uniformly satisfactory statistics on the several points submitted for their consideration.

Dr. Waldo must either be in ignorance of this well-known committee's work or has a very inflated idea of the value of the opinion of an average coroner's jury of laymen who thus rush in to decide the pathological cause of death where savants have feared to tread. We who daily fulfil the nation's requirements by administering anæsthetics at hospitals and in private practice where the surgeon's help is called for may surely be trusted with the nation's confidence to preserve life wherever and whenever it can be done.

Among the most serious and depressing factors with which we have to deal is an unreasoning fear of an anæsthetic which is increased and fostered by the publication of accounts of deaths during anæsthesia from the coroners' courts (in many cases these are shown not to be due to the anæsthetic but to the nature of the patient's illness or the gravity of the operation). The repetition of the verdicts in accordance with the evidence of qualified medical men does nothing to allay the mischief of the publication of the fatality. If a patient is dying from heart disease in a hospital ward humanity leads us to screen him off from view, not to call aloud to other patients, "Look what may happen to you as a result of rheumatic fever."

Our most carefully collected statistics give the death-rate from chloroform at 1 in 3162 administrations, from ether at 1 in 16.302, and from mixtures of these two anæsthetics at 1 in 5558. The public knows that every surgical operation itself entails some risk of fatal complications and cheerfully accepts it, though this can never be put into figures owing to variation in the personal equation of the patient, his environment, and state of vitality at the time. When a fatal result occurs after an operation neither the public nor the law calls for public inquiry into the cause of death because it is a natural and inevitable consequence that a certain proportion of patients will always die from these well-understood causes. The public also know that given the above statistics with regard to anæsthetic administrations it is a natural result that a certain proportion of patients will die partly also from the anæsthetic.

Now let us inquire in what cases according to the present law an inquest must be held. The Coroners Act only says "where the coroner suspects that the death was of a violent or unnatural kind." When a coroner can be informed by two registered medical men who were present at the death what the patient died from it can hardly, in the first place, be held that he could of his own medical knowledge "suspect" another cause. Secondly, a death in a beneficent unconsciousness cannot be held to be "violent."

Thirdly, what is a "natural death"? Webster's Dictionary, under definition 8 of the word "natural," states "produced or coming in the ordinary course of things." In the ordinary course of things, as I have shown, it has been known for the past 50 years that there must be a definite mortality in general anæsthesia, therefore a death under an anæsthetic administered by a registered medical man, who alone is competent by his training to undertake the work, is not an unnatural death but a death which must and will occur "in the ordinary course of things" in a certain small number of instances. A coroner is not thus bound by law to hold an inquest in these cases but may accept the certificate of the registered medical men present at the time as to the cause of death.

I have shown, Sir, that these inquests are not required by law and that the jury's verdict must merely repeat medical evidence and cannot in any way add to our knowledge. I consider that they are not only a waste of public time and money, but also from my own intimate knowledge assert that they jeopardise the lives of a percentage of patients, for the publication in the press of accounts of such inquests only succeeds in terrifying the nervous and actually increases the mortality under anæsthesia by disseminating a falsely exaggerated idea of its risks, which produces a physical condition of pallor and feeble heart action from mental fear at the moment when such a patient's turn comes for an inevitable surgical operation. I am, Sir, yours faithfully,

H. BELLAMY GARDNER, M.R.C.S.Eng., L.R.C.P.Lond.
Late Instructor in Anæsthetics and Anæsthetist at Charing
Cross Hospital; Anæsthetist at St. Mark's Hospital for
Fistula, the National Orthopædic Hospital, and the
Male Lock Hospital; Assistant Anæsthetist
at the Royal Dental Hospital of
London.

April 6th, 1908.

To the Editor of THE LANCET.

SIR,—The discussion at the Medico-Legal Society on the anæsthetic fatality question so fully reported in to-day's issue of your journal will be read with keen interest by everyone who has to do with anæsthetic work and medical education. I would have very much liked to have been present at the meeting, and I cordially agree with Dr. F. W. Hewitt when he says at least by far the largest proportion of deaths are preventable. That some are quite unavoidable a casual perusal of the Transactions of the Society of Anæsthetists will convince most people and also will serve to make clear to them what exceedingly grave cases the anæsthetist has occasionally to undertake. As to the instruction to which Dr. C. Templeman refers as taking place in Dundee, I think anyone who knows the student must admit that instruction *which is not certificated* cannot be relied on as having taken place in individual cases, and sometimes the student can manage to get a certificate without having ever earned it. Crowded as the present curriculum unhappily—if unavoidably—is, the medical student for the most part does what the enactments of the special examining body he is concerned with compel him to do, and nothing more. There is no shadow of doubt that a comparatively large proportion of men qualify (so far as the obtaining of a diploma is concerned) without ever handling ether or chloroform. As Dr. J. F. W. Silk points out, alarming the public unduly is not desirable in their own interest, but at the same time it is surely best that the public should realise that there is a very considerable risk connected with the administration of anæsthetics which it is mere folly to unduly minimise and which should be adequately arranged for. Certainly screaming columns in the halfpenny press are most undesirable. The coroner's inquest must always be a horror to those occupied in giving anæsthetics. But at the same time if the person responsible wishes it, I think in Scotland it is perhaps undesirably easy to return death occurring from or under chloroform as "from natural causes."

Inquests or no inquests, the main question is more teaching, better teaching, and more experience, *with proper guidance*, for the student, tending, as Sir Alfred Fripp put it, to "the leavening up of the whole profession." This question has already been up on several occasions before the General Medical Council. Last year it was referred to the Education Committee and I understand they decided that the various examining bodies should be recommended to make the teaching of anæsthetics compulsory, and enforce the presentation of a certificate in regard to such instruction by all candidates for their diploma or degree. Doubtless as a result of the memorial sent them from the Medico-Legal Society they will take further action in the matter, since so few of the examining bodies have taken the previous hint. It is to be earnestly hoped, however, that, if the instruction of students in anæsthetic work is made compulsory all round, the Council will see to it that their enactment is framed in such a manner as to be effective and not farcical.

It must be borne in mind that there are a number of surgeons and teachers of whom the gentleman I mention the bequest. The resignation was accepted with much regret but with full recognition of Dr. Murray's public-spirited action. Dr. Murray, as the first holder of the Heath chair, has left a record which will always serve as a standard for those who will follow him in the professorship. Mr. H. J. Hutchens, who has been associated with the College since 1905 first as demonstrator and then as lecturer on bacteriology, has been elected to succeed Dr. Murray. Dr. Murray now succeeds Dr. J. Limont in the University lectureship on medical jurisprudence, Dr. Limont, owing to continued ill-health, having, much to the regret of his colleagues, been obliged to resign his appointment. Dr. Murray will give his first course of lectures during the coming summer session.

Chair of Midwifery.

The lectureship on midwifery has been raised to a professorship. Dr. R. J. Ranken Lyle, the present lecturer on midwifery, has been appointed first professor of midwifery in the University of Durham.

Feeding of School Children in Newcastle.

At its meeting on April 1st the city council of Newcastle passed a resolution that a halfpenny rate should be raised to defray the cost of feeding of school children. The subject of the feeding of school children was first considered by the corporation early in 1907. A special subcommittee of the education committee was appointed, consisting of 24 members, including four members of the medical profession and two representatives of the Charity Organisation Society. This subcommittee was assisted in a consultative capacity by its principal medical officer. Active opposition was raised to the adoption of the Education (Provisions of Meals) Act, 1906, by certain members of the subcommittee who maintained that the case for school feeding was not proved. Those in opposition offered investigation which, however, was not accepted by the subcommittee which reported to the full committee that there was an urgent need for putting into operation the Act of 1906. The report of the subcommittee includes the report of the principal medical officer. This latter report is hardly convincing, as the following extracts will show. He says:—

> Of the ten departments visited I found that seven had never made a list of names and addresses of actual cases. I do not, however, wish it to be inferred from this that the general result of the inquiry is to be distrusted. There was evidently a distinct failure to understand that the inquiry was to be based upon the actual number of indigent cases in the school at the moment, many basing their returns on probabilities. ...... One infants' department returning ten as the number could not show me a single such case in the school at my visit, nor could I detect any on inspection.

On Dec. 18th, 1907, the city council voted £1500 for school feeding. It was very soon found that the committee was being defrauded and it decided now to ask for the investigation which had previously been offered and refused. The results of these investigations have not yet been received.

Newcastle-upon-Tyne Clinical Society.

The last meeting of the session of this society was held on April 2nd. Many cases of considerable interest were exhibited, including a case of paralysis agitans in a man, aged 42 years, shown by Dr. George Hall, in which he had been able to trace a family history of tremor in three generations—viz., the patient's mother, one sister, and two children. The responsible officers of the society would do well to organise their meetings so that more advantage could be obtained from the material at the disposal of the members. The meeting on April 2nd was hopelessly confused for want of a little organisation.

Royal Victoria Infirmary.

Dr. A. Parkin and Dr. George Hall have been elected honorary assistant physicians to the infirmary.

April 7th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Vaccination Fees.

SOME months ago the Aberystwyth board of guardians reduced the vaccination fees of the public vaccinators and the medical men refused to accept them as they considered the remuneration inadequate. The matter was eventually referred to the Local Government Board and that authority drew up a scale of fees on the mileage plan. At the last meeting of the guardians the public vaccinators declined to accept either scale of fees. After some discussion it was decided to invite the public vaccinators to meet the guardians in the hope that some amicable settlement might be arrived at.

Medical Inspection of School Children.

A conference convened by the Cardigan county council and education committee was held on April 2nd. It was intended that the conference should give an expression of opinion as to how far it would be possible for the education authority to act in coöperation with the various sanitary authorities in giving effect to recent legislation regarding the medical inspection of school children. It was explained that £380 were now paid to medical officers in the county. The estimated cost of medical inspection was £250, calculated on the basis of 6*d.* per child. After a discussion, in which the medical officers took part, it was decided to recommend that arrangements should be made to appoint the local medical officers for the purposes of medical inspection. Owing to the inaccessible nature of the districts it was considered inadvisable and expensive to appoint one officer for the whole county, but it is intended that a medical officer will be appointed to supervise and to codify the annual reports made by the local medical men.

Notification of Births Act.

At the request of the county council the conference also considered the advisability of recommending district councils to adopt the Notification of Births Act. The medical officers expressed their views in favour of not adopting the Act at present on the ground that it would be practically impossible and useless in a county composed almost entirely of rural districts with large areas. Mr. J. W. Stephens (Cardigan) pointed out that the person responsible for the notification was not clearly defined in the Act and considered that the Government had dealt cavalierly with the profession and thrust upon it duties repugnant to its best traditions. The conference decided to advise the district councils not to adopt the Act.

Cardiff City Mental Hospital, Whitchurch, Glamorganshire.

The opening of this hospital will take place on April 15th next at 3 P.M., by the chairman of the visiting committee, Councillor Morgan Thomas. The guests will be conducted over the institution by the chairman and the medical superintendent, Dr. Edwin Goodall, formerly medical superintendent of the Joint Counties Asylum, Carmarthen, who has been busily engaged in making preparations for the past 12 months. The new mental hospital is situated about three miles north-west of Cardiff and about a mile from Llandaff railway station on the Taff Vale railway. Special conveyances, however, will take the officials and guests between Cardiff City Hall, Cathays Park, and the Mental Hospital. The scientific side of the equipment of the new hospital is considered to be above the average.

Bristol Royal Hospital for Children and Women.

The annual meeting of the subscribers to this institution was held on March 31st under the presidency of Lord Winterstoke. The medical report stated that during 1907 the in-patients numbered 785 (727 children and 58 women), a decrease compared with 1906. The out-patients numbered 4662, as compared with 5500 in the previous year. The financial statement showed that the total adverse balance against the institution was now about £4000. The committee states that as a result of its special appeal for £10,000 (which will be utilised for freeing the hospital from debt, for building a small scarlet fever annexe, and for improvements in the out-patient department) the sum of £5209 has been already received.

April 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Education of Women.

AT the eighteenth annual meeting of the Scottish Association for the Medical Education of Women it was reported that the number of students on the roll during the summer session, 1907, and the winter session, 1907–08, was 114, which shows a slight increase over the preceding session. While the report regarding the work of the past year is satisfactory, a serious crisis has unexpectedly arisen which believed and looked upon as being the *causa causans* of mental disorder. Moreover, there are not wanting those who consider the fine flower of attainment in the cure of insanity to be the application of serum therapy by intravenous injection, which alone they suggest can control toxic agencies and re-establish the normal bio-chemistry of the vital organs.

After nearly 30 years of experience of mental diseases, ranging considerably over 12,000 cases of all forms and varieties of insanity—using these terms in the sense interpreted by Mercier—I am convinced that the proper treatment of insanity must be the study of each case upon its merits and that to advocate any special treatment as the exclusively correct method is to establish the "idol of a cult" which subsequent experience will inevitably demolish as has already occurred in the past. Whilst so much and strenuous importance appears to be laid upon either the "drug" treatment, or the so-called hospital treatment, or bed treatment in open places, I feel compelled to enter a protest against any one method and also to regret that, in my opinion and that of many others, too little importance is being attached to the purely mental influences—viz., the influence of one *mind* upon another, whereby qualities such as insight, tact, common-sense, inspired by a feeling of brotherhood and sympathy, fail to receive due appreciation. These mental influences are qualities which should have a higher recognition in the treatment of the insane, for they alone can suggest lines of thought which will facilitate to him the normal appreciation of the outside world, these alone are capable unobtrusively of controlling disordered volition—both inwardly by encouraging self-control and outwardly by directing conduct along reasonable and right channels. Surely it will be acknowledged that at all times and in all ages of medical knowledge the cure of disease has not been wholly or entirely by physical means, but by a judiciously utilised appeal to reason associated always with the coöperation of the patient. These qualities, in my opinion, have ceased to secure their due and formerly recognised place in dealing with variations of that subtle *something* which characterises and distinguishes man—viz., the possession not only of consciousness but of self-consciousness, the capacity not only of exercising a "will" but of having an outlook into the unknown future of time and life. The impression is left upon my mind that your reviewer is dominated by an "idol."

I am, Sir, yours faithfully,

Claybury, March 31st, 1908. ROBERT JONES.

THE INTERNATIONAL SOCIETY OF TROPICAL MEDICINE.

To the Editor of THE LANCET.

SIR,—I am in receipt of a letter from Professor Nocht, deputy-chairman of the German Society of Tropical Medicine, in which he states that the first meeting of that society will be held on April 15th–16th, 1908, in Hamburg; and that the members of the German society will be very happy to meet members of allied societies from abroad. Professor Nocht has requested me to make this fact known. The opening meeting will take place at 9 A.M. on April 15th in the Institut für Schiffs- und Tropenkrankheiten, Hamburg.

I am, Sir, yours faithfully,

G. H. F. NUTTALL,
Honorary Secretary-General.

Cambridge, April 3rd, 1908.

WHY SILK?

To the Editor of THE LANCET.

SIR,—Silk may be regarded as a type of the material employed for ligatures and sutures which, after burial in the tissues of the human frame, if neither extruded nor removed, persists for many months or even years. The heading of this letter is suggested by perusal in recent surgical literature of the following cases.

In the "Annals of Surgery" for November, 1907, Mr. H. M. Rigby describes the removal by an iliac incision of a calculus impacted in the ureter. The ureter was closed by silk sutures. Symptoms recurred. Another calculus was removed from the ureter and two more calculi were passed per urethram. Each of these last three calculi had as a nucleus a silk ligature. Mr. Rigby now advocates suturing the ureter with catgut. In THE LANCET of March 21st, 1908, in his first Lettsomian lecture, Mr. Charters J. Symonds records five cases of nephrectomy, performed for tuberculosis of the kidney. In four of these cases the behaviour of the ligature was as follows.

CASE 1.—Operation in 1907. The pedicle was secured with silk. "The loin sinus did not close till the ligature came away nearly six months after operation."

CASE 2.—Operation in March, 1907. The pedicle was secured with silk. "The drainage-tube was removed in two days and apparently primary union followed." "About six weeks after operation the loin became swollen and a low form of suppuration developed." In November, 1907, there was "a return of many of the symptoms existing before nephrectomy." "In the absence of bacilli I attributed the symptoms myself to the loin sinus kept up by the pedicle ligature. This was removed under ether."

CASE 4.—Operation in November, 1907. Material of pedicle ligature not stated, but on Jan. 8th, 1908, seven weeks after operation, "the sinus in the loin, though giving little trouble, will no doubt continue to discharge till the ligature comes away."

CASE 5.—Operation in November, 1897. "The ureter, very thickened, was ligatured and the silk brought out through a rubber drain, into which the end of the ureter was drawn. The ligature came away some eight months after operation." I am, Sir, yours faithfully,

Plymouth, March 25th, 1908. C. HAMILTON WHITEFORD.

CHOLERA AND PLAGUE IN THE HEDJAZ AND ELSEWHERE.

(BY THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

SINCE the time of writing my last letter, published in THE LANCET of Feb. 29th (p. 678) the cholera outbreak in the Hedjaz has almost completely come to an end. In Mecca no cases were observed after Feb. 8th. In Jeddah, where 113 cases of the disease with 95 deaths had been recorded in the week ending Feb. 2nd, only 15 cases and 25 deaths were seen between Feb. 3rd and 8th; on the three following days 5 fresh cases and 8 deaths were registered, and after the 11th not a single case or death appeared to have occurred there. In Yanbo, where 18 cases and as many deaths had occurred in the week ending Feb. 3rd, there were 8 cases and 8 deaths between Feb. 3rd and 13th, 3 cases and 3 deaths between the last-named date and Feb. 20th, and 13 cases with 10 deaths from that date to March 11th.

The total number of cases of cholera in the principal towns of the Hedjaz since the beginning of the epidemic on Dec. 13th last down to March 11th is put at 6378 and that of deaths at 5695. But these figures do not include the statistics of the outbreak to the north of Medina and in connexion with the Hedjaz railway. They are also probably considerably below the truth, even for the towns to which they refer. Written reports are now being received from the health officers of some of those towns and these furnish some details of interest which supplement the bare figures hitherto alone received by telegraph. Thus in Jeddah there were two periods of the epidemic. In the first, which lasted from Dec. 27th, 1907, to Jan. 7th, 1908, some 20 deaths occurred; these all resulted from infection imported by four pilgrims' ships arriving at Jeddah from Yanbo (as described in an earlier letter). Then from Jan. 7th to 17th there was a cholera-free period; on the 17th the caravans began to arrive back at Jeddah from Mecca and a second and much more severe epidemic period set in which lasted until Feb. 11th. In all, 416 cases of cholera with 379 deaths were registered in Jeddah. Of this total 182 cases occurred among Indian pilgrims, 64 among Turkish, 41 among Bokhariots, 24 among Soudanese, 21 among Russians, 16 among Yemenis, 15 among Afghans, 11 among Tripolitans, and the rest among Chinese, Egyptians, native Arabs (only 8 cases), Algerians, Javanese, Tunisians, Bosniacs, Persians, Europeans, Albanians, and Somalis. The maximum period of the epidemic fell on Jan. 24th. Very few cases were isolated in the barrack which *does duty* for a hospital in Jeddah. Most of those afflicted seem to have died in the streets and the sufferings of the pilgrims were greatly increased by torrential rains which fell incessantly for 48 hours. It is stated, however, that the infection did not seem to have been spread by water. The new distilling apparatus which the Turkish Government has put

The Consumption of Tobacco.

In 1907 the tobacco monopoly brought in 377 million francs, being an increase of six million over 1906. There were sold 2½ million kilogrammes of cigars, and about the same quantity of cigarettes; 28½ million kilogrammes of cut tobacco, or in all 33½ million kilogrammes of smoking tobacco. In addition there were sold 5 million kilogrammes of tobacco in powder and a little more than a million kilogrammes of cake tobacco. The sale of cigarettes, which in 1872 brought in scarcely 1 million francs, rose to 17 million in 1882, and for some years remained about this figure. Last year, however, it brought in 72 million, and, moreover, during the last three years the consumption of snuff has markedly increased. On the contrary, the sale of cigars, especially those sold at a penny and a penny-halfpenny, has slightly diminished. During last year the individual consumption per head of tobacco in France was exactly 1 kilogramme, of which 122 grammes represented snuff and 878 grammes tobacco for smoking or chewing. The total sum expended in France upon the consumption of tobacco was nearly half a milliard (i.e., 500 million francs), or 12 francs 66 centimes per head. Of this sum the Treasury gains 92 per cent.

April 6th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis and Pregnancy.

AT a recent meeting of the Berlin Society for Internal Medicine Professor Bumm read a paper on the management of pregnancy in tuberculous women. It was generally acknowledged, he said, that tuberculous disease was aggravated by pregnancy because the disturbances of metabolism incidental to pregnancy rendered the organism less resistant to the specific bacillus. Pre-existing pulmonary tuberculosis therefore tended to make more rapid progress, whilst women having a predisposition to tuberculosis were exceptionally liable to develop the symptoms of it during pregnancy. Tuberculous women ought, therefore, not to marry, or if married they ought not to become pregnant, but as advice to this effect was likely to remain a counsel of perfection it became advisable in such cases to terminate pregnancy by the induction of abortion. The indications for this proceeding have lately become more and more extended, and Professor Bumm, who is the chief of the lying-in department of the Charité Hospital, stated that nearly every week tuberculous pregnant women were sent to him from the medical departments of hospitals, from sanatoriums, and by medical practitioners for the purpose of having abortion induced. This course should, however, be taken only when objective symptoms of tuberculosis were present, for mere suspicion of the existence of the disease based on family history was not a sufficient justification for it. In the late stage of tuberculosis the operation should be avoided as the fatal issue was not only not postponed but might even be hastened by the loss of blood and shock. When pregnancy had advanced beyond the fourth month artificial abortion was quite as exhausting as a normal labour and should therefore be resorted to only in cases of acute laryngeal or pulmonary œdema. Mild cases of tuberculosis, in which the patient's state had become aggravated during the first half of pregnancy, were well suited for the operation, especially when the ophthalmo-reaction was negative notwithstanding the existence of obvious tuberculosis; it has been found that the ophthalmo-reaction reappeared after the occurrence of abortion. The operation should be performed in such a manner that the women do not feel pain and recover quickly, leaving their beds very soon.

Proposed Amalgamation of Berlin Medical Societies.

The Berlin Medical Society has decided to build a house of its own to be called Virchow-Haus. The meetings of the society have hitherto taken place in Langenbeck-Haus, the property of the German Surgical Association which meets only once a year for a period of four days and does not use its premises during the remainder of the year. The necessity of a special home for the Berlin Medical Society is therefore not very obvious. As the funds of this society are not large enough for the expenses of new premises it has been suggested that the other medical societies should join the Berlin Medical Society. The separation of these societies has been for a long time regarded as a drawback. Not less than 68 medical societies have been formed in Berlin and its suburbs, and the majority of the Berlin medical men are members of several of these societies. It has therefore been proposed that the various societies should be amalgamated so that they would form sections of the Berlin Medical Society. The latter would then be the centre where subjects of general interest would be discussed, whilst those of special interest would be left to the sections. If this plan were realised the funds for erecting a special building for the Berlin Medical Society would soon be collected and the house itself would certainly be more useful than if occupied by only one society.

Foreign Body in the Œsophagus.

Professor Hildebrandt showed at a meeting of the Society for Internal Medicine a woman who in January, 1907, had during sleep swallowed a set of artificial teeth. The taking of food became very difficult and she finally was in a state of inanition when in November, 1907, it was found by radiography that the foreign body was situated in the œsophagus just above the cardia. Professor Hildebrandt performed gastrotomy and tried to seize the teeth by forceps passed through the gastric wound. As he, however, did not succeed in this he performed œsophagotomy in the neck, and having introduced large forceps he crushed the foreign body into pieces which were then gradually extracted. Great exertion was necessary to get the pieces out of the œsophagus, and the operation was the more dangerous because the walls of the œsophagus were so thin that when the hand was introduced into it through the gastric opening the pulsation of the heart could be felt. The wound in the œsophagus was then closed by sutures but an opening was left in the stomach through which the patient was fed for some time. Empyema and partial gangrene of the lung occurred afterwards, but the patient, nevertheless, completely recovered.

April 6th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

A Health Bureau for the Schools.

WITH a view to safeguard children against the spread of disease and at the same time to improve the sanitation of houses in the congested quarters of the city, the Board of Education of Budapest is planning the establishment of a bureau of health. Many of the trustees heartily favour the scheme and if enough votes can be secured in the board it will be put to a practical test as soon as the public schools are opened for the full term. The plan is to have the schools visited by medical inspectors who will obtain from the children information as to cases of illness in their homes. The houses in question will then be visited and every effort will be made to guard against the spread of disease and also to improve the existing sanitary conditions. Teachers will be requested to report to the bureau all cases of illness among the pupils and also all houses which they have reason to know are not sanitary.

Leprosy in Bosnia.

Leprosy is said to be on the increase in Bosnia. Till the year 1895 no special precautions were taken with regard to this disease as it was not considered to be contagious. Since that time, however, so many cases have been discovered that the authorities became alarmed and the rebuilding of an ancient "mosche" (temple) at Visegrad on the sea shore for the internment of lepers was resolved on. From the Serajevo Hospital, which has a special building for the reception of leprous patients, it has been recently reported that the prevalence of the disease has greatly decreased in the districts in which Austrians and Hungarians have settled in great numbers.

Spinal Anæsthesia.

At a recent meeting of the Nagyvárad Medical Society Dr. Imre Fischer, surgeon to the Jewish Hospital, read a paper on Spinal Anæsthesia. He said that the objections which were usually made to the use of spinal cocainisation were as follows: (1) that unpleasant after-effects resulted; (2) that there were immediate and remote dangers which were considerable; (3) that cocaine was uncertain in its they are very plentiful and stretch over to the Luapula and up north past Chitambo's through the country to the east of Bangweulu. They may be said to be found in most of the Luapula division. The expedition has found three cases of sleeping sickness, all with a history of having worked in the Katanga mines. All had markedly enlarged glands and appeared perfectly healthy. The fly glossina morsitans was present in the village in which at least one case lived. Considering the thousands from this country who have worked in the Katanga mines it is likely that there are many more cases scattered through North-Eastern Rhodesia as the labour was not drawn from any one particular district. All the work goes to show that the transmission is mechanical. While this is not sufficient to account for the rapid spread of the disease in view of the great difficulty experienced in getting positive results, it is a fact which cannot be too strongly emphasised. There is a tendency to regard glossina palpalis as the only infecting agent. That this is not so has been shown by the work in Uganda where successful transmission experiments were made with glossina fusca. Again, the work on cattle trypanosomes shows that while one or two species are normally concerned in the extension of the disease, it is quite possible to effect this by the use of not only other species of tsetses but also other distinct genera—e.g., stomoxys and tabanids. This surely is sufficient to demonstrate that at present all biting flies, and particularly all species of glossina, must be regarded with suspicion. In this connexion one must refer to the report that some observers in the Congo Free State implicated stegomyia fasciata. This has to be proved. While, perhaps, the task of controlling the spread of sleeping sickness would become impossible if every biting insect had to be considered it is not so with regard to the tsetse flies. The question of the etiology of the disease is in a more unsatisfactory condition than the treatment, at all events from the prophylactic view, and it is most important that some definite effort should be made to find exactly what flies, tsetse and others, are capable of carrying the virus. As to enlarged glands, a fairly large percentage of the natives (roughly from 30 to 40 per cent.) have palpable glands which come chiefly under one group of Dutton and Todd's classification, though there are also many of another group of glands. On puncture the result was found to be uniformly negative. This occurrence of enlarged glands rather complicates the diagnosis, for it means that the statement "every negro with enlarged glands must be considered, until the contrary is shown, to be a case of trypanosomiasis" cannot be accepted for North-Eastern Rhodesia and, presumably, for Nyassaland as well. Consequently, a trained medical officer is the only person who can look for the disease satisfactorily since puncture is necessary. The British South Africa Company should have special medical officers to travel through the country looking for cases and getting them isolated at once. Whether it will be necessary for like measures to be adopted in Nyassaland is uncertain as yet. The chief danger for the Protectorate lies in the spread of the disease to the north end of Lake Nyassa. Trypanosomiasis is endemic on Tanganyika at Vua in the Free State, a short distance above the Congo-Rhodesia border, and between the people on either side of this there is unrestricted communication. Glossina palpalis is found right round the southern end of Tanganyika, so that it is extremely probable that cases of the disease are present in that part of the country. Whether the disease is to be found in German East Africa is not known. At the north end of Nyassa glossina fusca has been found and this, we know, can carry the disease. If once a case reaches a place where these flies occur an epidemic might easily be started. Natives of the Protectorate are carrying loads from Karonga to Kasama, and as large numbers of natives from the Awemba district of North-Eastern Rhodesia have worked in the Katanga, cases probably exist amongst them, and the possibility of their infecting negroes from Nyassaland must not be overlooked. It therefore seems that the north end of Nyassa is the part which requires most attention from the authorities of the Protectorate. It would also be well to bear in mind that natives of the Protectorate have been working in the Katanga and some are only returning home now. Some of these may be infected. In connexion with the foregoing report the British South Africa Company has taken elaborate measures, through Dr. Spillane, to combat the spread of sleeping sickness, with which measures the sleeping sickness expedition of the Liverpool School were possibly not acquainted at the time when their report was sent. Dr. Spillane's report is dated Fort Jameson, Jan. 20th, 1908.

April 7th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Convocation of the University of Durham.

IN accordance with the University regulations a convocation of the University was, as is usual at the end of the winter examinations, held at the College of Medicine, Newcastle-upon-Tyne. In the absence of the warden, Dr. F. B. Jevons, subwarden of the University, presided. Sir Isambard Owen, Principal of Armstrong College, presented the Bishop of Newcastle for the degree of D.D. *honoris causâ*, and in doing so briefly sketched Dr. Straton's career, and concluded by saying that the University of Durham desired to offer the Bishop its cordial and respectful welcome. Ordinary degrees in medicine, surgery, and hygiene were then conferred, and the examiners for the summer examinations in the various faculties were subsequently appointed. Convocation was followed by a luncheon given in the council room of the College of Medicine by the president and members of the College to which the Bishop and many other guests and officials were invited. The various examinations in the Faculty of Medicine were concluded and the lists published on April 3rd.

Alterations of the Dates of Examinations.

The examinations just concluded were the first to be held under the new arrangement which permits of the examinations being held immediately at the end of the winter and summer sessions instead of as heretofore in the middle of the months of April and September. Under the old *régime* the benefit of the vacations was largely destroyed for both the teaching staff and the students and the alteration of the dates of the examinations whereby they are to be held in future at the end of March and the end of July is universally welcomed as being to the advantage of all parties.

Heath Chair of Comparative Pathology and Bacteriology in the University of Durham.

The late Dr. George Yeoman Heath, a former president of the College of Medicine, to whose generosity and attachment to his profession the College is also indebted for the Heath wing and the Heath Surgical Scholarship, left a sum of money to be invested of which the income was to be devoted to the endowment of a chair of comparative pathology and bacteriology. The professorship was founded in 1893 and Dr. George R. Murray, already then well known for his work on the thyroid gland, was elected first Heath Professor. The work of the new appointment was begun in very small quarters but the success which attended Dr. Murray's teaching and administration soon necessitated the provision of further accommodation. This in turn proved insufficient for the needs of the work. In 1905 a beginning was made with the building of the present Heath wing. Dr. Heath's original intention was that a residential college should be built. It was, however, felt that there was not a sufficient demand for a hall of residence among the Newcastle students of medicine. The council of the College, therefore, with the consent of the trustees of the bequest, applied to the Court of Chancery for leave to build laboratories instead of a residential hall. The Court granted the application, accepting the suggestion of the trustees and council that the building should consist of students' rooms on the ground floor, physiological laboratories on the first floor, and laboratories of comparative pathology and bacteriology on the second floor. Into these admirably arranged and well-equipped laboratories Dr. Murray removed his department at the commencement of the winter session 1906. In spite of the interest which Dr. Murray has always had in his department and of the success which has attended his administration and teaching, he has always held that Dr. Heath's real hope was that a time would come when the holder of the Heath Professorship would be a man who would give his whole time to the department. The question of finance stood in the way. But having satisfied himself that he had overcome that difficulty and that he was now able to realise what he believed to be Dr. Heath's wish Dr. Murray placed his resignation in the hands of the council of the College at its meeting on March 4th, explaining his interpretation of the intention of members of the Anti-Opium League, especially those who have no knowledge of local conditions. The Asiatic temperament must be taken into account and requires very careful treatment in matters of such importance as the regulating of an appetite for a mental excitant such as opium. The pleasant sensations that follow a morphine injection are not likely to remain long a secret to those who, having been rudely divorced from their habitual use of opium, are searching about for some means of satisfying the almost irresistible craving which their systems feel for it.

March 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Kew Lunatic Asylum.

THE Government of Victoria has decided that the Kew Asylum grounds shall be sold and the asylum eventually removed. The present building has been long condemned by the official visitors as overcrowded and structurally deficient. A site has been purchased at Heidelberg which is a very picturesque suburb about eight miles from Melbourne. The present building will be retained for benevolent cases until other provision is made.

The Site of the Melbourne Hospital.

The question of a suitable site for rebuilding the Melbourne Hospital continues to be a fruitful topic of controversy. The choice was considered to lie between rebuilding on the present site or moving to what is known as the "pig market"—a larger area about a mile farther from the city. The Premier recently introduced a new factor by offering the hospital committee an area of 15 acres in what is at present a reserve surrounding the Government House set apart for the Governor-General since the inauguration of the Commonwealth. This site is ideal from the standpoint of natural beauty but it is situated on the south side of the river Yarra and would have three other general hospitals within a radius of one and a half miles. It is objected that if the present site is abandoned the new hospital should be moved to the north, as the northern suburbs contain the great bulk of the poorer population. Another objection which has been strenuously urged is that the Government House reserve should be retained for a pleasure ground. The medical staff of the hospital decided some time ago by a substantial majority in favour of the "pig-market" site, but on the Premier's offer being made a number altered their view and a majority is now in favour of moving across the river. The popular objection to this course appears to be so strong, however, that it is possible that the offer may be withdrawn. Meanwhile the hospital committee accepted it subject to the agreement of the Wilson Fund trustees, whose gift of £100,000 carries the right of approval. This approval was withheld and the Premier called a conference of various public bodies interested in the question. No result was arrived at by this meeting and it is now announced that the hospital committee will itself come to a definite conclusion. Had this been done at the outset a great deal of time and discussion would have been saved, for public opinion was prepared to support the committee in anything decided upon until it weakly accepted the suggestion to cross the river.

Mortality among Boarded-out Infants.

During the recent heat wave in Melbourne it was reported by a female inspector that several infants in the care of a registered nurse were in a dying condition. They were removed to the depôt for neglected children and five of them died there within a week, while another succumbed a few days later. The cause of death in each case was given as colitis or entero-colitis. The nurse in question had no fewer than 12 children under her care. The police inspector reported favourably on his knowledge of the conduct of this place and the coroner eventually concluded that there was no evidence for committal and intimated that the authorities might take further action. The Chief Secretary has directed a prosecution.

Municipal Dispensaries for Sydney.

A movement has been made in the city council of Sydney to establish municipal dispensaries. A motion was carried instructing the city solicitor to prepare a clause in the next amending Bill giving the council power to establish dispensaries in the city.

The University of Sydney.

The medical school is expanding so greatly that it has been found necessary to remodel the present school and also to make considerable additions to the building. The new wing will consist of a stone building three storeys in height, the exterior of which will correspond with the existing block, and the cost will be £20,000. The school as rebuilt will be connected by a handsome cloister with the Pathological Museum. On the ground floor of the new wing there will be a bacteriological class-room, laboratory, and preparation-room, with a lecture-room for pathology. The first floor will include class-rooms for materia medica and surgery. A new museum of anatomy will also be provided.

A Remarkable Case.

A curious case of mental aberration from overstrain has occurred in one of the suburbs of Melbourne. An old lady, aged 81 years, had been for some two years entirely bed-ridden. She was nursed by a daughter, a woman aged 53 years, and mother and daughter were so attached that neither would permit any other attendant, although such was available. A neighbour noticing an offensive smell communicated with the police, who discovered that the old lady had been dead for more than a week. The daughter was in a dazed condition and could give no account of the occurrence except the statement that she thought her mother was asleep. Relatives had called at the house three or four days previously and had been informed that the patient was sleeping and was not to be disturbed. When visited by the police the daughter had apparently not taken her clothes off for at least three days, nor was there any evidence that she had partaken of any food during that time. She has since entirely recovered her mental balance.

Vital Statistics.

The estimated population of Sydney district on Dec. 31st, 1907, was 550,600. The birth-rate for the year was equal to 26·32 per 1000 of the population, which is the highest rate recorded for many years. 10·1 per cent. of these births were illegitimate. The death-rate was 11·45 per 1000; the infant mortality rate was 96·3 per 1000 births. The death-rate was unusually high among children, which is accounted for by the effect of a dry season and the prevalence of epidemic whooping-cough.

The Danysz Microbe.

A conference of the chairmen of State boards of public health was held in Sydney to consider the advisability or otherwise of permitting the liberation of the Danysz rabbit microbe on the mainland. The conference consisted of Dr. Frank Tidswell of New South Wales; Dr. W. P. Norris, Victoria; Dr. W. Ramsay Smith, South Australia; Dr. J. S. C. Elkington, Tasmania; and Dr. Lovegrove, Western Australia. The questions referred for consideration were: (1) whether the microbe found amongst rabbits on the mainland is identical with that suggested by Dr. Danysz for the destruction of rabbits; and (2) whether it is advisable to continue the experiments in the mainland with the Danysz microbe. With regard to the first question the conference concluded "that the microbe suggested by Dr. Danysz is specifically identical with the microbes isolated from rabbits captured on the mainland of Australia." As to the second query the conference concluded that under natural conditions the virus would not injuriously affect animals other than rabbits failing the influence of some circumstances at present unforeseen. After having considered all the evidence the conference found that while there was no reason to apprehend injury to animal life in general neither was there any reason to expect any effective destruction of rabbits by the use of the virus. The importation of the virus being now prohibited by Commonwealth law the conference recommended that the prohibition should be maintained. This means that the Government will not undertake any further experiments, nor will it permit private persons to do so. The scheme may practically be regarded as defunct.

Sydney Hospital.

The annual meeting of subscribers to the Sydney Hospital was held on Feb. 18th under the presidency of Sir Harry Rawson, the State Governor. The past year was the most active and progressive in the history of the institution. 4935 in-patients were treated, of whom 376 died; the proportion of deaths, after deducting those occurring within 24 hours after admission, was 5·7 per cent. 2246 operations were threatens not only the existence of the association but even the future of the medical education of women in Edinburgh. Minto House, which since 1894 has been the headquarters of the association and of the Medical College for Women in Edinburgh, has been sold without consultation with the association and has to be vacated at the close of the ensuing summer session. The association has placed itself in communication with the University Court and the Carnegie Trust and has reason to believe that some satisfactory solution of the difficulty will be discovered.

Forfarshire Medical Officership.

After much discussion the Forfar county council has decided to appoint a new medical officer of health at the salary of £300, inclusive of outlays. He is to reside in Forfar or the immediate neighbourhood, and with the consent of the Secretary for Scotland he is to be allowed to engage in consulting but not in general practice.

Honorary Degree at the University of Aberdeen.

The degree of Doctor of Laws was granted on April 7th to Dr. William Dobinson Halliburton, F.R.S., Professor of Physiology, King's College, London.

Hospital Sunday in Glasgow.

The total amount received on Hospital Sunday last year in Glasgow was £5026, being £52 less than in the previous year. The sum divided among the infirmaries was £4800, and the same course was followed in making the division as in previous years—namely, in proportion to the number of fully occupied beds in each infirmary. The allocation was as follows: Royal Infirmary, 593 beds, £2068; Western Infirmary, 543 beds, £1893; and Victoria Infirmary, 241 beds, £839.

The Relief of Incurables.

The directors of the Association for the Relief of Incurables in Glasgow and the West of Scotland in their thirty-third annual report state that during 1907 the association had under its care 399 persons—128 in Broomhill Home, 32 in Lanfine Home, and 239 assisted by the outdoor relief department. Not a few applicants had to be refused on account of the scarcity of vacancies. During the past 33 years the association has permanently aided 2012 persons, of whom 755 were cared for as in-patients and 1221 as out-patients. The permanent character of the relief afforded may be gathered from the fact that last year there were in Broomhill Home 26 inmates who had each been there for more than 15 years, and in five instances for more than 80 years, the actual average being 22·4 years. Many of the patients are very helpless, some even requiring to be fed. In the maintenance account there is a heavy shortage. The income for this purpose was £5534 and the expenditure was £7877, leaving a deficiency of £1843.

Glasgow Dental Hospital.

The first public distribution of prizes in connexion with this hospital took place last week. During the session there have been 46 students in attendance on the lectures. Hitherto both the school and the hospital have been maintained largely by the fees of the students. In no year since the foundation of the hospital have the public subscriptions reached £100. As the hospital is a public charity and only incidentally serves in some manner for the training of dentists it ought to receive more support from the general public.

April 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Insane Returned Emigrants.

A GRIEVANCE of peculiar type (and of specially deplorable origin) to which Irish ratepayers are subjected in the matter of maintenance of pauper lunatics who are not properly chargeable to the district has often been the subject of discussion. The annual report of Dr. F. C. Ellison, resident medical superintendent of the Castlebar Asylum, gives prominence to the subject. Dr. Ellison points out that the number of emigrants who have returned to Ireland suffering from insanity is very serious. They are nearly all females. At the present date over 80 of the inmates of his asylum, or about 11 per cent. of the total number of its occupants, are persons who developed insanity elsewhere than in Ireland. The great preponderance of females among these points, he considers, to the overwhelming mental strain to which young girls must be subjected when they leave their quiet country homes and enter the turmoil and trials of life in American cities. Sometimes the return is voluntary but in other cases it is carried out by compulsory deportation; and the unhappy emigrant victims of insanity are destined thenceforward to remain a burden on the local rates. The facts and figures produced in Dr. Ellison's report form a most powerful argument against the system of emigration.

Health of Belfast.

At a meeting of the city corporation held on April 1st the chairman of the public health committee admitted that "the death-rate from all causes was rather high during the past month." The death-rate was 27·4; the death-rate from chest diseases was 12·2 (the normal rate being, say 7·0) which the medical officer of health says is "largely due to climatic conditions" and "over which they had practically no control." But an attempt should be made to explain why Belfast is so different in its high general death-rate and in its mortality from chest diseases from other similarly situated cities. Four cases of typhus fever were notified during the past month.

April 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Dislocation of the Carpus.

AT a meeting of the Surgical Society held on March 18th M. Delbet gave a short *résumé* of three papers which had been handed to him by M. Ferron, M. L. Bazy, and M. Picqué. The subject dealt with was dorsal dislocation of the os magnum without dislocation of the semilunar, to which, however, were sometimes attached fragments of the scaphoid and of the cuneiform if these happen to be fractured. Fracture of the scaphoid is common and occurs in quite half the cases; as a rule, these injuries are brought about by a fall upon the hand in extension. After the accident the hand is generally found to be in a position midway between flexion and extension, but one constant symptom is an increase in the antero-posterior diameter of the wrist situated on a lower plane than is the case with fracture of the lower extremity of the radius; flexion and extension of the hand are extremely limited. In a certain number of cases phenomena due to nervous compression have been observed, being in most cases caused by interference with the median nerve; as to treatment, massage is quite insufficient and a cutting operation is usually necessary. The result of simple reduction is not, as a rule, as good as that seen in other dislocations. Reduction should only be attempted in quite recent cases, the practitioner being prepared to operate in case this fails.

Statistics as to Students.

It is probable that the number of students for the current year will be considerably smaller than formerly and the following figures may be quoted in support of this argument. Students of law have this year increased by 1000, following an increase of 3000 in the last seven years. Students of medicine have decreased by 1200 and students of pharmacy by 800. The public will now perhaps commence to appreciate the fact that the career of medicine, owing to its disabilities, is becoming much less attractive than before.

The Therapeutics of Colloidal Silver.

At a meeting of the Therapeutical Society held on March 25th M. Hirtz gave an account of four cases of broncho-pneumonia which had recovered very rapidly under injections of colloidal silver. Within 24 hours after the injections the amelioration in the general condition was very marked and the temperature had dropped; no other drug was employed.

Scarlet Fever.

Scarlet fever, which had been decreasing for some time past, has now broken out anew in a virulent form in the barracks of Paris. The epidemic commenced in the suburban district; then the troops in the barrack of Neuilly were attacked and some of them died. There have been 30 cases and three deaths. All the necessary measures to secure the safety not only of the soldiers but of the general population have been taken.

M'Farlane (Z., C.), Charles Aloysius M'Guire (Z., C.), James Graeme M'Kinna (Z., C.), Charles Mackinnon (B., Z., P., C.), Guy Dalzell M'Lean (Z.), John Malcolm Macpherson (Z., C.), Thomas Martin (Z., C.), Osborne Henry Mavor (Z.), William Montgomery (Z.), Neil Morison (P.), Andrew Muir (B.), Michael Murphy (B., P., C.), Andrew Shennan Neilson (B., Z., P.), John Boyd Orr, M.A. (Z., C.), James Purdie (Z., C.), John Clark Pyper (Z., C.), James Francis Quigley (Lambhill), (Z., C.), James Francis Quigley (Rutherglen), (B., P.), Hugh Young Riddell (P.), Edwin Robertson (Z., C.), James Hinton Robertson (Z., C.), James Inglis Robertson (Z.), Samuel Rutherford (B., Z., C.), Frank Shearar (Z.), Neil Islay Sinclair (B.), John Finlayson M'Gill Sloan (Z., C.), Hendrik Cornelius van der Watt Smit (Z., C.), James Smith (B., Z.), Alexander Robert Boag Soga (Z., C.), Roderick Alexander Steven (B.), Lawrence Tweedie Stewart (B., Z.), Ronald Stewart (Z., C.), William Patrick Andrews Stewart (Z., P.), Archibald Hugh Taylor (Z., C.), William Taylor (Z., C.), John Cameron Thomson Teggart (Z., C.), Ernest Graham Young Thom, M.A. (Z., C.), Edward Napier Thomson (C.), Tom Waterhouse (C.), George Milroy Whish (Z., C.), William Herbert Nairne White (B.), William Whitelaw (B., Z., P., C.), William Brockie Wilson (Z., C.), William Long Wilson (B., P.), William Ferguson Wood (C.), Walter Percy Yates (B., P.), and Fergus Hay Young, M.A. (C.).

Women.—Janet Rankine Anderson (Z., C.), Agnes Barr Auchencloss (P.), Muriel May Curtis (B., C.), Jane Malcolm Davidson (Z., C.), Jane Kerry M'Elroy Hunter (Z., C.), Maggie Logan Kirkwood (Z., C.), Barbara Macgregor (P.), Janet Morrison M'Kechnie (Z., C.), Ellen Brown Orr (B., Z.), Isabel Jane Stark (P., C.), Petrina Stewart (Z.), Mary Buchanan Thomson (P.), and Margaret Walker (B., P.).

The following have passed the Second Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (A.), Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

Thomas Adam, M.A. (P., M.), David Rutherford Adams (A., M.), Andrew Clark Anderson (P., M.), Donald Arbuckle (A., M.), James Currie Auchencloss (A.), Charles Auld (A., P.), Robert Blackie Austin (P., M.), John Bruce Baird, B.Sc., (A., P., M.), Charles Stewart Black (M.), John Broadfoot (A., P., M.), Alexander Hogg Brown (M.), James Buchanan (A., P., M.), James Alexander Stewart Burges (P., M.), Thomas Simpson Campbell (A., P., M.), William George Clark (A., P., M.), Robert Hunter Deans (A., P.), James Thomson Dick (A., P.), Donald Downie (P., M.), Peter Drummond (P., M.), Robert Drummond (A., P., M.), Alexander Moffat Dunlop (M.), James Dunlop, M.A. (A., P.), William Deanburn Dunlop (A., P.), Andrew Scobie Findlay (A., P., M.), Nicholas Gebbie (A., P., M.), Robert Gilchrist (A., P., M.), Joseph Graham (A., P.), John Gray (A.), Albert William Gregorson (A.), Archibald Campbell Haddow (A., P., M.), George Haddow (P.), Allan Byars Hamilton (P.), James Jack (A., P., M.), Thomas Joseph Kirk (M.), Alexander Leishmann (M.), James Macallan (P., M.), Donald Christopher Macdonald (A., P., M.), Ian Macdonald (A., P.), Malcolm Angus MacDonald (A., P., M.), William Macewen (A., P.), Alastair Macintyre (A., P., M.), Balfour M'Kean (A., P., M.), John Gladstone Mackenzie (P., M.), Thomas Jones Mackie (A., P.), William Maxwell M'Kie (M.), Murdo Mackinnon (P., M.), Andrew Bruce MacLean (A., P.), William Alexander Maclennan (A.), Archibald M'Leod (P., M.), Murdoch Hugh M'Leod (M.), Alexander Thomas M'Whirter (A., P.), Francis William Martin (M.), Angus Millar (A.), Campbell Lamont Miller, M.A. (A., P., M.), Robert Stewart Miller (P.), John Mitchell (P., M.), John M'Intosh Morgan (M.), John Mowat (A.), Andrew Ross Muir (A., P., M.), Clark Nicholson, M.A. (M.), John Paterson (P., M.), Thomas Paterson (P.), Richard Reid Kirkwood Paton (P., M.), John Penman (A., P., M.), Arthur Poole (P.), Arthur Stanley Richmond (P.), Daniel Wright Ritchie (A., P., M.), Robert Charles Robertson (A., P., M.), John Ivison Russell (A., P.), Joseph Henry Napoleon Felix Savy (A., P.), James M'Alpine Scott, M.A. (A., P., M.), John M'Naught Scott, M.A. (A., P., M.), James David Speid Sinclair (A.), William Sneddon (M.), George Rae Spence (P., M.), John Stewart Richmond Steel (A.), Edward Ernest Stewart (A.), John Stewart (A., P., M.), Thomas Louis Grenet Stewart (P., M.), Gilbert Innes Strachan (A., P., M.), Andrew Edgar Struthers (P., M.), William Oswald Taylor (A., P., M.), Stephen Veitch Telfer (A., P., M.), Harold Edward Whittingham (A., P., M.), James Williamson (Holytown) (M.), George Jackson Wilson (A., M.), and Henry Yellowlees (P., M.).

Women.—Christina Barrowman (M.), Louisa Emma Dodge (P.), Honoria Somerville Keer (M.), Florence Ann Gallagher (P., M.), Jeanie Douglas M'Whirter, M.A. (M.), Agnes Mary M'Michael (A., P., M.), Mary Amelia Pilliet (A., P., M.), Margaret Muir (M.), Florence Elizabeth Sexton (A., P., M.), and Jemima Wallace (A.).

The following have passed the Third Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

Archibald Aitchison (M.), William Shanks Alexander, M.A. (P., M.), John Allan (P., M.), James George Anderson (P., M.), William Anderson (P.), William Hunter Stirling Armstrong (M.), Alexander Ballantyne, M.A. (P.), David Barbour (P.), Edgar Barnes, M.A. (M.), Arthur Munby Bayne (P.), Douglas Morris Borland (P.), Morris William Browdy (P., M.), David Young Buchanan (P., M.), Carl Joseph Barrett Buchheim (P., M.), John Adam Gib Burton (P., M.), James Cairns (P., M.), John Cameron (P.), Andrew Hood Clark (P., M.), Alexander Beck Cluckie (P.), James Lang Cochrane (P., M.), Charles Duguid, M.A. (P., M.), James Kirkwood Dunlop, M.A. (P., M.), Donald Fisher (P.), Thomas Loudon Fleming (P.), Thomas Scott Forrest (P.), William Leonard Forsyth (M.), Robert Gale (P., M.), William Ernest Gemmell (P.), Alexander Gordon Gilchrist (P., M.), Robert Dunlop Goldie (P., M.), George Stevenson Gordon (P., M.), Alexander Thomas Arthur Gourlay (P.), Edward O'Driscoll Graham (M.), John Granger (P., M.), Kenneth Charles Gordon Gray (P., M.), John M'Lean Hendry (M.), William Howie (P.), Bentley Moore Hunter (P., M.), James Walker Jones (P.), John Parlane Kinloch (P., M.), David Neilson Knox (P., M.), William Thomson Lindsay (P., M.), William M'Adam, M.A., B.Sc. (P.), Daniel Conway M'Ardle (M.), William Charles Macartney (M.), Robert M'Carlie (M.), William M'Connell (P., M.), Alexander Macphail Macdonald (P.), Donald M'Intyre (P., M.), Robert Buchanan Forbes M'Kail (P., M.), George Macleod, M.A. (P., M.), Campbell Macmillan (P., M.), John William M'Nee (P.), John Hart M'Nicol (P., M.), Allan M'Pherson (P.), Murdo Mackenzie MacRae (M.), Thomas Marlin (P., M.), William Aubrey Layard Marriott (P., M.), Hyacinth Bernard Wenceslaus Morgan (P.), Findlay Murchie (M.), Frederick Lewis Napier (P.), William Niccol (P., M.), Charles Mill Nicol (P., M.), David Purdie (P., M.), John Robertson (P., M.), Hugh George Robinson (P., M.), Alfred Roemmele (P., M.), William Rutherford (P., M.), William Wilkie Scott (M.), William Alexander Sewell (P., M.), James Johnston Sinclair (P., M.), James Stewart Somerville (P., M.), William Stevenson (P.), Alexander Stewart (P., M.), Arthur Ford Stewart (P., M.), David Campbell Suttie (P., M.), Robert Sweet (P., M.), Duncan Macnab Taylor (P.), Walter Telfer (P.), Aidan Gordon Wemyss Thomson (P.), Charles Herrman Wagner (P.), George Wallace (P., M.), James Brown Whitfield (P., M.), Henry Joseph Windsor (P., M.), John Youngson Wood (P.), David Yellowlees (P.), and Douglas Young (P., M.).

Women.—Euphemia Adamson Hay (P., M.), Mary Cochran Mitchell (P., M.), Jessie Deans Rankin (P.), Margaret Eason Robertson (P., M.), Olive Robertson (P.), Margaret Elizabeth Rutherford (P., M.), Jeanie Hinshaw Stewart (P.), and Ethelwyn Mary Walters (P., M.).

The following passed with *distinction* in the subjects indicated:—

First Examination.—In *Zoology* and *Chemistry*: Samuel Blumenfeld, Norman Veitch Lothian, James Hinton Robertson, and William Brockie Wilson. In *Zoology*: Janet Rankine Anderson, Charles Averill, James Henry Dible, Maggie Logan Kirkwood, James Ronald M'Curdie, Charles Aloysius M'Guire, Thomas Martin, John Boyd Orr, M.A., John Clark Pyper, William Taylor, and William Whitelaw. In *Physics*: John Campbell, James Francis Quigley (Rutherglen), Mary Buchanan Thomson, and Margaret Walker. In *Chemistry*: Robert Patrick Archibald Kirkland and George Milroy Whish.

Second Examination.—In Anatomy and Physiology: Robert Hunter Deans and Thomas Jones Mackie. In Anatomy: James Thomas Dick, Malcolm Angus MacDonald, and William Macewen. In Physiology: John Bruce Baird, B.Sc., and Harold Edward Whittingham. In Materia Medica and Therapeutics: James Buchanan.

Third Examination.—In Pathology: William M'Adam, M.A., B.Sc., George Macleod, M.A., Hyacinth Bernard Wenceslaus Morgan, and Charles Mill Nicol. In Medical Jurisprudence and Public Health: James George Anderson and David Campbell Suttie.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. A. Albu, *privat-docent* of Medicine, and Dr. Karl Bruhns, *privat-docent* of Dermatology, have been granted the title of Professor.—*Breslau*: Dr. Julius Schmidt has been recognised as *privat-docent* of Medicine.—*Florence*: Dr. Galileo Pierallini has been recognised as *privat-docent* of Pathology.—*Halle*: Dr. Max Kauffmann has been recognised as *privat-docent* of Neurology and Psychiatry.—*Naples*: Dr. Salvatore Aiello has been recognised as *privat-docent* of Neurology and Psychiatry.—*Paris*: Dr. A. Lebeau has been appointed Professor of Toxicology.—*Strasburg*: Dr. Walter Berg has been recognised as *privat-docent* of Anatomy.—*Tomsk*: Dr. Pokrovski of St. Petersburg has been appointed Professor of Pathological Anatomy.—*Turin*: Dr. Emilio Megnier has been recognised as *privat-docent* of Children's Diseases and Dr. U. Calamida as *privat-docent* of Laryngology and Otology.

RETIREMENT OF MR. J. WARD COUSINS AND MR. HENRY RUNDLE FROM THE STAFF OF THE ROYAL PORTSMOUTH HOSPITAL.—At a meeting of the governors of the Royal Portsmouth Hospital held in the board room of that institution on March 27th the resignations were accepted of Mr. Ward Cousins after 48 years' service and of Mr. H. Rundle after 34 years' service. Both gentlemen were elected honorary consulting surgeons and cordial votes of thanks were accorded to them for the valuable services which they had rendered to the hospital. As was remarked by one of the speakers, the improvements at the hospital are monuments to Mr. Cousins's zeal and interest in the institution.

HEALTH REPORT OF THE MID-WARWICKSHIRE COMBINED SANITARY DISTRICT.—The Mid-Warwickshire combined sanitary district includes Yardley (rural) in Worcestershire and Crick (rural) in Northamptonshire. In the middle of last year it possessed a total population of 161,710, having increased by 7600 in the course of the year. The greatest part of the increase has been in the Yardley district, which is distinguished also by the fact that, according to Dr. George Wilson's report, it shows the highest birth-rate for the district (26·7 per 1000) and almost the lowest death-rate (11·3 per 1000), being eclipsed in the latter respect, however, by the Rugby urban district with a death-rate of only 9·6 per 1000. The average death-rate for the whole district was 11·9 per 1000 and the average birth-rate action, both as to producing surgical analgesia and also as to the duration of the analgesia; and (4) that attempts at introducing cocaine sometimes failed. In all of Dr. Fischer's cases the technique of the injections was similar to that adopted by most continental surgeons. The steps were as follows: 1. A preliminary hypodermic injection of one centigramme of morphine was administered. 2. Careful preparation of the lumbar portion of the patient's back was carried out over an area extending as far as the middle of the crest of the ilium. The patient should be in the sitting posture if possible, with the body bent forward in the cyclist's "scorching position." The fourth lumbar spine was then found by drawing a line from the highest point of one iliac crest to the same point on the opposite side. 5. The needle was introduced just below and to one side of the tip of the fourth lumbar spine and was directed upward, forward, and toward the median line for a distance of between 2 and 3¼ inches. When the membranes were penetrated a distinct diminution of resistance was noticed. The spinal fluid usually began to drip from the needle as soon as it entered the spinal canal. At first it might be blood-stained but it soon became clear. If after reaching the canal no fluid escaped its flow might be hastened by inducing the patient to cough. A stylet might be passed into the needle to remove any obstruction that might be present.

The Preservation of Milk with Hydrogen Peroxide.

Most methods of rendering milk sterile are objectionable since they require the addition of substances injurious to health or else render the milk less digestible. It has, however, been found that if peroxide of hydrogen is added in the proportion of 0·40 part per 1000 the milk will keep for many days and the number of germs present will actually decrease to a very low number. When pathogenic germs, such as those of enteric fever, cholera, dysentery, or tuberculosis, were added to the milk they could not after the lapse of some time be detected by the most searching bacteriological examination. The taste of the milk is in no wise altered and numerous experiments have shown that the digestibility is the same as before.

An Epidemic of Typhus Fever in Budapest.

Typhus fever has made its appearance in some districts of Budapest. In the space of a very short time more than 100 cases occurred, and so rapid has been its spread that some public buildings have had to be closed. The source of the epidemic has been discovered and measures have been taken to suppress it.

March 28th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Appendicitis in China.

IN the course of an inquiry which I have recently undertaken into the incidence of appendicitis in China I was impressed with the general agreement among medical men practising in all parts of the Empire as to its extreme rarity. Medical men in charge of native hospitals dealing with large numbers of patients yearly speak of it as a disease which they almost never meet with. The only hospitals yielding any returns of it are those which treat foreign patients. The inquiry could not elicit any definite consensus of opinion as to the cause of the universal freedom of the Chinese. Observers at home seem inclined, for the most part, to attribute the cause to a faulty dietary system but a different view is required here. Sir Frederick Treves in his "*System of Surgery*" says, as regards the apparent exciting causes: "Among the most common may be mentioned dyspepsia, the want of efficient masticating teeth, the bolting of food, the eating of indigestible food such as nuts, constipation, diarrhœa, injury to the groin region, excessive exertion, exposure to cold." These points are the commonest features of Chinese life. Dr. John MacGowan of Amoy, who has lived during many years in China, in a recent article in the local press wrote, without reference to appendicitis: "Foreign physicians who have opened hospitals and treated large numbers of those who have consulted them have come to the conclusion that the large majority of the population are below par and are suffering from indigestion. Salted turnip, which is a popular condiment persistently eaten through all the months of the year, is very responsible for this latter ailment. But it is cheap and so the evil has got to be endured. It would be an interesting question to discuss what effect this general and widespread indigestion has upon the character of the people and upon the course of their history." Dr. MacGowan speaks of the Southern Chinese but his experience is borne out by Mr. D. Christie of Mukden in Manchuria, who after 25 years among the Chinese of the North, writing independently, says: "If dyspepsia, indigestible food, and bolting without masticating have any share in the causation of appendicitis, we should have plenty of it here." Dental caries is common among all classes. Dr. P. B. Cousland, of the London Missionary Society, says: "For 20 years I had charge of hospitals and dispensaries in the Swatow district, the beds in the former ranging from 60 to 180. I never operated on a case of appendicitis nor saw any of my colleagues do so." His experience is similar to that of the majority of practitioners in China and, taken in conjunction with the observations of Dr. MacGowan and Mr. Christie, seems to point to the incidence of appendicitis as being one of anatomical peculiarity, as, for example, the racial possession of a longer mesentery than is the case among Anglo-Saxons, when, owing to the natural shortness of the mesentery, the appendix is liable to kink and to twist. Two outstanding features of the Chinest dietary as compared with ours are the smaller amount of sugar consumed per head and the general absence of tinned foods. Meat is very rarely indulged in by the poor and agricultural classes, though it is eaten daily by the middle and upper classes who, nevertheless, eat much less of it than do Europeans. Rice is the main article of food and is prepared in two ways—either quite dry, with all the grains separated from each other, or in the form of a watery sweetened compound called "congee" by Europeans. This latter form is usually reserved for times of sickness. Coffee is never taken and the tea in use is a much milder infusion than would find favour at home. The ban on human dissection by the Government and on post-mortem examinations by relatives leaves me unable to speak at present with any definiteness on the possible anatomical solution of the question so far as Chinese immunity is concerned, but just as the physical features of Chinese faces differ invariably from those of Europeans the analogy might reasonably be inferred as to difference in the anatomical features and relationships of a Chinese appendix, thus rendering it less prone to inflammatory attacks.

Shanghai and the Opium Question.

There has been a good deal of feeling in Shanghai, with regard to the suppression of the opium trade, as to the attitude of some people at home and the late questions in the House of Commons on the subject. The British Government is doing all in its power to reduce the English trade—only harm can result from a too rigid insistence on its immediate and total suppression. It should not be forgotten by philanthropists at home that the whole practical question of suppression is fraught with much difficulty. The Shanghai municipal council is being asked to adopt the unconstitutional procedure of arbitrarily closing the opium shops in the middle of the financial year, without reference to the body of ratepayers. Though it is willing to do all in its power to abolish these places it is not easy to adjust quickly a total loss of over £7000 per annum from licences alone. It has been suggested that the Anti-Opium League in China in return for the support which it has received from the Member for Nottingham East and others, might memorialise the Home Secretary to introduce total prohibition of alcohol in Nottinghamshire. Correspondents from various parts of the Empire, in writing to the Shanghai papers, point out the increasing use of morphine injected hypodermically, and I have recently come across a case of a Chinese who takes one drachm of morphine a day by this method. Not infrequently cases come to hospital with their bodies dotted all over with the prick marks of injection needles. Perhaps the worst feature connected with the suppression question is the crop of opium "cures" which have sprung up—most of them prepared by foreign druggists and nearly all containing morphine as the chief ingredient. A Chinese trying to fight the craving for opium by means of these "cures" would become a hopeless victim to the morphine habit. While I am, of course, entirely in sympathy with any movement in favour of the eradication of the opium habit, I would urge those members of our profession at home who may be called upon to express their opinion about it to deprecate any undue haste on the part of taking evidence on this Bill, but for the most part it has related to the sale of dips and insecticides used in agricultural or horticultural operations. Mr. Jesse Boot, managing director of Boots' Cash Chemists, appeared as a witness on Thursday, April 2nd. He contended that the term "chemist" was not a professional but a trade title. He, however, expressed himself in favour of including in the Poisons and Pharmacy Bill a provision compelling every limited liability company dealing in drugs to employ qualified chemists in every shop or department.

Vivisection (Abolition) Bill.

Mr. Hodge has introduced into the House of Commons a Bill to provide for the total abolition of vivisection. It was read a first time.

Public Health (Markets in Rural Districts) Bill.

A Bill has been introduced into the House of Commons by Mr. Burns, the President of the Local Government Board, "to make the provisions of the Public Health Act, 1875, with respect to the provision and regulation of markets, applicable in rural districts." It has received a first reading as a matter of form.

The Protection of Newly Born Children.

Lord Robert Cecil intended to present a Bill in the House of Commons on Monday "to provide for the better protection of the lives of new-born children." However, the adjournment of the House prevented him from carrying out his intention. The Bill will in all probability be introduced on the first convenient opportunity.

Coroners' Inquests (Railway Fatalities) Bill.

The text of Sir Francis Channing's Bill to amend the law as to coroners' inquests in the case of fatal accidents on railways has now been made public. It was introduced into the House of Commons at the beginning of February and is designed to facilitate the attendance of a representative of the Board of Trade at the inquest.

HOUSE OF COMMONS.

Wednesday, April 1st.

The Milk-supply of London.

Sir Frederick Banbury asked the President of the Local Government Board whether he was aware that the medical officer of the City of London recently reported in some detail upon the unsatisfactory condition of the milk supplied within the City, with suggestions for preventing the contamination of such milk; whether he had received a copy of that report with certain representations from the corporation based thereon; and whether he intended dealing with the subject in his Bill.—Mr. Burns replied: I have received a copy of the report referred to. As I stated in reply to a previous question on this subject, I trust that the effects of the Bill which I hope to introduce will be to secure more satisfactory control over the milk-supply of the country.

Anthrax in Human Beings.

Mr. Ashley asked the President of the Local Government Board whether his attention had been called to the report of the inquest held in the City Coroner's Court on March 11th on the death of Mary Ellen Pooley from anthrax; and whether, having regard to the fact that a death from anthrax was investigated in the same court on Feb. 8th and to the recommendations of the jury, in which the city coroner concurred, that cases of anthrax ought to be included in the list of diseases compulsorily notifiable to medical officers of health, he would take steps to give effect to that recommendation.—Mr. Burns answered: My attention has been called to the report of this inquest. As I have stated in reply to a question by the honourable Member for the Ashford Division, it is competent for a sanitary authority, with the consent of the Local Government Board, to make cases of anthrax in human beings compulsorily notifiable in its district.

Tuberculosis in Ireland.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the prevalence of tuberculosis amongst children attending the elementary schools in Ireland; whether he had any figures or reports bearing upon the subject; and whether he would consider the advisability of ordering an inquiry into this matter, with a view to taking some effective means of mitigating the consequences of the disease amongst these children.—Mr. Birrell furnished the following written reply: My attention has not been specially called to the prevalence of tuberculosis among school children in Ireland, but I am, of course, aware of the regrettable prevalence of the disease in the country generally, and am fully alive to the importance of dealing with the subject. The Commissioners of National Education have no statistics as to the number of children affected with tuberculosis. They inform me that they have taken what steps they may to prevent the spread of tuberculosis by the exhibition of notices in the schoolrooms calling attention to the danger of the disease. The Tuberculosis Prevention (Ireland) Bill, which is in course of preparation, will provide for the compulsory notification of the disease and will contain other provisions for dealing with the evil. In view of the proposed legislation a special inquiry into the case of the school children does not seem to be necessary.

The Children's Bill.

The adjourned debate on the Children's Bill was resumed and after discussion the motion for the second reading was agreed to.

Thursday, April 2nd.

Meat Inspection.

Captain Faber asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether, seeing the loss which was now borne by breeders and butchers through the frequent slaughtering of fat cattle on account of disease, he could see his way to recommend substantial compensation to them and also a uniform system of inspection of meat by qualified men.—Mr. Burns (the President of the Local Government Board) replied: I presume that the disease referred to in this question is tuberculosis. If so, I would point out that the slaughter of animals suffering therefrom is seldom effected at the instance of local authorities; their duties are in the main confined to the examination and seizure of unsound meat intended for the food of men, and hence they do not commonly arise until the animal has been slaughtered. I cannot make any promise with regard to compensation, but I may state that the Local Government Board has issued more than one circular with a view of securing uniformity in the methods of inspection and seizure of meat, and they believe that the views expressed in those circulars are usually acted upon by local authorities.

A Staffordshire Inquest.

Mr. T. F. Richards asked the Secretary of State for the Home Department whether his attention had been called to the death of a man named David Pearson at Tipton, in Staffordshire, upon whose body an inquest was held and a verdict returned of death from natural causes, accelerated by excessive drinking and exposure; whether he was aware that it was alleged that a noxious drug had been given this man; whether, in the circumstances, the authorities had taken the necessary steps to elicit the true cause of this man's death; and whether he intended to take any steps towards making further inquiries into this case.—Mr. Gladstone answered: I have no information as to this case save that contained in the newspaper report which the honourable Member has kindly sent me, but I am making inquiries and will communicate the result to him.

Vivisection and Dog Licences.

Mr. Ellis Griffith asked the Secretary to the Treasury whether it was customary for the authorities of laboratories licensed for vivisection to pay the tax on the dogs which they keep for that purpose; if so, would he state the number of licences issued by the Inland Revenue to such authorities during the last two years; if it be the fact that no such taxes were paid what was the ground of such exemption; and whether applications for such exemptions were made in those cases as provided by Subsection 1 of Section 5 of the Dogs Act of 1906.—Mr. Runciman said in reply: Licence duties are paid on all dogs used for the purposes stated, but no separate record is kept of the precise number of licences thus issued.

A Mysterious Death.

Mr. Gulland asked the Lord Advocate whether he had made inquiries into the circumstances attending the recent death of a boy at Stranraer, which had been attributed to poisoning due to chocolate sweets eaten by him; and if so, whether the inquiries threw any light on the cause of death.—Mr. Shaw replied: Full inquiries have been made regarding this case. The contents of the boy's stomach and intestines have been subjected to analysis without the slightest trace of poison being found. The answer to the second part of the question is in the negative.

Meat Inspection in Scottish Burghs.

Mr. Watt asked the Secretary for Scotland whether he was aware that it was the practice of some local authorities in Scotland to let the burgh slaughter-house to yearly tenants, who reimbursed themselves by the collection of dues from butchers for the use of the slaughter-house, and that these tenants performed the duty of meat inspectors; and would he say what control the local authorities had over the yearly tenants of the burgh slaughter-houses to insure the proper discharge of their duties as official meat inspectors; and would the local authorities demand that these tenants should have the qualifications for meat inspectors specified under Recommendations, Meat—B, by the Royal Commission on Tuberculosis, 1898.—Mr. Sinclair replied (by written answer): I am aware that in several burghs the slaughter-house is let to a local butcher who in some instances reimburses himself by the collection of dues; that in one or two instances known to the Local Government Board the tenants are understood to report diseased or unsound carcasses to the sanitary officials; but that, in the majority of burghs with public slaughter-houses, the sanitary inspector and veterinary surgeon visit daily or at such other intervals as may be necessary for effective supervision. So far as I am aware the local authorities do not demand that the tenants of their slaughter-houses shall possess the qualifications specified by the Royal Commission on Tuberculosis.

Post Office Medical Officer at Coventry.

Mr. James O'Connor asked the Postmaster-General whether he was aware that the medical officer of the post-office at Coventry was about 85 years of age and that many of the staff at Coventry attended other medical men at their own expense, owing to their dissatisfaction with the medical officer's treatment; and whether, in view of his advanced age, steps would be taken to appoint another medical officer.—Mr. Buxton furnished the following written answer: I am having inquiry made and will communicate the result to the honourable Member.

A Seizure of Food in London.

Mr. Courthope asked the President of the Local Government Board whether a quantity of preserved kidneys imported from America had been seized in the City of London as unfit for human food; what quantity of boric acid or other preservative they contained and what quantity of such preservative per gallon and per pound was considered deleterious to health; and when the promised regulations dealing with the importation and sale of unsound food would be issued.—Mr. Burns (by written answer) replied: The answer, as regards the first point in the question, is in the affirmative. Two samples were submitted to the public analyst. In the first case he reported that the fluid in which the kidneys were preserved and the kidneys themselves each contained 2·1 per cent. of boric acid, which was equivalent to 1470 grains per gallon of the fluid and 147 grains per pound of the kidneys respectively. In the other case the analyst's report showed that the kidneys contained 1·46 per cent. of boric acid (equivalent to 102·2 grains per pound), whilst the fluid contained 1·7 per cent. of boric acid (equal to 1190 grains per gallon). The answer, as regards the third point, depends on a number of considerations which cannot conveniently be discussed in reply to a question. I may, however, say that the presence in imported kidneys of proportions of boric acid so large as those given above is decidedly objectionable from the point of view of public health and I am advised that it is wholly unnecessary. I propose to give special attention to imported preserved kidneys in the regulations referred performed at Sydney and 520 at the Moorcliff branch. The finances are more satisfactory. The present Government paid a subsidy of £35 per bed on 295 beds. The total expenditure was £24,812, while the income amounted to £21,909. The cost per bed was £73 11*s.* 6*d.* A new wing was completed at a cost of £23,000.

March 4th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the first professional examination held on March 23rd, 24th, 25th, 26th, 27th, 28th, and 30th, the following gentlemen were approved in the subjects indicated :—

Chemistry and Physics.—William Somerset Birch, King's College; Kenneth Bleckly Clarke and John Stanley Cocks, Guy's Hospital; William Dale, Birkbeck College; John Rhys Davies, University College, Cardiff; Alfred Evan Lewis Devonald, King's College; William Kelsey Fry, Wandsworth Technical Institute; Harold Stanley Groves, Guy's Hospital; William Samuel Hazell, University College, Cardiff; Hugh Granville Hockridge, St. Bartholomew's Hospital; Edmund Basil Jardine, University College; Evan Lawrence Jones and Kenneth John Taylor Keer, Guy's Hospital; Gordon Burnham King, University College; Allan Osborne Knight, Middlesex Hospital; Edmund Thomas Howard Lea, Westminster and King's College Hospitals; Edward MacMahon Mahon, Guy's Hospital; Reginald Victor Martin, St. Mary's Hospital; Charles Harold Medlock, Guy's Hospital; John Millard, Intermediate County School, Towyn, and Birmingham University; Alan Vivian Moberly and Montague Pern, Guy's Hospital; D'Arcy Power, St. Bartholomew's Hospital; Walter Alexander Reynolds, St. Mary's Hospital; John William Thomas, Leeds University; Watkin Watkins, University College, Cardiff; Hamlet Mark Whelan, University College, Cardiff; John Herbert Wiles, Polytechnic Institute; and Leslie Douglas Wright, Guy's Hospital.

Chemistry.—Harold Cane Godding, Guy's Hospital; James Stanley Higgs, St. George's and King's College Hospitals; Samuel Hutchinson, University College; George Gerald Jack, Technical Institute, Wandsworth; Hubert Dennis Shore, Guy's Hospital; and Henry Stanley Young, Birkbeck College and St. Thomas's Hospital.

Physics.—Alfred Beuthin Danby, Guy's Hospital; John Baptist Gregory Dotto, St. Bartholomew's Hospital; Frank Mainwaring Hughes, London Hospital; Guy Algernon Pratt, Guy's Hospital; Marcus Holroyd Patton, Guy's Hospital and Birkbeck College; Walter Graham Reynolds, St. Mary's Hospital; Anthony Wellesley Monckton Sawyer, University College; Abdel Khalek Selim, Guy's Hospital; Harold Tuxford, Middlesex Hospital; and William Cuthbert Whitworth, Guy's Hospital.

Biology.—Charles Beresford Alexander, Liverpool University; Edgar Bernard Argles, St. Mary's Hospital; Stephen Leonard Baker, London Hospital; Hugh Woodward Barnes, King College; Cyril Armand Bernard, Liverpool University; Henry Cecil Billings, London Hospital; William Herbert Blakemore, Manchester University; Thomas Pennington Bremner, Liverpool University; Bertram James Brewitt and Roger Orme Bridgman, St. Bartholomew's Hospital; William Hackett Broughton, Manchester University; Charles Grinling Bunn, B.A. Cantab., Cambridge University and Charing Cross Hospital; Charles Frank Burton, London Hospital; Guy Kenneth Butterworth, St. Mary's Hospital; Alfred Fisher Camp, University College, Reading; Kenneth Bleckly Clarke, Guy's Hospital; Henry Dyer Scott Close, St. Thomas's Hospital; Alfred Beuthin Danby, Guy's Hospital; John Rhys Davies, University College, Cardiff; Eustace Gregory Edward Ellman, St. Mary's Hospital; Frank Rex Fletcher, London Hospital; Victor William Russell Forbes, Charing Cross Hospital; Edward Dance Fountain, St. Mary's Hospital; Frank Cane Godding, Guy's Hospital; Samuel Sowray Greaves, Leeds University; Francis Henry Guppy, St. Bartholomew's Hospital; Owen Gwatkin, Manchester University; William Samuel Hazell, University College, Cardiff; Shai Kwong Ho, St. Thomas's Hospital; Henry Sydney Colchester Hooper, London Hospital; William Edward Ison, St. Bartholomew's Hospital; Thomas Henry Jackson, Charing Cross Hospital; Edmund Basil Jardine, University College; Evan Lawrence Jones, Guy's Hospital; Ralph Jones, Charing Cross Hospital; William Ben Glynn Jones, Liverpool University; Gordon Burnham King, University College; Claude Kingston, University College, Bristol; Allan Osborne Knight, Middlesex Hospital; John Llewellyn David Lewis, Guy's Hospital; Farquhar MacGillivray Loughnane, St. Thomas's Hospital; Josiah Sherlock Marrington Arthur Haigh Lyne-Evans, St. George's and University College Hospitals; William Fidler Mason, Leeds University; Percy Uredale Mawer, St. Bartholomew's Hospital; Owen Colville Murphy, Middlesex Hospital; Lionel Everard Napier, St. Bartholomew's Hospital; Henry Barton Owens, Robert Charles Parry, and Henry Ray Parsloe, London Hospital; John Rowland Payne, University College, Cardiff; Leonard Robert Pickett, Tonbridge School; Oswald Pitt, Manchester University; Stanley Owen Rashbrook, London Hospital; Geoffrey Bower Richardson, St. Bartholomew's Hospital; Joseph Edward Rivers, Manchester University; Alexander Elder Saunderson, Liverpool University; Anthony Wellesley Monckton Sawyer, University College; Bernard Edward Patrick Sayers, Middlesex Hospital; Frederic Simpson, Charing Cross Hospital; Lindsay Olive Smith, London Hospital; Thomas Joseph Taunton, Technical School, Brighton; Arnold Rothwell Taylor, Manchester University; Harold Topham, Leeds University; Arnold Viney, St. Thomas's Hospital; Clement Arthur Webster, Manchester University; Leslie Gordon White, Leeds University; and Stanley Wickenden, Guy's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery of the Royal College of Surgeons of England the following candidates were approved in the subjects indicated :—

Chemistry and Physics.—Richard Guy Ash, Charing Cross Hospital; Stanley Samuel Beare, Middlesex Hospital; John Benson, Merchant Venturers' Technical College, Bristol; Walter Sydney Bevis, Portsmouth Grammar School; Oscar Bullock, Municipal Technical College, Brighton; Reginald Northey Curnow, Birkbeck College; Cecil Lucas Donne, Middlesex Hospital; Reginald Gilbert Farrington, Guy's Hospital; Robert Daniel Gregg, Liverpool University; William Ewart Hallinan, University College, Cardiff; Albert Henry Herbert, Birmingham University; Kenneth George Hoby, Guy's Hospital; Ernest Sharman Huckett, Portsmouth Grammar School; George Dennis Iles, Leeds Technical Institute; William Lowe Jackson, Charing Cross Hospital; Frederic Amos Jaques, Guy's Hospital; Percy Hills Orton, Guy's Hospital; Arthur Hugh Spencer Palmer, Merchant Venturers' Technical College, Bristol; Haydn Peters, Technical College, Swansea; Reginald Wood Powell, Guy's Hospital; John Hampden Ross, Royal Albert Memorial College, Exeter; Edward Bernard Ryley, Municipal Technical School, Hull; Isidore Gittleson Samuels, Royal Albert Memorial College, Exeter; Reginald Alfred Slade, University College, Bristol; and Basil William Tyson, University College, Cardiff.

Chemistry.—Harold Barrett, Birkbeck College; Arnold John Chapman, Birkbeck College; John Eric Rhys Evans, Municipal Technical College, Brighton; Thomas Leonard Fiddick, Guy's Hospital; John Knowles, Charing Cross Hospital; Ronald Victor Payton, Municipal Technical School, Birmingham; William Macqueen Potter, Birkbeck College; Frederick Gordon Pulford, Charing Cross Hospital; Wilfrid Aubrey Rowe, Charing Cross Hospital; Frank Percival Sturdee, Northern Polytechnic Institute, Holloway; Samuel Lloyd Wallis, Wandsworth Technical Institute; and Edgar Olyve Yerbury, South-Western Polytechnic Institute, Chelsea.

Physics.—Kenneth Charles Brough, Birkbeck College; Graham Cotterell, Science and Art Institute, Walsall; James Kenneth Crawford, Leeds Technical Institute; Henry Oswald Dumayne, Birkbeck College; Arthur Raymond Goddard, Middlesex Hospital; Lawrance Richards Haydon, Charing Cross Hospital; James Stacey Robinson, Municipal Technical School, Birmingham; Arnold Victor Shilton, Birmingham University; and Malcolm Lloyd Williams, Science and Art Institute, Walsall.

UNIVERSITY OF LEEDS.—At examinations held recently the following candidates were successful :—

DEGREES OF M.B. AND CH.B.

Second Examination, Part I., Anatomy and Physiology.—J. P. Brown, J. B. Fisher, W. S. Hart, H. N. Ingham, H. V. Lamb, H. S. Raper, C. R. Richardson, B. A. Slocombe, G. V. Stockdale, N. S. Twist, and R. Ward.

DIPLOMA OF L.D.S.

First Professional Examination.—H. R. Bentley, G. S. McKay, and C. F. Salt.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the third examination held in March for the Degree of Bachelor in Medicine the following candidates were successful :—

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—Jabez Ethelbert Dainty (second-class honours); Wilfred Barkes, John Akilade Caulcrick, and Harold Alexander Cooper, College of Medicine, Newcastle-upon-Tyne; Henry Frederick Iliewicz, London Hospital; Charles Marks, College of Medicine, Newcastle-upon-Tyne; *Theresa de Gournay Miller*, London School of Medicine for Women; and Joseph Albert Sacco, William Sacco, Robert Henry Smallwood, William Robert Bistob Unthank, Charles Leslie Wigan, and George Huntly Wood, College of Medicine, Newcastle-upon-Tyne.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

Mark James Aitken (B., P.), James Angus (B., P.), Robert Richmond Archibald, M.A. (B.), Charles Averill (Z.), Robert Brown Bain (P.), Alexander Baird (B., Z.), Johannes Gerhardus Becker (Z., C.), Simon Harry Bloom (P.), Samuel Blumenfeld (Z., C.), Adam Brown (Z., C.), Robert Archibald Brown (P.), William Brown (Z., C.), John Scouler Buchanan (Z.), Edmund Tytler Burke (Z., C.), Norman Cameron (B., C.), John Campbell (P.), John MacDougall Clark (P., C.), George Cochrane (B.), Robert Corbett Corbett (Z.), Daniel Augustine Cush (B., Z.), George Dalziel (B., P.), Alexander Hugh Davidson (Z., P., C.), William Tennent Gairdner Davidson (Z., C.), James Henry Dible (Z., C.), William Beatson Drummond (Z., C.), Joseph Dunbar (Z., C.), Robert Findlay (Z., C.), John Maitland Forsyth (C.), William Forsyth (Z., C.), William Fraser (Z.), John Erskine Fyfe (Z., C.), Leander Lowrie Fyfe (P.), John Joseph Gibb (B., P.), Alexander Muir Gibson (Z., C.), Alexander Glen (Z., C.), Charles Hope Haddow (B., P.), John Reid Haldane (C.), James Stewart Hall (B., C.), James Hamilton (Z.), Daniel Christopher Hayes (B., Z., P.), Alexander Gibson Henderson (C.), Peter Henderson (B., Z.), John Galloway Hendry (B., Z., P.), John Wishart Welsh Hewitt (Z., C.), Thomas Pollock Inglis (Z.), Andries Johannes Joubert (Z., C.), Charles Joseph Kirk (C.), Robert Patrick Archibald Kirkland (Z., C.), Johannes Arnoldus Kruger (C.), William Joseph Brown Lavery (Z., C.), Frank Lawrie (Z.), Norman Veitch Lothian (Z., C.), John Aloysius M'Connochie (Z., C.), John Fergusson M'Creath (Z., C.), James Ronald M'Curdie (Z., C.), Norman

JAGO, W. I., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Warneford, Leamington, and South Warwickshire Hospital.

LAWRIE, D., M.B., M.S. Glasg., has been appointed Assistant Medical Inspector of Schools for the Glastonbury District of Somerset.

NASH, J. T. C., M.D., C.M. Edin., D.P.H. Cantab., has been appointed Medical Officer of Health to the Norfolk County Council.

ORTON, G. HARRISON, M.D., B.C. Cantab., has been appointed Medical Officer in Charge of the X Ray Department at St. Mary's Hospital.

PAGE, H. M., F.R.C.S. Eng., has been appointed Honorary Anæsthetist to Guy's Hospital.

PARKER, GIBSON, M.D. Lond., D.P.H. Cantab., has been appointed Chief Assistant Medical Inspector of Schools for Somerset.

PRICE, FREDERICK W., M.B., C.M. Edin., has been appointed Physician to the Out-patient Department at the Hampstead General Hospital.

SHIPWAY, F. E., M.B., M.S. Cantab., has been appointed Honorary Anæsthetist to Guy's Hospital.

STEVENSON, T. H. C., M.D State Med. Lond., has been appointed Chief Medical Inspector of Schools for Somerset.

WRIGHT, A. B., M.R.C.S., L.R.C.P., has been appointed Honorary Senior Surgeon to the Royal Hospital, Portsmouth.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM, QUEEN'S HOSPITAL.—Third Surgeon to Out-patients. Salary £50 per annum.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board, washing, &c.

BOOTLE HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and apartments.

BRIDGEND, GLAMORGAN COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, attendance, and washing.

BRIDGWATER HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

CAMBERWELL HOUSE ASYLUM, London, S.E.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and laundry.

CAPE TOWN, SOMERSET HOSPITAL.—Junior House Physician and Two Junior House Surgeons. Salary £200 per annum, with quarters and rations.

CARMARTHEN, JOINT COUNTIES LUNATIC ASYLUM.—Second Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board and lodging.

EDMONTON URBAN DISTRICT COUNCIL EDUCATION COMMITTEE.—School Medical Officer. Salary £250, rising to £300.

EGYPTIAN GOVERNMENT, KASR EL AINY HOSPITAL.—Resident Surgical Officer. Salary £250 per annum, with quarters, servants, washing, coal, and light.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge road, London, S.E.—Honorary Anæsthetist. Also House Physician for nine months, and House Surgeon for six months. Salary in each case at rate of £60 per annum, with board, residence, and washing.

GLASGOW, CORPORATION OF, PUBLIC HEALTH LABORATORY.—Junior Assistant Bacteriologist. Salary 3 guineas per week.

HÔPITAL FRANÇAIS, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer. Salary £50 per annum, with board and lodging. Also Third Physician to Out-patients.

HORNSEY TOWN COUNCIL.—Assistant Medical Officer of Health, &c., unmarried. Salary £225 a year, with rooms and board.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, also Assistant Casualty Medical Officer, both for six months, and unmarried. Salary in each case £20, with board and residence. Also House Physician, unmarried, for six months. Salary £20, with board and residence.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer, unmarried. Salary £80 per annum, with board and residence, &c.

LAMBETH INFIRMARY, Brook-street, Kennington-road, S.E.—Fourth Assistant Medical Officer. Salary at rate of £100 per annum, with residential allowances.

LANARK, MIDDLE WARD ISOLATION HOSPITAL.—Resident Physician. Salary £150 per annum, with board, &c.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—House Surgeon for six months. Salary at rate of £50 per annum, with board, &c.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon. Salary at rate of £50 per annum.

LOWESTOFT HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing allowance.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES, Manchester.—Assistant Medical Officer. Salary £100 per annum.

MANCHESTER, UNIVERSITY OF.—Senior Demonstrator in Physiology. Salary £150, rising to £200 per annum.

MARGATE, ROYAL SEA-BATHING HOSPITAL.—Resident Surgeon. Salary at rate of £80 per annum, with board and residence.

MIDDLESEX HOSPITAL, W.—Second Assistant to the Director of the Cancer Research Laboratories. Salary £200 per annum.

NEW HOSPITAL FOR WOMEN, Euston-road.—Clinical Assistant (female) for the Out-patient Department.

NEWCASTLE-ON-TYNE, HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer. Salary £100, with board, lodging, and laundry.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Resident Medical Officer, Salary £80 per annum, with board, residence, and laundry.

NORTHAMPTONSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—School Medical Officer. Salary £300 per annum and travelling expenses.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon, also Assistant House Physician. Salary in each case £60 per annum, with board, lodging, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician, also House Surgeon, both for six months. Salaries at rate of 50 guineas per annum, with board and residence.

PRESTON, COUNTY BOROUGH OF.—Schools Medical Officer. Salary £250 per annum.

PRESTON, LANCASHIRE EDUCATION COMMITTEE.—School Medical Superintendent. Salary £500 per annum, rising to £650, with expenses.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, London, N.—House Surgeon and House Physician; also Junior House Surgeon and Junior House Physician. All for six months. Salary of two former at rate of £75 per annum, and of two latter at rate of £40 per annum, with board, residence, and laundry.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Four Examiners in Anatomy and Four Examiners in Physiology. Also for the Conjoint Examining Board in England, Three Examiners in Anatomy, Two Examiners in Physiology, Four Examiners in Midwifery, and Two Examiners in Public Health.

ROYAL NAVY, MEDICAL DEPARTMENT.—Examination for not less than 15 Commissions.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon. Salary £100 per annum.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and lodging.

SINGAPORE, STRAITS SETTLEMENTS, MUNICIPAL HEALTH DEPARTMENT.—Assistant Municipal Health Officer, unmarried. Salary $4200, rising to $4800.

SOUTHAMPTON, COUNTY BOROUGH OF.—Assistant Medical Officer of Health. Salary £150 per annum, with residence, board, and washing.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Honorary Assistant Physician.

SOUTHEND-ON-SEA, BOROUGH OF.—Medical Officer of Health. Salary £550 per annum.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried, for six months, renewable. Salary at rate of £70 per annum, with residence, board, and washing.

SOUTH UIST (Southern Division).—Medical Officer. Salary £77 10s.

STAFFORD, STAFFORDSHIRE COUNTY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with board, lodging, and attendance.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—House Physician. Salary £100 per annum, with apartments, board, and washing.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 a year, with board and apartments.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Honorary Registrar and Pathologist.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

BEATTON.—On March 31st, 1908, at The Cliffe, Bradford, the wife of Dr. Gilbert T. Beatton, of a son.

BURROWS.—On April 5th, at Manor Park, London, to Dr. and Mrs. W. Edgcumbe Burrows—a son.

WELLS.—On April 2nd, at Orleans Lodge, Twickenham, the wife of Arthur G. Wells, M.B., B.S. Lond., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

HAMMAND FRASER—MCMULLEN.—On April 2nd, at Brixton Independent Church, S.W., David Hammand Fraser, M.A., M.B., B.C., to Annie Isabel, second daughter of William McMullen, L.R.C.S.I., of Brixton-road, S.W.

MCBRIDE—HULBERT.—On April 2nd, at St. Stephen's Church, Ealing, Walter, second son of P. McBride, M.D., F.R.C.P.E., and F.R.S.E., to Lilian, daughter of Maurice C. Hulbert, J.P.

VAN DEN BERGH—MACDONALD BROWN.—At Hampstead, on April 7th, Enid, only daughter of J. Macdonald Brown, Esq., J.P., M.D., F.R.C.S., of 2, Frognal, Hampstead, to Henry Edward, third son of J. Van den Bergh, Esq., of 26, Lyndhurst-road, Hampstead.

DEATHS

IN MEMORIAM.

WAKLEY.—On April 5th, 1907, at 5, Queen's-gate, S.W., Thomas Henry Wakley, F.R.C.S. Eng., eldest son of the late Thomas Wakley, M.P., and for over 20 years Joint Editor of THE LANCET, aged 86 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

23·7 per 1000. The infantile death-rate, which was 109 in the preceding year, fell during the past year to 88. Dr. Wilson states that in his opinion the Notification of Births Act will have little or no beneficial effect in the rural and small urban districts, and he has not felt warranted in recommending its adoption to any of the district councils for which he acts.

National Union of Public Health Authorities.—A meeting of the provisional council of the above union was held on March 26th at the Grand Hotel, London, for the purpose of considering the rules of the association and the transaction of other business. The draft rules prepared by the chairman and the honorary secretary, after being carefully considered and in a few respects amended, were adopted and ordered to be submitted to a conference of the union to be held on May 28th at Caxton Hall, Westminster.

The Death of Dr. Henry Collier Lecky.—Mr. H. C. Lecky, M.B., B.Ch., D.P.H. Oxon., who since April, 1806, had been in charge of the Brighton bacteriological laboratory, died at the Sussex County Hospital, Brighton, on March 31st. He was only 30 years of age and since the departure from the town of Dr. Arthur Newsholme had been the acting medical officer of health. He was one of the six selected candidates for the position of medical officer of health of Brighton and his death at so early an age is exceedingly sad.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Gustav von Hüfner, professor of physiological chemistry in the University of Tübingen, aged 66 years.—Dr. Dudley D. Saunders, formerly professor of medicine and medical jurisprudence in the Memphis Hospital Medical College.—Dr. Daniel B. St. John Roosa, professor of ophthalmology and otology in the New York Post-Graduate Medical School.—Dr. I. P. Mierzêievski, formerly professor of neurology and mental diseases in the Military Medical Academy of St. Petersburg.

A Memorial to the late Dr. Alfred Lloyd Owen.—In accordance with a very general feeling that some memorial should be erected to the late Dr. Alfred Lloyd Owen, a small committee was formed to further this object. It was felt that the most fitting place in which to perpetuate his memory was within the walls of the Royal Portsmouth Hospital, in which he took the warmest interest and where his chief work of a public character was done. A tablet in alabaster with Irish green marble border has recently been placed in the main corridor of the hospital. The inscription reads—

In remembrance of
Alfred Lloyd Owen, B.A., M.D.
Born Aug 18th, 1845. At Rest July 4th, 1907.
Assistant Surgeon 1870–1874. Surgeon 1874–1906.
Consulting Surgeon 1906–1907
To this Hospital.
A wise Surgeon. A valued colleague.
A follower of all that is good and true.
A man of quick sympathy and high integrity.
Beloved by a wide circle of friends.
Whom he *attracted* by his own capacity for friendship.
Fortiter. Fideliter. Feliciter.
This tablet has been erected by *his friends who* knew and appreciated his good qualities.

Worcestershire Association for the Prevention of Consumption.—The fifth annual report of the Open-air Sanatorium at Knightwick, near Worcester, has been issued by the committee. During 1907 82 cases were under treatment and the accommodation at the institution has been extended considerably. Three new double shelters and a new dining and recreation room with sliding sides have been erected. A new water-supply has been installed, comprising a river pumping station, settling tanks for 5000 gallons, and filter. The drainage has been overhauled and new electric plant installed. It is not surprising that the committee is appealing for increased support. Interesting statistics are given under the heading "Five Years' Experience," showing that of all the "early" cases treated during that period in the sanatorium 90 per cent. are in good health and 82 per cent. are at work. The medical superintendent gives a full account of the routine treatment; the Frimley plan of providing light manual work for selected patients has been employed with benefit. The superintendent states that discharged patients often find difficulty in regaining employment on account of their supposed infectivity. It is much to be regretted if the public are so over-frightened on this point as to deter patients from incurring the "brand" of having undergone sanatorium treatment.

Donations to Hospitals.—The result of Messrs. Raphael Tuck's Postcard Chain Competition, by which among other institutions hospitals have largely benefited, has now been announced. 50 institutions have received prizes, the first six being the Royal United Hospital, Bath (Art prize of the value of £1000); Torbay Hospital, Torquay (cheque for £250), Victoria Hospital, Frome (cheque for £100), Royal Victoria Eye and Ear Hospital, Dublin (Art prize £100), General Hospital, Chester (cheque for £50), and Great Ormond-street Hospital, London, W. (cheque for £50). The complete list of prizes can be obtained in pamphlet form from Messrs. Raphael Tuck, Moorfields, City, London.

Literary Intelligence.—Messrs. J. and A. Churchill will publish shortly new editions of the following books. The eighth edition of a Manual of the Practice of Medicine, by Dr. Frederick Taylor. Besides much additional matter a new feature of the book will be the inclusion of skiagrams.—*The second edition of a* Manual of Ophthalmic Surgery and Medicine, by Mr. W. H. H. Jessop. There will be numerous new illustrations.—The fifth edition of a Short Practice of Midwifery, by Dr. H. Jellett. The work has been considerably enlarged by the inclusion for the first time of coloured plates.—The eighth edition of Qualitative Analysis and Practical Chemistry, by Dr. Frank Clowes.—Also new works, entitled a Manual for Midwives, by Dr. C. J. N. Longridge of Queen Charlotte's Hospital and examiner to the Central Midwives Board. All the 50 illustrations have been specially drawn for the book.—The Thermal Treatment of Aix-les-Bains, by Dr. H. Forestier, physician to the Bathing Establishment of the Thermal Hospital, Aix-les-Bains.

Royal Dental Hospital, Leicester-square, London.—The fiftieth annual general meeting of governors was held at the hospital on March 26th, the Hon. W. F. D. Smith, M.P., being in the chair. The committee of management reported that the total number of patients during the year was 20,643, their attendances being 53,470, and that the total amount received for the general maintenance fund was slightly under that of the previous year—viz., £5146, against £5250. The sums received from King Edward's Fund, the Hospital Sunday Fund, and the Hospital Saturday Fund amounted together to £1002. A legacy of £1000 had been received for the general purposes of the hospital and £225 from the executors of the late Mr. John L. Toole. £1000 had also been bequeathed to the hospital by the late Mr. A. J. Woodhouse, formerly a vice-president of the hospital, to found a scholarship in dental surgery to be called the "Alfred James Woodhouse Scholarship." As regards expenses the year ended with liabilities to tradesmen of £586 and of £790 for the instalment of principal and interest due on the mortgage of £47,400, on which the fixed yearly payment is £2975. The committee earnestly appeals for funds to discharge these liabilities. The bankers are Messrs. Barclay and Co., 1, Pall Mall East, S.W.; the treasurer is Mr. F. A. Bevan, and the secretary is Mr. J. F. Pink.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Resignation of the Prime Minister.

GENERAL sympathy with Sir HENRY CAMPBELL-BANNERMAN was expressed at Westminster when the announcement was made that his very serious illness had necessitated his resignation of the post of Prime Minister. The event was foreseen, although its formal announcement was not expected until Parliament should have in the usual course risen for the Easter vacation. Mr. ASQUITH has been sent for by HIS MAJESTY, who is at Biarritz, and as Parliament could not usefully continue to sit during the rearrangement of ministerial offices both Houses have adjourned until Tuesday, April 14th.

The Official Directory of Nurses Bill.

Lord AMPTHILL has given notice of his intention to move the rejection of Lord BALFOUR of BURLEIGH'S Official Directory of Nurses Bill, when the second reading is moved. This, however, will not occur until the House of Lords reassembles after the Easter Recess.

Poisons and Pharmacy Bill.

The Joint Committee of both Houses of Parliament has been whole plant is stated to produce in time a considerable alleviation of the attacks and when smoked in the form of cigarettes immediate relief is said to be experienced. The continued use of the cigarettes induces sleep, followed by a slight sensation of heaviness in the head. They smell pleasantly of coumarin. In Germany the plant is erroneously known under the name "punaria ascochingae." The dried and powdered whole plant is made into tablets weighing five grammes each and the latter are attached to pieces of wood charcoal and placed on a coal fire. The patient inhales the vapour from the burning tablet, with the result, it is said, that at first a slight cough is induced, but afterwards the respiration becomes deeper and the asthma disappears.

A BAD STARTER.

To the Editor of THE LANCET.

SIR,—I think that "Anxious Guardian" would find that in mathematics, the "Medical Preliminary Examination" of the Educational Institute of Scotland is a much easier examination than that of the College of Preceptors. The offices of the Institute are at 40, Princes-street, Edinburgh.—I am, Sir, yours faithfully,

April 6th, 1908. A MEDICAL STUDENT.

THE "NATIONAL HEALTH" MILK PASTEURISER.

THE construction of this apparatus, though perfectly simple, renders the pasteurising process effective and speedy. It comprises (1) an inner vessel or a milk container; (2) an outer vessel provided with a circular base projecting an inch beyond the body of the apparatus; (3) a shallow conical internal vessel having a double bottom perforated; (4) a second shallow cone for directing the water flow; and (5) a vertical circulating cylinder with openings at the top. The action is as follows. The milk being placed in the inner container the circulator is filled up to the centre of the openings at the top. The burner is started and at once a uniform circulation commences. As the water in the base boils it is forced upwards through the annular space formed by the shallow conical vessel immediately above, and this action is repeated through the second cone which then directs the water flow to the top where it streams through the perforations and descends down the outer surface of the milk container, finally returning to the heating base to go through the same circulatory process again. The object of this circulatory system is to prevent the boiling water from becoming directly mixed with the heated water circulating round the milk in the inner vessel, thus reducing the tendency of the proteins of the milk to coagulate while raising it quickly to the heat required for complete pasteurisation. The action, in short, is that the water surrounding the milk container is kept in rapid circulation by coming into contact with the water in violent ebullition in the ebullition chamber, causing an upward current on the outside of the circulating cylinder and a downward current against the outside of the milk container. The apparatus, which we found to work in complete accordance with these statements, was submitted to us by Mr. W. Lawrence of 19, Brackley-terrace, Chiswick, London, W.

CARE OF FEEBLE-MINDED GIRLS.

THE Birmingham Laundry and Homes of Industry is a society which devotes itself more especially to the protection and care of feeble-minded women and girls. It accomplishes a large amount of good work yet it fails at the critical point, just as all such societies must fail whilst the law regarding the feeble-minded remains unchanged; for the society has no legal control over those who are not capable of judging for themselves and consequently it finds that now and then, when its persuasive powers fail, it is forced to dismiss from its homes certain individuals who long for things which the homes cannot give and whose lives after they leave the homes are sure to lead to disaster both for themselves and the community at large. It is to be hoped that when the report of the Royal Commission appears it will urge the adoption of the only plan with regard to the feeble-minded of both sexes which offers any hope of an ultimately good result.

WANTED—A HOME.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me where a girl of 17 years, the child of epileptic parents, can be taken care of? She is untidy, careless, and wayward; in fact, seems developing the usual symptoms of such cases. The parents are only able to afford a small sum weekly, though they are of the better class.

I am, Sir, yours faithfully,
H. P. GILBERT.

The Elms, Whitley Park, Reading, April 7th, 1908.

CLOTHING EXHIBITION.

AN exhibition was opened at the Royal Agricultural Hall, London, on April 6th, which is officially termed "The First Clothing and Outfitting and Allied Trades Exhibition and Market." It has been organised by the International Trade Exhibitions, Limited, London, and its primary object is to promote commercial relations between buyers and sellers, whereby in a period of ten days may be viewed a collection of productions and manufactures which would ordinarily entail upon the buyer considerable journeying and expense. Although the exhibition is strictly for the wholesale trades referred to the management has decided to open it to the general public each day after 3 P.M. The exhibition remains open until 10 P.M. and will finally close on April 16th.

◆

M. H.—We believe that the institutions in question will carry out treatment as laid down by the practitioner and under the supervision of the practitioner. In this event there is nothing unprofessional in making use of them.

Nemesis does not give us the reference to the case in which he considers that he was hardly treated. We can scarcely imagine it to have been on all fours with the case of Dr. H. F. Stokes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

MEDICAL SOCIETY OF *LONDON*, 11, *Chandos-street, Cavendish-square, W.*

MONDAY.—8.30 P.M., *Clinical Meeting.* Dr. P. Weber, Dr. O. K. Williamson, Dr. F. S. Palmer, Dr. W. H. Willcox, Dr. StClair Thomson, Dr. C. W. Chapman, Dr. S. Thompson, and others: Cases, &c.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. J. Strachan: On Dendritic Growths of Copper Oxide in Paper. Mr. F. Enock: Nature's Protection of Insect Life (illustrated by lantern slides in three-colour photography).

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. C. Gilling: The Constituents of Simaruba Bark (communication from the Pharmaceutical Research Laboratory). Mr. A. Gunn and Mr. R. F. Harrison: The Colouration of Adrenine Solutions. Mr. J. A. Jennings: Historical Sketch of a London Hospital, with a brief account of Hospital Pharmacy (illustrated).

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 20, Hanover-square, W.

WEDNESDAY.—8.30 P.M., Adjourned Discussion on Dr. Prout's paper on the Rôle of Filaria in the Production of Disease. Dr. Prout: On an Unusual Cause of Dysenteric Diarrhœa in the Tropics. Dr. T. P. Macdonald (North Queensland): Tropical Lands and White Races.

INCORPORATED INSTITUTE OF HYGIENE, 34, Devonshire-street, Harley-street, W.

MONDAY.—3.30 P.M., Dr. J. W. H. Eyre: The Beneficent Bacteria—the Part they Play in our Every-day Life.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. M. H. MacLeod: Clinique (Skin).
TUESDAY.—4 P.M., Dr. H. Mackenzie: Clinique (Medical).
WEDNESDAY.—4 P.M., Mr. T. P. Legg: Clinique (Surgical).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. X Rays.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. X Rays. Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. Dr. K. Scott: Diseases of the Eye. 2.30 P.M., Operations. X Rays. Dr. D. Robinson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. X Rays.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. X Rays. Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children, 2 P.M., Medical and Surgical Clinics. Dr. K. Scott: Diseases of the Eye. 2.30 P.M., Operations. X Rays. Dr. D. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Cliniques:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Throat, Nose, and Ear (Mr. H. W. Carson); 4.30 P.M., Lecture Demonstration:—Dr. Pirie: Treatment of Tuberculous Conditions by X Rays.

TUESDAY.—Clinique:—10.30 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Cliniques:—Surgical Out-patient (Mr. Edmunds); Gynæcological (Dr. A. E. Giles).

to in the last part of the question. These regulations are in an advanced state of preparation.

Friday, April 3rd.

Irish Poor-law Medical Officers.

In the course of the debate on the motion for the second reading of the Poor-law (Ireland) Bill,

Mr. Birrell (Chief Secretary to the Lord Lieutenant) said that next year he would do his best to introduce a Bill dealing with the Irish Poor-law administration. He could not assent to the Bill under discussion.

Mr. Hugh Barrie urged that the Bill should be read a second time and sent to a committee. Many of its provisions could be put into operation at small cost. Under it it would be competent for local authorities to give grants in aid of sanatoriums for consumptives. He was in this connexion glad to acknowledge the work done by the Countess of Aberdeen and by the combined efforts of other ladies in different parts of Ireland in endeavouring to check the ravages of tuberculosis.

Mr. Fetherstonhaugh expressed a hope that in their future legislation the Government would deal with the position and status of Poor-law medical officers in Ireland. The conditions under which they were appointed were unsatisfactory. The best men were not always secured owing to the very narrow localism which prevailed in many cases. The conditions under which they served were absolutely fatal to their position.

The Bill was subsequently rejected by 89 votes to 35.

Coroners' Inquests Bill.

Mr. Higham moved the second reading of the Coroners' Inquests Bill. Its purpose is to make the viewing of bodies not compulsory but optional in the discretion of the coroner. He contended that in many cases the viewing of the body was not only exceedingly distasteful to the jury but exposed them to personal risk of infection.

Mr. H. Samuel (Under Secretary for Home Affairs), in assenting to the second reading, reserved to the Government the liberty of proposing amendments at a later stage if they thought fit, particularly in reference to the proposal that the coroner himself should be exempt from the viewing of the body.

The second reading was carried by 118 votes to 45.

Overcrowding in Scotland.

An elaborate return has been presented to Parliament showing the housing conditions of the population of Scotland. In it it is noted that the proportion of the total population living more than two per room has fallen from 58·57 per cent. in 1861 to 45·68 in 1901; that the proportion living more than three per room has fallen from 33·83 per cent. in 1861 to 22·91 in 1901; and that the proportion living more than four per room has fallen from 18·67 per cent. in 1861 to 9·56 in 1901.

Monday, April 6th.

The Medical Examination of Engine-Drivers.

Mr. Lonsdale asked the President of the Board of Trade whether he had considered the report of Lieutenant-Colonel Yorke that the collision on the London and North-Western Railway near Atherton station was due to the debilitated condition of the driver, and to the fact that he was in the last stage of a fatal complaint; and whether he intended to take any measures to secure the more frequent medical examination of engine-drivers.—Mr. Lloyd George replied: I am already in communication with the principal railway companies on the subject of the medical examination of engine-drivers, and I am calling their special attention to Colonel Yorke's report on the accident near Atherton.

BOOKS, ETC., RECEIVED.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Allan, H. W., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Inspector of Schools for the Wells District of Somerset.

Baird, Harvey, M.D., Ch.B. Edin., has been appointed Assistant Medical Officer at the Cardiff Mental Hospital.

Browne, Francis James, M.B., Ch.B. Aberd., has been appointed Surgeon to the Powells Tillery Collieries, Abertillery (Mon.).

Caldwell, M. F., M.B., B.Ch. Irel., has been appointed Junior Assistant Medical Officer at the Cardiff Mental Hospital.

Downes, Harold, M.B., L.R.C.P. Edin., has been appointed Medical Superintendent to Benenden Sanatorium.

Edwards, William Lloyd, L.R.C.P. Lond., M.R.C.S., D.P.H. Lond., has been appointed Assistant Medical Officer of Health and Medical Inspector of School Children by the Barry (Glamorganshire) District Council.

Forde, T. A. Munro, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Senior Surgeon to the Royal Hospital, Portsmouth.

Griffiths, Evan John, M.B., Ch.B. Edin., has been appointed Medical Officer for the Inspection of School Children by the Pontypridd Education Committee.

Hebblethwaite, A. G., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Physician to the Keighley Victoria Hospital.

fair to say that there is also a smaller and much less definite series of lamellæ which pass from the inner and posterior part of the head to the front part of the neck.

FIG. 3.

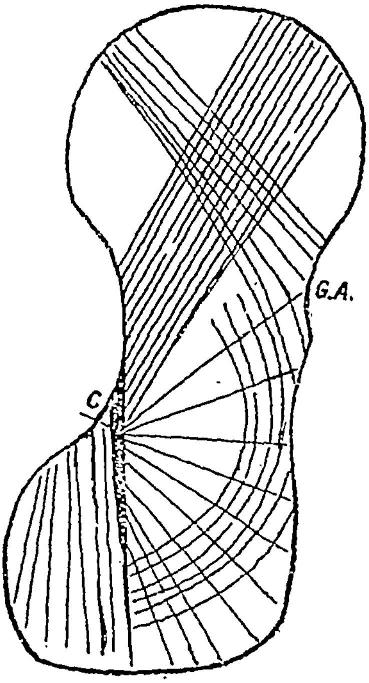

Diagram of section of upper end of femur cut parallel with long axis of neck, showing arrangement of lamellæ which counteract back thrust through head of femur. G. A., Groove for anterior ligament. C., Calcar. Scale life size.

The first and more important series are the same as the lamellæ which are described as passing from the upper and inner portion of the articular surface of the head to the under surface of the neck, but viewed in a different plane. This series therefore lies in an oblique plane and passes from within downwards, outwards, and backwards. They are very definite in this specimen of bone, and as they are the same as the lamellæ which pass from the upper part of the head to the lower surface of the neck, which all authorities agree transmit pressure, they obviously transmit pressure, not only from the upper and inner part of the head but also from its anterior part. We may therefore conclude that pressure is transmitted through the upper, inner, and anterior part of the head of the femur to the posterior and inferior surface of the neck. Now this series of lamellæ help to explain four conditions which are met with: the first, an anatomical structure; the second and third, pathological conditions; and the fourth, a condition due to traumatism. The first is the "calcar femorale," the second the deformity known under the name of coxa vara, the third the triangular acetabulum associated with old unreduced dislocated hips, and the fourth the line of fracture in typical intracapsular fracture of the neck of the femur. These oblique series of lamellæ which pass into the posterior surface of the neck, which is formed of thick compact tissue, pass in over a distance of about five-eighths of an inch, and, externally, some pass into the anterior surface of the calcar femorale.

Now, although one must regard these lamellæ as pressure lamellæ, yet it is not generally recognised that therefore pressure which is transmitted from the trunk to the lower limbs passes not only through the upper part of the head of the femur but also through its anterior part. Now, these three specimens, representing that degenerative process known under the name of osteo-arthritis, show distinctly that the eburnated remnant of the articular surface of the head looks in a direction not only upwards and inwards but also forwards. It is therefore evident that the chief pressure in these bones has passed through the upper and anterior part of the head of the femur; and therefore these specimens afford ample proof that the pressure is transmitted along the oblique series of lamellæ which pass to the posterior surface of the neck in the region of the calcar femorale. The function of the calcar is usually said to be that of transmission of the lines of pressure from the head and neck to the shaft of the femur. This is very probably correct, but only partially so, and no explanation of its relatively posterior position has yet been offered. By a reference to the oblique series of pressure lamellæ its position and function are rendered clear. Not only does it transmit the lines of pressure falling on to the posterior surface of the neck, but it also enormously increases the strength of the neck. And for this reason: Suppose that in the diagram (*Fig. 3*) the chief lines of pressure pass above and behind the centre of rotation of the head of the femur, then there is a tendency for the great trochanter to be pushed forwards, and this tendency to swing forwards is restrained by the attachment of the external rotator muscles of the thigh and the pull of the tense posterior part of the capsule of the hip-joint. Thus there is a tendency for the great trochanter to be bent backwards, a tendency which is very much diminished by the presence of the calcar femorale. If *now a further examination of the sections of bone cut parallel with the long axis* of the neck be made, *the bony lamellæ which are seen behind the calcar are found to pass out more or less parallel with* the calcar to the outer surface of the great trochanter. They are intersected by transverse fibres and these lamellæ in the adult bone make up coarser cancellous tissue than elsewhere. If, however, the lamellæ in front of the calcar be examined they will be found to contain much finer meshes and can be divided into two series intersecting each other at right angles, one radiating outwards and forwards from the front part of the calcar femorale and its continuation into the outer compact layer in the trochanteric region, and another series curving forwards and inwards and passing not only into the anterior surface of the neck of the femur but also passing into those lamellæ which I have previously described as passing from the posterior and upper surface of the head to the anterior surface of the neck. The former are lamellæ which transmit pressure from the calcar to the anterior surface of the great trochanter and neck; the latter are tension lamellæ. Now, although the calcar femorale may be very definitely studied in this manner and its function, namely, of not only transmitting lines of pressure from the neck to the shaft but also of preventing bending backwards of the neck, and to displacement backwards of the great trochanter, which is really a rotation backwards, be demonstrated, yet its position may be still better displayed in a method which I shall describe later. The position of the calcar is therefore chiefly concerned with the tendency of the neck of the femur to be bent and enormously increases the strength of the neck. The calcar is developed in connexion with the development of the oblique series of lamellæ which pass from the inner, upper, and anterior part

Notes, Short Comments, and Answers to Correspondents.

THE ZAKKA KHEL EXPEDITION.

WE are indebted to a well-known member of the profession for the following interesting letters from his son, an officer in the Indian Medical Service:—

Bazar Valley, Field Force, Feb. 17th, 1908.

Well, here I am in the enemy's country. I got up to Peshawar early last Thursday morning, Feb. 13th, and was told I was very late as the force had started that morning. I was given orders to go on at once in a cart, taking nothing with me but my bedding and a change of clothing, and that if I did not go at once I should not catch them up, so I could not wait any time and in consequence came with practically nothing and no pony. What I forgot to put in in my hurry was an extra pair of boots and as this is awful country I am afraid mine will last no time. I don't know what I shall do. I am attached to a Field Hospital. The first day we marched to Jamrud at the entrance to the Khyber Pass and the next day to a place Ali Masjid in the middle of the pass. The next day we separated from our brigade which came on in front and had a good deal of fighting. Then yesterday we came on to join them. There was a little fighting and all last night they were sniping at us. I dug myself into a trench and heard a few bullets. To-day we have had a quiet day in camp. A few parties were sent out and there was a little firing but not much. We were jolly glad of a quiet day. At present no one seems to know what is going to happen. We are encamped in one of their villages, two of which we have destroyed. They have about three more. At present I fancy we will take one of those which is the biggest and destroy that and then, perhaps, after that get out or perhaps destroy the lot. Two of their chiefs came into camp this evening; of course, one doesn't know what it means. Probably only to find out our position, &c., really. The other brigade is about five miles behind us. I fancy they are coming up to-morrow and they will probably then be given their chance. Some people seem to think the whole thing will last only about a fortnight. In that case we probably shall not get a medal which will be bad luck. We have only had a few casualties, two men killed and three badly wounded. One has to rough it a good bit and our food is not exactly delightful but we do not do badly. I have no time to write more.

Peshawar, March 3rd, 1908.

By the address you will see we are back again from the Bazar Valley. I will try and write you an account of the whole show, as up to now I have not been able to write much, as in the first place I did not know much about what was to happen, &c. I dareay you have read a little bit about it in the papers.

First of all the cause of the expedition. This was due to raids on Peshawar by the Zakka Khels. The Zakka Khels are one tribe of the Afridis and live in the Bazar Valley which is the other side of a range of hills surrounding Peshawar.

They had several times raided Peshawar city by night and killed a man or two and carried away booty. Their last and most daring raid was the one which really gave rise to the expedition. They came into the city by night, disguised of course, and carried out their work by means of pretending a marriage ceremony was in course of progress. At these ceremonies in this country apparently they make a great noise, beating drums, &c. Well under cover of this noise they broke into several shops, killing any who attempted to stop them, and went off with a lakh of rupees (£6666). The police did not attempt to interfere, thinking it was only a marriage ceremony. Well, after that it was decided to punish them and they were only waiting for permission from the Home Government. The whole plan was to take them by surprise and everything was kept very secret. We started off on the morning of Feb. 13th and marched to Jamrud, which is just outside the Khyber Pass at the beginning, about 10 miles from Peshawar. Our force consisted of two brigades made up as follows, General Sir J. Willcocks in command of the whole:—

1st Brigade (General Anderson).—Warwicks, 2nd Battalion 5th Ghurkas, 59th Rifles, 53rd Sikhs, 1 Mountain Battery, No. 101 Native Field Hospital.

2nd Brigade (General Barrett).—Seaforth Highlanders, 45th Sikhs, 54th Sikhs, 28th Punjabis, 1 Mountain Battery, 1 company sappers and miners, No. 102 Native Field Hospital.* (* This is where I was.)

We stopped at Jamrud the night of the 13th and proceeded next day to Ali Masjid through the Khyber Pass. The Khyber Pass begins at Jamrud, it proceeds to Ali Masjid and here breaks off into two different paths, one goes to Landi Kotal and into Afghanistan, the other to Chora Kotal, where it enters the Bazar Valley. The road was good as far as Ali Masjid where we camped on the 14th. On the 15th we moved off in two parts, the 2nd Brigade going ahead without baggage and with two days' rations. Two out of the four of us went with them and the other two stopped behind with the 1st Brigade and baggage. The other party consisting of the 1st Brigade, the baggage of both brigades and the field hospitals moved off about two hours later and got into the Bazar Valley and reached Chora, a village belonging to a friendly section of the Zakka Khels and which had been handed over to the troops at once. Here we camped for the night. The 2nd Brigade which had gone on in advance after leaving Chora had a stiffish time, and were fighting the whole day and night. The reason probably that they were not attacked before reaching Chora was that we came in so quickly that the Zakkas had no time to do more than get their wives and families into Afghanistan.

On the next day, the 16th, the rest of the field hospital with which I was were ordered to go on and rejoin the 2nd Brigade and also take on their baggage. We caught up with them just before Walai, which village they then proceeded to take and destroy. We then encamped on that site, which was our headquarters for the rest of the campaign. We had hardly got into camp when we were again attacked from a high hill near the camp. The 45th Sikhs and Seaforth Highlanders were sent to take the hill, which they did, two men of the 45th being severely wounded with broken thighs. That night pickets were put on all the surrounding hills, but during the night they were attacked and some of the Zakkas must have got between them and shot into camp. On the 17th we had a rest during the day; at night there was again a good deal of shooting into camp, which continued most of the time we were there, though it rather slackened off towards the end. On the 18th a force was sent to attack and destroy China, the capital of the Zakkas. I went with them. We took it fairly easily and blew up their fortifications till about 3 o'clock, when we returned to camp. As we were returning they came up behind us, following up quickly, and we had a good many men hit before the last got back into camp.

The 1st Brigade came up to Walai that day and joined us, with the exception of one regiment and the other field hospital, which were left at Chora.

On the 19th the 1st Brigade went out to finish the destruction of China, which they did without any loss, and on the 20th they finally razed it to the ground. On the 21st the greater portion of both brigades went right to the end of the valley to a place, Halwai, which they destroyed and returned to camp fairly early, though a good many men were wounded on the return journey. On the 22nd the 1st Brigade went out and destroyed a small village near Walai. The 23rd was a slack day. On the 24th another small village was destroyed. On the 25th a jirgah or council of the tribes round about came into the camp to try and stop the proceedings. General Willcocks talked to them and it was understood that they were to interview the Zakkas and bring their head men into camp to discuss conditions. They were given two days for this. During this time we did nothing. On the 28th the jirgah returned with the Zakkas, about 1000 altogether. They sat and discussed and the terms were agreed to. The terms were that they were to be of good behaviour, to punish the raiders on Peshawar, 60 rifles were taken from them which are to be returned when the political agent is of opinion that the raiders have been sufficiently punished, and that they were not to molest us on our retiring from the country.

We left Walai on the 29th and the 2nd Brigade marched straight through to Ali Masjid, the 1st Brigade stopping at Chora. The next day we marched to Jamrud and the 1st Brigade doing a double march joined us there, and yesterday we all marched back to Peshawar, which we reached about one o'clock. The regiments went into camp and marched to their various stations, except those that came from Peshawar.

We, the field hospital, went to an old hospital here and dumped down our boxes of medicines, hospital tents, &c., and had to wait till to-day for a receipt of their correctness. We all four came to the Dak bungalow for the night. A Dak bungalow is a bungalow provided by Government for travellers. It contains a cook and bed, chair and table, and one stops there, bringing all one's kit.

We had some snow and rain the whole of one day and night just before we left Walai, and as one is in the open it was distinctly unpleasant. I had made a small tent out of tarpaulins and that kept me fairly dry at night.

The worst part of the whole show was the dirt. I did not change my clothes the whole time and slept in them at night. I slept in a pit dug in the ground and the soil used to drop on me and into my bedclothes. The feeding, too, was not too good, but we did not do badly on the whole, because we took out a good many tins of different articles, jam, &c., and every second day we got fresh meat from the commissariat after the first week.

I am going back to Bareilly to-night and will finish this there.

March 5th.

I arrived at Bareilly at 3 A.M. this morning. I find my place has not been filled up and so I hope to stop on here for some time. I may possibly not be moved till the hot weather is over. I have got back into my same rooms, but have a new bearer, as my last one ran away on the way up to Peshawar. It is much hotter here than in the Bazar Valley. I stayed a day at Peshawar. I went into the city there and made a few purchases. It is *the* place to buy carpets and all the finest come there from Persia—i.e., the old ones. I have been the whole day getting my room straight, as I had packed all my things. I received your letter to-day which reached here last Sunday. They did not send it on I am glad to say. I am very fit after my campaign.

BRACHYCLADI STUCKERTI.

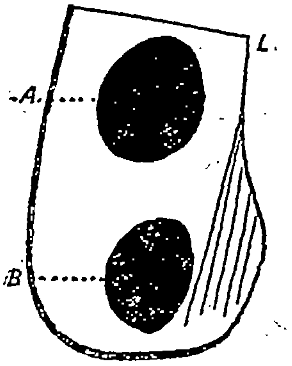
IN the *Pharmaceutical Journal* of March 7th, Mr. E. M. Holmes contributes an interesting article on Brachycladi Stuckerti, a South American plant which has been employed by the natives of Argentina for the mountain affection known locally as "mal de puna." In asthma the continued use of an infusion of the

Now I must beg your leave to digress for one moment whilst I go a little more in detail into the question of the movements of the hip-joint which are concerned with this variety of fracture. When the hip-joint is disarticulated the anterior surface of the neck comes much more readily into contact with the anterior and upper part of the rim of the acetabulum than do the corresponding posterior parts of the same portions of bone. This may be due to the different shape of the anterior and posterior surface of the neck of the femur and the greater concavity of the posterior surface of the neck than on the anterior surface of the neck. Now, although these points are undoubtedly true in the disarticulated joint, yet from a careful examination of the undissected joint it is clear that another reason why the posterior surface of the neck does not come into contact with the corresponding portion of the acetabulum is that the very strong anterior ligament or Y-shaped ligament of Bigelow prevents it. Now, the posterior part of the capsule of the joint is nothing like so strong and certainly would not offer any marked resistance to the internal rotation of the hip-joint. But a structure which has been much abused because it is very rarely absent and very occasionally atrophied, is, I venture to think, responsible to a certain extent for diminishing the amount of internal rotation, flexion, and adduction, and thus preventing the anterior surface of the neck from coming into contact with the corresponding portion of the acetabulum; and this structure is the "ligamentum teres" of the hip-joint. This is considered by many anatomists to be a useless structure. It is curious that out of the 150 hip-joints that I have opened I have in only one case found a ligamentum teres atrophied and easily ruptured. Moreover, it is put on the stretch just when the limb is internally rotated and adducted, as well as flexed, and it is therefore clear that the function of the ligamentum teres is to prevent undue contact taking place between the anterior surface of the neck and the corresponding portion of the acetabulum. It is not quite fair, I think, to say because it is occasionally absent that therefore the ligamentum teres has no function. Absence, in the case of the tibia, is not brought into account when the question of the function of this bone is being considered. Authorities may say that the ligamentum teres is an atrophied part of the pectineus. Then one may ask the question, Why, if it is useless, has it remained at all? The ligamentum teres, therefore, tends to prevent this anterior surface of the neck of the femur from coming into contact with the acetabulum.

We may now go back to the question of intracapsular fracture of the neck of the femur and we may assume that the pressure starts from the front of the upper part of the neck. Now, if the patient be in the flexed position when the accident happened, the ligamentum teres is not strong enough to resist the sudden force which is put upon it and so it may be either stretched or ruptured. The anterior surface of the neck of the femur then comes into forcible contact with the corresponding part of the acetabulum and the fracture is begun (Mr. Arbuthnot Lane). The line of fracture then passes for some distance in a transverse direction along the neck until it meets with these lamellæ coming down from the anterior upper surface of the head of the femur to the posterior and under surface of the neck of the same bone, and is by them deflected so as to form either a posterior or an inferior tongue of bone. But an explanation must also be found for a similar injury which happens where the patient says that he made an effort to recover himself and then felt something go. Now, in the effort to recover oneself one naturally hyperextends the hip-joint and more tension is put upon the strong anterior ligament of the hip-joint, with the result that it is forcibly stretched over the neck of the femur, close to the head of that bone. Now, if we make an obliquely transverse section of the head, neck, and trochanteric region of the femur we shall find that the compact tissue lying at the bottom of the groove or impression on the neck of the femur against which the anterior ligament is resting is very thin and therefore presumably easily liable to fracture. And therefore one may conclude that in the hyperextended position of the limb, such a position as is taken up when a patient attempts to recover himself from falling—that in that position, I say, the anterior ligament of the hip-joint is in part responsible for intracapsular fracture of the neck of the femur.

It is often said that the line of fracture in intracapsular fracture of the neck of the femur occurs at the weakest spot in the neck. This weakest spot is presumably at that place where most degenerative fatty changes are found—i.e., half way along the neck, where indeed a mass of fat may be found between the main series of lamellæ, spherical in shape, and as much in some cases as half an inch across. Now, although fracture may occur through this spherical mass, yet in most cases (Fig. 6) apparently the line of fracture runs nearer the head than this, and therefore we may assume that in many cases at any rate the position of the line of fracture is not dependent only upon the structure and degeneration of the bone but also upon external influences as well, such as, for example, the rim of the acetabulum and the anterior ligament of the hip-joint. It has been asserted that the absence of the calcar femorale is responsible for the occurrence of intracapsular fracture. That this statement is very probably correct there is no doubt, but it is because the calcar enormously increases the strength of the neck not so much in transmitting vertical pressure, as by its power to prevent bending of the neck, as we have seen, backwards or forwards. I have here a specimen showing the association of an intracapsular fracture and a calcar femorale.

FIG. 6.



Transverse section of distal fragment of intracapsular fracture showing fatty patches A. and B. Note that line of fracture L. does not pass through A.

Now, although the results of intracapsular fracture of the neck of the femur are known thoroughly, still it will not be out of place, I think, just to refer to these two specimens, one taken an unknown time after the injury, the other removed four years after the accident. And it will be noticed that there has been a complete atrophy in this second specimen, not only of the neck but also of a great part of the upper portion of the shaft of the femur. Now, although one can have few remarks to offer upon the question of treatment, I would venture to quote one case which, by the kindness of Mr. C. J. Symonds and Mr. L. A. Dunn, I was enabled to operate upon. A man sustained an intracapsular fracture of the neck of the thigh bone and extension was applied both in a Hodgen's splint and with plaster of Paris. The hip remained stiff and gave him so much pain that it was impossible for him to walk about without two crutches. He eventually consented to have the head of his thigh bone removed, and though the wound did not heal up altogether kindly still it did eventually heal up, and healed up completely. Since that time the man has recovered the use of his limb. He only uses a stick to move about with and, above all, he has lost his pain. I shall not have time to go into this question in full, but it is certainly a treatment which might be adopted with advantage in many of these cases of ununited intracapsular fracture of the neck of the thigh bone.

We must now go into the question of extracapsular fracture of the neck of the thigh bone. And in this connexion it is important to know that there is a primary line of fracture which is the true extracapsular fracture, and that this line of fracture separates a portion of bone formed of the head and neck of the femur. This portion of bone (Fig. 7) which is separated bears a remarkable resemblance to those tools which are used by masons and slaters for the purpose of cutting bricks and slates. They have a broad head, a narrower neck, and a broader blade. They are known as bolster chisels. The resemblance is still further increased when we consider that these chisels frequently have at one end of the blade a sharp point. I think when I hold up this specimen and

The Hunterian Lectures

ON

THE ANATOMY OF THE LONG BONES RELATIVE TO CERTAIN FRACTURES.

Delivered before the Royal College of Surgeons of England on March 9th and 11th, 1908,

By RALPH THOMPSON, Ch.M. Vict.,
F.R.C.S. Eng.,

ASSISTANT SURGEON, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA;
DEMONSTRATOR OF ANATOMY, GUY'S HOSPITAL; HUNTERIAN
PROFESSOR, ROYAL COLLEGE OF SURGEONS
OF ENGLAND.

LECTURE I.

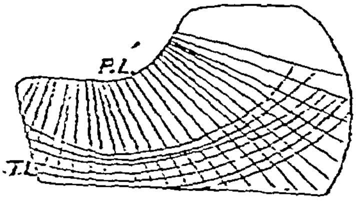
Delivered on March 9th.

Mr. President, Ladies, and Gentlemen,—Although much work has been done in connexion with the general and local pathological conditions which predispose to fractures of the long bones, yet perhaps sufficient attention has not been paid to their exact anatomy, especially as regards their internal structure. It was not without much hesitation that the subject of the two lectures, which I have been called upon to deliver in this College was chosen, and when one reflects that it is frequently said that anatomy is a limited subject and that no new discovery can be made in it, this hesitation must be excused. Moreover, so many great names have been, and still are, associated with the question of fractures, that there seems little to say concerning a subject about which Hunter, Astley Cooper, R. W. Smith, and Bennett have written and spoken. There seems still less to say concerning a subject which has been dealt with so thoroughly and successfully by x ray photographers. But, Sir, the preface to your work on the anatomy of joints has encouraged me to proceed with the subject, and, after all, so long as the cause of any fracture in any individual remains unknown, so long is there room for, at all events, some reflection as to the exact cause of a particular fracture.

I propose to deal with fractures of the long bones, but as the anatomical conditions governing the results of these fractures cannot be considered without a reference to ligaments I shall have no hesitation in raising the question of the functions of certain important ligaments.

In the ends of the bones of an ordinary adult man there are developed definite lamellæ running in the main direction along which pressure is transmitted. Certain other lamellæ are also developed gradually crossing these pressure lamellæ at right angles. These are known as tension lamellæ. Their presence generally increases the elasticity and therefore the strength of the bone. (Fig. 1.) In the young person as well as in the old these pressure lamellæ are not well seen, nor are the tension lamellæ. In the young person the cancellous tissue at the ends of the long bones is so dense and the meshes are so fine that the pressure and tension lamellæ can hardly be demonstrated. In the old person the bone fibres are so obscured by the presence of fat that they are very difficult to discover. Although the fat is deposited generally in the substance of the cancellous tissue, yet it is apt to occupy certain definite positions and to occur in relatively large masses. For example, such definite masses may be found in the lower end of the radius, the upper end of the humerus, the inner end of the clavicle, and the upper end of the femur. In the tibia, too, a small mass of fat is developed at the root of the internal malleolus. These masses of fat appear to develop in the part of the bone which is least subjected to pressure. In the case of the clavicle and the femur as well as the upper end of the humerus they appear to develop between definite series of lamellæ.

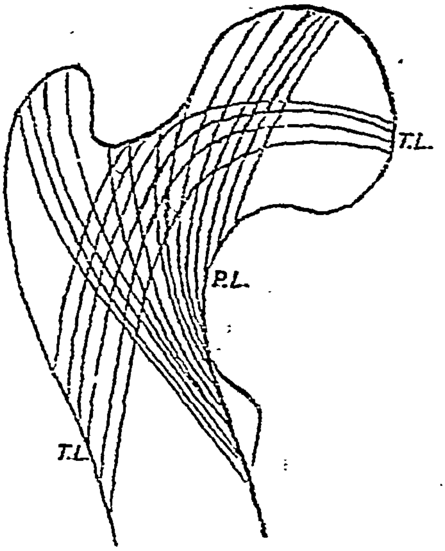
Fig 1.



Showing pressure and tension lamellæ in os calcis. P. L., Pressure lamellæ. T. L., Tension lamellæ.

I propose in my first lecture to deal with fractures of the neck of the thigh-bone. I shall first endeavour to show from recent specimens that these fractures have perfectly definite causes, the statement of which depends to a large extent upon the knowledge of the internal structure of the upper end of the femur. A study of the internal structure of the upper end of the femur throws such a flood of light upon certain deformities that I shall have no hesitation in referring also in some detail to the conditions met with in coxa vara and in old unreduced dislocations of the hip-joint. The usual conception of the internal structure of the upper end of the femur is that which is gathered from a coronal section such as this (Fig. 2). Now in this section is shown a series of arching lamellæ passing from the inner and outer surfaces of the shaft of the femur into the trochanteric region, the neck and the head. Those from the inner surface pass upwards into the region of the great trochanter and also into the lower part of the neck and so by additional series of lamellæ to the upper surface of the head. Those lamellæ from the outer surface pass also upwards into the great trochanter and then *viâ* the upper part of the neck of the femur to the lower portion of the head of the same bone. Now there are a series of lamellæ which do not thus form an arch and which pass from the upper surface of the head to the lower surface of the neck and thus to the compact layer on the inner surface of the shaft of the femur. The spur of bone which is represented in this obliquely transverse section of the upper end of the femur and which is known as the calcar femorale, or Merkel's, or Adams's arc is said to lie in the lines of pressure passing from the head and neck to the shaft of the bone. In order to study this spur of bone transverse sections are frequently made of the upper end of the femur, but such a section gives little indication of its position and none of its true function. Its position and function may be made out in a much more satisfactory manner by the reference to sections which are obliquely transverse—that is, parallel with the long axis of the neck. (Fig. 3.) These sections show, in addition to the calcar the position of which will be referred to later, a most important series of lamellæ passing from the anterior and inner part of the head of the femur to the posterior surface of the neck. These are very definitely shown in many sections which have been made; but it is only

Fig. 2.



Showing chief series of lamellæ in coronal section of upper end of femur. P. L., Pressure lamellæ. T. L., Tension lamellæ. Scale life size.

surface of the neck, just beneath the groove for the obturator externus tendon on its way to the digital fossa, and terminating below by gradually fading away into the compact tissue of the shaft of the femur, underneath and external to the upper part of the spiral line. Roughly, it may be said to extend from the base of the great trochanter to the lowest part of the base of the lesser trochanter. The calcar is half an inch deep or more in its deepest part, which is just above its centre, and its edge lies at the junction of the posterior and middle thirds of a line drawn between the anterior and posterior surfaces of the neck of the femur. The outer edge varies in position according to the depth of the calcar. It may be continuous with fine laminæ of bone running nearly parallel with each other towards the compact layer of the outer surface of the upper part of the femur. The calcar is said to disappear in old age, but I have collected specimens showing a well-marked calcar in males aged 70, 71, 80, and 87 years; and in two females aged 65 and one aged 83 years. In the case of the male aged 87 years the calcar is well seen in the right femur, of which there was an unimpacted extracapsular fracture, and there is also a good calcar in the left femur removed from the same case. The calcar was not present in any femur of any fœtus or young infant which I have examined, but there was a calcar present in three male subjects aged three years each and in one female aged six years. The calcar was not found in two subjects, aged 21 and 27 years respectively, the former a female and the latter a male. The deposition of fat in the region of the neck of the femur may also profitably be considered here (Fig. 8). As age advances fat is deposited in two places in considerable quantity, forming a large globular mass at least half an inch in diameter. One of these masses of fat lies in the narrow part of the neck, about its middle. The other mass lies in front of the anterior surface of the calcar. The former deposit may possibly predispose to intracapsular fractures of the neck of the femur; the latter deposit of fat to the splitting of the upper end of the femur described in connexion with extracapsular fracture. For in this case fat offers less resistance to the impaction of the fragment of head and neck separated from the rest of the bone. A reference to sections passing through the neck of the femur in young adults shows that the cancellous tissue is much denser than in old people, and therefore we may expect that if a fracture through the base of the neck occurs in young people, then the calcar femorale will not form such a dangerous weapon as in old people in whom fat is deposited.

There are now two difficulties to be considered in connexion with the production of the secondary vertical fracture by the calcar. The first is, that the splitting is much longer than the calcar. This may be explained by referring to the fact that the splitting which a chisel may produce is frequently much longer than the blade of the chisel itself. Another difficulty is that while the calcar runs downwards and forwards, the vertical fracture runs downwards and backwards. In many cases, however, of fracture through the neck of the femur flexion of the lower fragment is a marked clinical and anatomical feature. Flexion of the lower fragment brings the calcar exactly opposite to, and parallel with, the vertical line of fracture which is produced. It is generally agreed that the calcar lies in the lines of pressure transmitted from the head to the shaft of the femur. I have, I think, also proved conclusively that it has an additional function to this and probably a more important function—i.e., to prevent the natural tendency to curvature forwards or backwards of the great trochanter. Now, whilst it is denied by authorities that impacted extracapsular fracture follows upon falls on the feet, yet it is possible that such a condition might occur. In such a case, the lower fragment being forced upwards by the fall, and dragged inwards by the tonic action of muscles and the upper fragment tending to rotate on an antero-posterior axis, the outer edge of the head and neck—that is, the blade of the chisel—is carried upwards and cuts the trochanter and upper part of the shaft of the femur.

The conclusions arrived at may thus be briefly summarised with regard to the calcar. It does not invariably disappear in old age. It is not invariably present, even in young people. The calcar in extracapsular fracture of the neck of the femur is responsible for the edge and lower end of the chisel, whose other parts are represented by the head and neck of the femur. The calcar certainly produces the vertical secondary fracture of the great trochanter and upper part of the shaft of the femur and may be held partially responsible for the horizontal secondary fracture near the base of the great trochanter.

Varieties of Extracapsular Fracture.

Three well-marked varieties of extracapsular fracture may be classified anatomically. This classification is dependent upon the secondary lines of fractures which I have described. There is also an associated condition rarely present—viz., a transverse fracture of the upper end of the femur. Thus the simplest condition is in those cases where a quadrilateral portion is separated from the posterior part of the great trochanter—i.e., where there is the transverse secondary line of fracture and where there is only the upper portion of the secondary vertical line of fracture. The second condition, which is perhaps commoner, is where the vertical secondary line of fracture is fully developed as well as the transverse line of fracture. The third condition is where the vertical line of fracture only is produced and so a large portion of the great trochanter and shaft is detached as a single piece. In the first and third variety only a single piece is broken off; in the second variety two pieces at least are broken off from the shaft of the bone. In this specimen, however, where there is only a single quadrilateral piece broken off, a tendency to a production of a complete secondary vertical line of fracture is shown by a crack running through the shaft of bone exactly in the same position as that portion of the line of the vertical fracture which runs upwards and inwards to join the primary line of fracture. It is evident, therefore, that the rotation backwards takes place immediately after the primary fracture, and so the transverse secondary fracture has been produced which has arrested the completion of the vertical secondary fracture, the production of which has, however, begun. A fourth variety of which I have a specimen, and for which I can give no adequate anatomical explanation, is where the typical extracapsular fracture is somewhat obscured by a transverse fracture of the upper end of the shaft of the femur.

Results of Extracapsular Fracture of the Neck of the Thigh-bone.

I have, thanks to the kindness of the surgeons of Guy's Hospital, especially Mr. R. C. Lucas, Mr. C. H. Golding-Bird, and Mr. C. J. Symonds, been able to collect a few cases of extracapsular fracture, the after-histories of which are accurately known. In most of the cases there is some obvious deformity, and even in the most favourable cases—I mean those which show no external rotation and in which movement is free—there is at least an inch shortening. The great trochanter is displaced one inch above Nélaton's line. The shortening, therefore, in these cases is due to a diminution which the angle makes with the neck. Now, if the process of disimpaction be adopted as treatment or not, it will be clear that the upper fragment cannot be controlled by any form of treatment, except, of course, in those cases in which an open operation is performed. The usual treatment adopted, or rather a common form of treatment, is that in which extension is applied by means of a Liston's long splint. Now, if the thigh be kept parallel with its fellow and with the main axis of the body, and if disimpaction be adopted, one perhaps cannot cavil at the treatment, but if it be adopted great care must be taken to see that the lower fragment is not only rotated and extended but also forcibly abducted so as to release the impaction downwards and outwards of the base of the neck. If disimpaction be not practised, then extension should be made with the thigh in the abducted position, so as practically to counteract the tendency of the angle between the neck and shaft to diminish. Another form of treatment which has for many years, thanks to the advocacy of Mr. Golding-Bird, been adopted at Guy's Hospital is that by extension with the aid of Hodgen's splint. Now there is one disadvantage about a Hodgen's splint and it is this—that it keeps up of necessity the flexion of the lower fragment, which is a common condition, and unless the treatment be preceded by disimpaction this is a disadvantage.

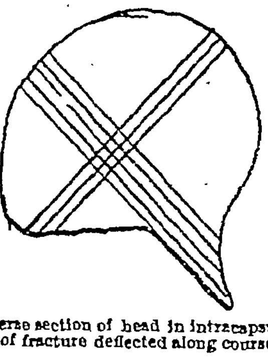
I have, I think, shown that the internal structure of the upper end of the femur plays a great part in explaining certain deformities of the neck, in enabling us to deduce the cause of fracture in intracapsular fracture of the neck of the thigh bone and also what a great part it plays in the mechanism of extracapsular fracture of the thigh bone. Now, although numerous attacks have been made upon the names "extracapsular" and "intracapsular," and although the term "extracapsular" as applied to these of the head of the femur to the posterior and under surface of the neck.

Although the calcar femorale, considered in its function of preventing bending of the neck, is unique in its size, it is interesting to note that there are other well-marked bars or bolts found in a different part of the femur, thrust as it were into the substance of the bone, and which obviously restrain a tendency of the portion of bone in which they are situated to be bent. In the lower end of the femur, the rotatory movements of which are checked by very strong ligaments, quite obvious transverse bars of bone are found in transverse sections, passing from the bottom of the intercondyloid notch into the substance of the internal and external condyles, as indicated in *Fig. 4*, and demonstrated in specimens which I have cut. At their origin these bars may be collected together so as to form a small spur.

In the second place, these oblique lamellæ explain the rotation backwards of the great trochanter occurring in some cases of coxa vara. Now, supposing that the pressure be transmitted behind and above the centre of rotation of the head of the femur in the acetabulum, as has been before pointed out, it is clear that there is a tendency for the great trochanter to be rotated forwards. But it must always be remembered in connexion with the deformities of bone that one cannot consider the bone alone but must also take into account the attachment of muscles and of ligaments. So here the tendency of the great trochanter to rotate forwards will be restrained by the attachment of the external rotator muscles of the thigh in the region *of the digital fossa* and by the posterior part of the capsular ligament of the hip-joint. *Clearly*, therefore, if the bone be rendered weak, either by disease, such as rickets, or injury, such as a separated epiphysis *of* the head of the femur, or a greenstick fracture of the neck of the femur, there will be a tendency for the great trochanter to be rotated backwards. Hence the backward *displacement of the trochanter* occurring in many cases *of coxa* vara, and in this specimen of impacted intracapsular fracture from the museum of this College will be easily explained. On the other hand, supposing that the pressure lies in front of the centre of rotation of the head of the femur in the acetabulum, then there will be a *tendency* for the great trochanter to be swung backwards. But this tendency will be *restrained by the attachment* of the anterior part of the capsule of the hip-joint, and so the great trochanter will be bent forwards. Therefore, a knowledge of those lamellæ is important in connexion with the deformities associated with the condition of coxa vara. They also serve *to* explain the cause of the triangular acetabulum in cases of old-standing dislocation of the hip, for the pressure which is transmitted through the upper and anterior *part of* the head of the femur will also be transmitted through the upper and anterior part of the acetabulum, therefore when the head of the femur is dislocated the upper and anterior lip of the acetabulum will be crushed *down* on to the posterior and lower lip of the same cavity, with the result that a *triangular* acetabulum will be produced. I have here three specimens showing (1) the normal circular acetabulum; (2) a flattened acetabulum in a case of old-standing chronic disease of the hip-joint, which is, you will observe, flattened from above downwards and backwards; and (3) a triangular acetabulum in which the head of the femur had rested *in its* new socket for a period of over *40* years. But whilst these oblique series of lamellæ give us an indication of the cause of coxa vara and of the triangular acetabulum of old dislocated hip-joints it also offers, I venture to think, a very reasonable explanation of the cause of fractures of the neck of the thigh-bone which lie within the capsule of the joint.

The line of fracture in intracapsular fracture passes as a rule from the anterior surface to the posterior surface. It begins about one-eighth *of an inch* from the articular surface of the head in front and passes backwards transverse to the long axis of the *neck for* a distance of two-thirds of the total thickness of the neck; it is then deflected along the oblique series of lamellæ which I have described. Now in that situation in which the line of fracture begins in front is situated the groove for the anterior ligament of the hip-joint, the position of which is indicated in this diagram. I have here two specimens which throw a great deal of light upon the mechanism of this fracture. This single diagram (Fig. 5) may be considered to represent a section of bone in two planes. It may represent, on the one hand, the common line of fracture which is well shown in specimens in the *Museum* of this College and in the London Hospital Museum, and which runs from above *downwards* and outwards, or it may represent an obliquely transverse section of a fracture made parallel with the long axis of the *neck of the femur; so that in the first place* this tongue of bone lies on the inferior aspect of the neck, or, as in the second case, it represents the tongue of bone which lies *on* the *posterior* aspect of the neck of the femur. Now, I have cut across such a specimen as this in two cases: one where there was a posterior tongue, and the second where there was an inferior tongue. The first specimen is from a subject in the dissecting room at Guy's Hospital; the second specimen was given to me by Dr. O. W. Greene of Gloucester. And in both cases it will be found that these tongues of bone are due to a deflection of the line of fracture along these lamellæ, either vertically or horizontally. Now, it is hardly conceivable, on external anatomical grounds, to suppose that a fracture started from below or from behind. But this starting place is rendered more doubtful by the fact that had it started in this *position*, that is to *say*, either *behind* or below the neck of the femur, surely it would *have continued to* pass along those lines of pressure lamellæ and involve the head which it rarely does. As a matter of fact, for two-thirds of the total thickness *of the fracture the line of fracture has* been transverse to the long axis of the neck. We may therefore reasonably assume that these specimens point to the fracture having begun either above or in front of the neck of the femur, and the line of fracture has then been deflected along the course of the lamellæ or the grain of the bone.

FIG. 5.



Showing transverse section of head in intracapsular fracture showing line of fracture deflected along course of pressure lamellæ.

Now, this specimen of bone, the transverse section of which I have indicated in Fig. 3, shows that quite close to the head of the femur there is a groove (G.A.). This groove, as is indicated by a *transverse section* of a *formalin-hardened* hip, is quite clear, and shows that the structure responsible *for this groove* is the anterior ligament of the hip-joint. Now, although the anterior ligament of the hip-joint *may produce* a groove on the neck of the femur close to the head, two other *conditions* are met with as a result *of the pressure* of the anterior ligament upon the inner part of the neck of the femur. These two *conditions* are: *first*, a prolongation of the articular surface of the head on to the front surface of the neck of the femur; and secondly, a distinct raised impression separated by a distinct and narrow groove from the head of the femur. This may be apparently covered by cartilage in a recent state. Now, if this ligament produces any one of these three conditions which I have described, either the groove or the prolongation *of the articular* surface of the head, or the raised impression, it is clear that it must exercise some pressure upon the part against which it lies. And when we consider that it is put on the stretch every time we stand in the erect position this pressure will be easily explained. Now, when *a patient* gives a history of the accident, which in his case is associated with intracapsular fracture of the neck of the femur, two points are brought out: either that he tripped up *over* a *carpet* or some such object and fell (frequently it is said that he tripped up over the other *foot*), or he may give the history, as he frequently does, of having apparently *recovered himself* and then felt that something had gone in the region of the hip. What has *happened* in the first place is that, owing to the extreme flexion which has been produced and to the internal rotation, and possibly also to the adduction of the femur, the anterior part of the surface of the neck has come into contact with the anterior and upper lip of the acetabulum.

From this standpoint it will be seen that the orographical and climatic features, and particularly the presence or absence of dangerous parasitic diseases, whether of animals or man, have had a great influence in shaping the main outlines of the history of Africa.

Africa is naturally divided into several zones. 1. A littoral strip along the Mediterranean, with a rainfall in winter and spring, with conditions somewhat resembling those of Southern Europe, modified by the proximity of the desert. This region from the earliest times has been the home of the Mediterranean race. 2. A desert zone. The Sahara in the north, a large part of which is absolutely waterless desert and the rest poor scrub-land, with vegetation limited to small plants arranged to avoid evaporation from the surface of their leaves—e.g., the gum acacia and tamarisks. These conditions are reproduced on a smaller scale along the coast from Loanda to the Cape and in the Kalahari desert. Both these areas have served as barriers to progress, though great trade routes are found along the chain of oases across the Sahara. 3. A great pastoral zone on the northern plateau in the Central Soudan, on which great herds of cattle and horses can be reared, and in which agriculture is practised to a greater or less extent. 4. Western Equatorial Africa, an area of great heat and humidity, occupied by dense forest. This area is, on the whole, unfavourable to animal life. 5. Eastern Equatorial Africa consists largely of elevated open forest and savannah, the home of great game, and affords good pasturage, where the various parasitic animal diseases permit, and is suitable for agriculture. The rainfall, however, diminishes, so that the pasture is somewhat less certain towards the south. The southern region is well adapted to agriculture when irrigation can be extensively practised, as has been done from mediæval times, e.g., in Rhodesia. The coastal strip on the south-west is desert; on the south-east it is very humid and hot and consists of marshes and forest.

The hygienic conditions of large parts of these areas may be summarised by saying that Equatorial Africa is the home of great groups of diseases due to animal parasites. In all the coastal marshes and all the areas of marsh and shallow lake arising from the expansion of the inland rivers, malaria is rife and almost all the parasites of men the alternative hosts of which live in or around shallow waters are to be found. Malarial disease no doubt affected the progress of man across the continent and led him as far as possible to keep to the healthier uplands—the avoidance of the Nile-Sobat valley by the Abyssinians being a case in point. Animal diseases have had an equal effect, more particularly the diseases due to trypanosomes and conveyed by flies of the genus glossina. Nagana or tsetse-fly disease is found along the eastern coastal zone from Zululand northwards to German East Africa. It extends up the Limpopo valley into the Northern Transvaal, affects the Lower Zambesi and Shire valley, extends along the eastern shores of Nyasa, into the basin of the Luapula, is common all round Lake Tanganyika, has been found at several points in the basin of the Congo, and thence northwards to the Camerun and the Benue, and up the Niger in the low-lying ground above Lokoja, though cattle can be kept in the dry season when the fly is scarce but must be driven away from the river in the wet season. Tsetse flies and nagana have been found along the banks of the Shari but are absent from the shores of Lake Chad. An allied disease spreads through Togo-land into Southern Guinea. The upper waters of the Kassai and Zambesi present the tsetse fly but no nagana. The areas thus marked out are avoided as far as possible by pastoral tribes and have presented formidable barriers to migration.

The outside influences of negro Africa have all come from the north and east. The one great line of communication from north to south—the Nile valley—was largely closed by the great marshes or hidden lakes choked up by great masses of floating vegetation, the sudd, from Fashoda to Lado. These checked the direct influence of the northern peoples from the Nile valley in the Great Lakes and diverted them westwards into the Central Soudan. The route from the Abyssinian Highlands past Lake Rudolf, however, remained open and seems to have been from very early times a line of racial pressure.

[Dr. Shrubsall proceeded to give an account of the domestic animals of the African tribes—the dog, the goat, cattle, and fowls. He continued:—]

The history of the negro tribes is to be derived from references made by travellers visiting their districts, supplemented by some evidence from linguistic and native tradition. Archæology affords little help over the greater part of the area as native building seem to have almost always been of a perishable nature. There are earlier records of the history of the Soudan than of any other part of negro Africa. The very earliest refer to the district between the Senegal and the Upper Niger, known in mediæval times as Ghana. It is said that white kings ruled over this district before the year of the Hegira (622 A.D.). The Arabs visiting this country in the eighth century found it ruled by a black monarch to whom the Berbers of the desert towns paid tribute. The Wolof who then inhabited it are described in the Tarikh es Sudan as the best of men. Between 900 and 1050 the supremacy of the black kingdom of Ghana was acknowledged by the towns on the Saharan border and oases inhabited by whites. The town of Ghana is described by El Bekri as "the resort of the learned, the rich, and the pious of all nations." The town at that time was divided into Mahomedan and pagan quarters. Magic and trial by ordeal were in use. Ten days to the south of Ghana was the country of the Lem-Lems, or cannibals on whom slave raids were constantly being made. By the middle of the eleventh century we learn from El Edrisi that the king and his chiefs of Ghana were Mahomedans. Of the country between the Niger and Lake Chad El Berri gives information that there was a great kingdom, extending for eight days' march, of which the kings bore the title Der; and beyond this came Kanem, a country of the idolaters. The first kingdom was doubtless Bornu.

By the fourteenth century the Berbers had pressed south and had formed a series of peoples at the southern edge of the desert from the Atlantic to the Nile but subject to the black kings of the Soudan. In the thirteenth century arose a great black kingdom of Melle in the Western Soudan, extending from the Atlantic to the Niger and northwards into the desert. The kings of this State accepted Mahomedanism and made pilgrimages to Mecca. This kingdom was visited by the distinguished traveller, Ibn Batuta, from whom we have a description. The rulers of this kingdom were received on equal terms by the rulers of the Northern Arab-Berber civilised States. Beyond Melle the Niger was said to enter a region of swamps and cannibals.

The Mellestine Empire was succeeded by the Songhay, which stretched from the Atlantic to Lake Chad and northwards across the more habitable parts of the desert almost to the borders of Egypt. This empire maintained a high state of civilisation and culture, and libraries were highly valued therein. In the sixteenth century this part of the Soudan was subdued by the Moorish kingdom, and although the military governors of the district became independent, the Soudan disappears from the knowledge of the Western European peoples. Between the peoples of this part of the Soudan, who from the earliest period of which we have records seem to have been of mixed blood, and the purer blooded negro to the south a gulf had always been fixed. In Haussa country several more or less powerful States had existed throughout this time the history of which is more or less known. They remained pagan longer than the more northern districts. The neighbouring State of Bornu also has an illustrious history and, if this is to be believed, adopted firearms long before Eastern Europe. The possession of these enabled this State to resist the Moors who had overthrown their neighbours of Songhay. The Hausa States were overthrown by the Fulah in the beginning of the nineteenth century and are said then to have been pagan.

The evidence of history, from Herodotus on, seems to show a gradual pressure of the negroid peoples driving the unmixed negro to the limits of the district inhabitable by the intermixing race.

The Fulah are a negroid rather than a negro people, very difficult at present to classify. Sir Frederick Lugard describes them as closely resembling the Bahima of Uganda. Although in history they are found to the west, and their invading march in the nineteenth century was from west to east, their traditions are that they came from the east, though most authorities regard it as more probable that they owe their origin to an incursion of Berber or Mediterranean peoples, the Northern Hamites, into the Senegal from across the Sahara.

The Eastern Soudan has so far as its history is known been the scene of raids from the Hamitic-Semitic tribes who occupied zeribas much as the Fulahs did walled towns in Hausaland, the people whom they ruled being liable at any time to be seized as slaves. None the less, many of the raiders were of native race. Protected by the marshes of

show it to you, or this specimen, it will be clear that the portion of bone which is separated by the primary fracture at the base of the neck is a most dangerous weapon, and it is upon this chisel and its shape that the secondary fractures, the position of which is remarkably constant, depend. Now if we examine this chisel by sections made through the long axis of the head and neck bone fibres will be seen radiating from the narrow part into the broad part of the neck, as is indicated in this diagram (Fig 8). If, however, a section be made parallel with the former but lower down the neck, the apex of the wedge—that is, the cutting edge of the blade—is formed by the calcar femorale (Fig. 9). According to Hamilton and Gant, and as shown in some of the specimens illustrating these lectures (Fig. 10), there are in addition to the primary fracture, which we have seen separates the chisel portion of bone from the shaft and trochanteric region of the femur, two other lines of fracture commonly present which pass through the great trochanter and upper part of the shaft of the femur. These fractures may be called secondary. They may be distinguished as vertical and horizontal, although this is not quite an accurate conception of their direction The first or vertical line of fracture runs from the front part of the summit of the great trochanter downwards and backwards through the outer surface of the great trochanter and shaft of the femur to the lower part of the spiral line below the small trochanter, and then turns upwards and forwards to join the primary fracture at the lower and outer part of the neck of the femur. The second, or horizontal line of fracture, passes from the posterior intertrochanteric line just below the digital fossa outwards and forwards, either slightly downwards or slightly upwards, through the base of the great trochanter, to meet the vertical line of fracture.

The causes producing these lines of fracture, including the primary line as well as the secondary lines, may now be considered. In the primary line the line of fracture behind occurs under shelter of the *posterior* intertrochanteric line, where the compact bone is exceedingly thin and where the *compact* lamina forming the inner surface of the posterior intertrochanteric line or wedge *passes* into the compact lower lamina forming the posterior surface of the neck. *These two laminæ* run into each other at practically an angle of 90°. These two anatomical *conditions* are potent causes in determining the position of the posterior line of fracture, and *mutatis mutandis* the upper limit of the fracture may be explained in the same way. The anterior line of fracture occurs just where the thick compact lamina on the front of the great trochanter passes suddenly into the thinner compact lamina on to the anterior surface of the neck. Numerous vascular foramina may be observed lying along this line and these tend to weaken the bone in this situation. The apex of the wedge and the shape of the chisel blade of the neck is formed, at any rate in the lower half of the neck, by the calcar femorale. Moreover, the lower limits of the fracture correspond to the lowest level of the calcar femorale, as shown in this specimen of unimpacted extracapsular fracture of the neck of the femur (*vide* also Fig. 7). This specimen also shows the calcar femorale lying exactly opposite the secondary *vertical line of fracture*, but this relation is seen more clearly in this specimen of an extracapsular fracture of the neck of the femur. The vertical line of fracture may, then, be considered to be due to the calcar being driven against the *great trochanter* and upper part of the shaft of the femur. The horizontal secondary fracture may be, perhaps, due to the rotation of the shaft of the femur backwards, which is practically always a prominent sign of fracture of the neck of the femur. This rotation of the shaft causes the posterior intertrochanteric ridge to impinge forcibly against the posterior surface of the neck, exactly where the calcar rises from the posterior compact lamina of the neck, as shown in this specimen, and so a horizontal line of fracture is produced. From the illustrations of actual specimens it may be concluded that the calcar femorale plays an important part in the production of the shaft of the blade of the chisel portion of the head and neck, separated from the rest of the bone, in that it not only supports the cutting edge of the blade but also its pointed lower limit. When this chisel is driven into the great trochanter and upper part of the shaft of the femur, its blade, formed and supported by the calcar, is certainly responsible for the vertical splitting of the shaft. Strengthening of the posterior compact lamina of the neck by the calcar may also be held responsible for the horizontal fracture.

A few remarks may now be made with regard to the anatomy of the calcar femorale. I said at the beginning of my lecture that it might be studied in an incomplete manner by cutting transverse sections of the upper end of the femur, that it might be better examined by cutting obliquely transverse sections parallel with the long axis of the head and neck of the femur. But it may be still better examined by a somewhat tedious dissection, in which the outer surface of the upper portion of the great trochanter is trephined and the loose cancellous tissue picked away with some sharp steel instrument so that the calcar femorale remains intact. This is the plan which was recommended by Bigelow. In such a specimen the calcar is seen as a nearly vertical ledge of compact bone, having an anterior surface, a posterior surface, an internal attached base, and an outer edge. This ledge of bone passes downwards and slightly forwards, beginning above in the compact tissue of the posterior sloping

OBSERVATIONS ON BLOOD PRESSURE, CHLORINE RETENTION AND DECHLORINATION, HYPERACIDITY, AND VARIATIONS IN THE STARCH RATION.

BY HUBERT HIGGINS, M.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

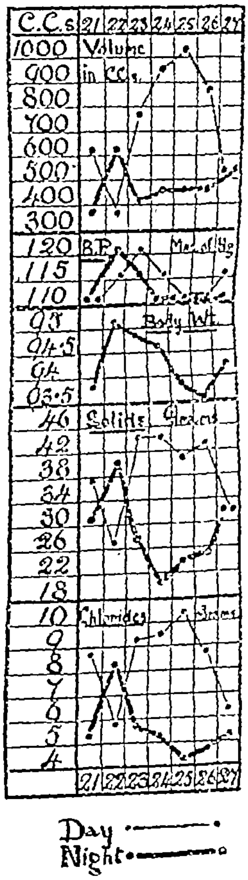
LATE DEMONSTRATOR OF ANATOMY TO THE UNIVERSITY OF CAMBRIDGE AND ASSISTANT SURGEON TO THE ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THE following observations have been made during the past five years mainly with the object of ascertaining the factors producing variations in the starch ration, or, in other words, the influences determining the quantity and quality of the starch metabolised by the body. It was found necessary to make observations twice a day so as to differentiate between variations due to work and rest. The importance of the faculty of using starch as fuel in the case of protoplasm in general is thus stated by Loeb: "We know that the peculiar phenomena of oxidation in living matter are determined by fermentative processes, and we venture to say that fermentations form the basis of life phenomena. It has been demonstrated that fermentation is a function of the geometrical configuration of the molecule. ...... The influence of the geometrical configuration goes further. Voit has suggested, and Cremer has demonstrated, that there is a far-reaching parallelism between fermentability and the assimilation of carbohydrates."[1]

The conditions that have been somewhat unexpectedly under observation have been hyperchlorhydria with as low a starch ration as 50 grammes; hyperacidity; hypoacidity; chlorine retention, with both forced and spontaneous dechlorination; the substitution of a normal blood pressure of 100 millimetres of mercury for one of hypertension of probably 20 years' standing after passing through a phase of hypotension, purpura, and rheumatism associated with calcium and probably magnesium "stasis."

It would appear to be probable that these conditions are fundamentally due to an alteration of the molecular constitution of the protoplasm that has the effect of disturbing the balance between the aerobic and anaerobic functions of the cells. This conception of animal protoplasm is that of Gautier found in his essay on "La Chimie de la Cellule Vivante," where he sustains the thesis "that the animal cell, far from living entirely an aerobic life, has within the protoplasmic substance anaerobic functions." Further, he maintains that the aerobic processes are required in order to oxidise and render harmless the products of the primitive anaerobic changes. The main anti-aerobic influences to which human protoplasm is exposed are the following. 1. Cold. The protective vaso-constriction found in response to the stimulus of cold not only prevents the loss of heat but must necessarily interfere with the nutrition of the skin and its supply of oxygen. It is suggested that it is in consequence of this interference with the vitality of the cuticular protoplasm that there results the formation of toxic katabolites which affect the general mass of protoplasm in proportion to the area of skin exposed to the cold. 2. Mental and physical fatigue. 3. The introduction of anaerobic toxins from the growth of micro-organisms within the body or from the intestinal canal. The typical reaction is illustrated in Fig. 1 in its simplest terms. It was caused by an unaccustomed mountain climb on the 22nd. A hearty meal was taken at midday but no food afterwards as there was an absence of appetite. A good description of this general reaction to fatigue is found in a paper by Dr. Mahomed describing the condition of Weston the famous pedestrian.[2] "He became sleepy, his pulse tension was now considerably increased, there was a coincident fall of temperature. His hands felt cold instead of glowing as heretofore, he complained of feeling chilly and required more bedclothes. The second sound of his heart was accentuated and the first a little prolonged (March 10th and 11th). On March 12th his temperature went up, his pulse tension became low, and his extremities warm. After this he was able to walk easily and well till the end of the match." The reaction consists essentially: (1) in the retention of water shown by coincident variations of the urinary volume and the body weight; (2) in the retention of solids (Zuntz, Krumacher, Argutinski, and others[3] have shown that there is what is called "retention of urea" till the day following fatigue); (3) in the retention of chlorides; and (4) in the variations in arterial tension. (In this case there was a descending blood pressure.) Some prominent features of variations in hydration, the retention of chlorides and dechlorination, variations in arterial tension, hypoacidity, the metabolic traffic in calcium and magnesium, with some generalities on variations in the starch ration will be successively dealt with.

FIG. 1.



General reaction to fatigue.

Variations in Hydration.

It is well known that variations in hydration play an important part in protoplasmic reactions, increased hydration indicating increased activity. Thus Loeb[4] found that "injured (poisoned) muscle is able to take up water from so concentrated a solution as 2·8 per cent. NaCl, thus exercising an osmotic pressure equal to four or five atmospheres." The increase in osmotic pressure in active muscle, or rather the increase in the amount of water absorbed, has been proved not only by Ranke but also by Miss Cooke.[5] Hirschfeld[6] showed during losses in weight that at first there is a certain degree of dehydration and that the body becomes rehydrated little by little as the weight is regained. This is true of the thin as well as the obese. Dehydration has also been observed in reduction cures in the obese by Dapper, Karchagin, Rodenko, and Javal. Having been in the habit of taking my weight morning and evening for some years I have frequently noted rises in weight from cold, fatigue, and intestinal intoxication. These variations were produced with comparatively small causes when I was in a state of chronic inanition.

fractures is obviously incorrect, yet there is a certain opposition and appositeness about the names which it is convenient to use in indicating two perfectly different fractures. But although the term extracapsular may be useful it is a misnomer, and if a misnomer, therefore, however convenient it may be to the surgeon, it cannot be recognised by the anatomist. I would suggest, with all deference, that the terms of "fractures near the head" and "fractures near the base of the neck" or "near the trochanters" be adopted, and for this purpose I would call in the aid of the Greek rather than the Latin language, and for the term "intracapsular" I would substitute "paracephalic" and for the misnomer of "extracapsular fracture" I would introduce the term "paratrochanteric."

The Hunterian Lectures

ON

THE PYGMY AND NEGRO RACES OF AFRICA.

Delivered before the Royal College of Surgeons of England on March 2nd, 4th, and 6th, 1908,

BY F. C. SHRUBSALL, M.A., M.D. CANTAB.,
M.R.C.P. LOND., M.R.C.S. ENG.,
RESIDENT OFFICER OF THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, LONDON, S.W.

LECTURE III.[1]

Delivered on March 6th.

THE STONE AGE.

MR. PRESIDENT AND GENTLEMEN,—The earliest traces of the presence of man in Africa, as elsewhere, are implements of rough or polished stone. The form of these implements bears a general resemblance to those found in Europe, though an exact classification into series based on form alone is as yet impossible. Many of them are found in the drifts of old river-beds which in the course of time have disappeared and their gravels, resisting denudation, are now often on the tops of hills.

Perhaps the clearest evidence of the antiquity of these gravels, and of the implements which they contain, is afforded by a study of the Batoka Gorge of the Zambesi. This was carefully investigated by Professor Lamplugh and others during the visit of the British Association for the Advancement of Science in 1905. Professor Lamplugh describes the Zambesi above the Falls as flowing in a broad shallow valley in the Central African plateau, being at this point nearly a mile in width. Immediately below the Falls the river is gathered into a narrow gorge about 150 yards wide, with nearly vertical walls of basalt 400 feet in height. This gorge, characterised by numerous abrupt changes in direction, extends for some 60 miles. The broad valley, however, continues as an open outer valley for some distance until it is finally broken up by the series of deep subsidiary gorges cut by each of the tributaries of the main stream.

The fluviatile deposits are scanty and are represented by a few feet of material. On the bottom of this valley the implements are found almost in equal numbers in the outer gorge below the Falls and on the margins of the old valley above the Falls not now covered by the river. The conditions of their occurrence suggest that the river flowed at a higher level than at present when the implements were deposited and that the upper part of the gorge has been since excavated, in which case they must be of considerable antiquity. The workmanship on the implements was always rough, though some specimens showed a secondary chipping, which corresponds more nearly to rough European neolithic work than to the early palæolithic type.

Henry Balfour found on the same plateau above the Falls an implement of a type similar to those of the river drift in Western Europe. It presented a rounded butt for holding in the hand, and the opposite end had been carefully flaked to produce a cutting edge. The same observer revisited the district in the summer of 1907 and found further implements of undoubted palæolithic type in the river gravels.

Implements varying in pattern from rudely chipped stones, usually known as eoliths the artificial character of which is still disputed, to typical palæoliths, recalling Mousterian and Solutrian forms, have been found all over the higher veldt in numerous districts of the Transvaal, Orange River Colony, Natal, and the Cape—some in rock shelters, others in river drift. From some rock shelters pygmy flints and chipped ostrich egg shells have also been obtained.

A similar series of implements has been found in the caves and kitchen middens along the sea coast. The floor of the caves in many cases has been formed into a kind of cement conglomerate from the dripping of water and the calcareous material derived from the shells in which implements and bones are embedded. This conglomerate is usually harder than the sandstone rocks out of which the caves have been hollowed, so that in some instances the floor has been preserved, although the cave itself has disappeared. The commonest implement is of chert quartzite, with a sharp point and two cutting edges. In several cases there were traces of a hearth, around which were split bones, implements, and flakes of quartzite which were probably used as axes and arrow heads. In no case could these flakes be chance chippings from the walls of the caves themselves which were in sandstone. In a few caves skeletons have been found, and on examination they proved to belong to that variety of the Bushman peoples previously described as Strandloopers. It may be noted that no whorl stones, so characteristic of the inland as opposed to the beach-ranging Bushman, have been found in the caves, though common enough on the hill terraces a little farther inland.

In the inland rock shelters similar implements, sets of perforated ostrich egg shell necklets, and rude pottery have been found associated with wall paintings of a type known to have been constructed by the Bushman in historic times. In some of the Knysna caves similar paintings on stone have been found with the remains of undoubted Strandloopers. It is thus clear that the later stone implements were constructed and used by the Bushman. Although there is no direct evidence, owing to the absence of human remains, that the earlier ones were produced by the same race, it can only be said that there is no evidence of any other variety of mankind having occupied South Africa. Stone implements of the river-drift type and others resembling the ruder forms of neolithic Europe have been found over wide areas in Somaliland by Seton Kerr and on the edges of the rift valley by Gregory. In Northern Africa, in the Sahara and the Nile valley, a succession of stone implements is found, the later Nile valley forms being associated with ample human remains.

The osteology of predynastic Egypt has been closely investigated by many observers, and it has been shown that at least two types of man were in existence, the one recalling the Mediterranean peoples and the other resembling the negroes. Arthur Thomson and Randall MacIver distinguish these as non-negroid and negroid types. It is interesting to note that in many features the negroid skulls resemble the Bushmen-Hottentots more closely than the negroes proper.

It seems reasonably established that for a long period of time Southern Africa was occupied by man in the nomadic hunting stage of culture and as there is no evidence of any type other than the Bushman these are generally regarded as the first inhabitants. To the question whence did they come it can only be answered that there is no evidence; no type exactly like them has been found elsewhere. They appear to have certainly occupied the country as far north as Lake Nyasa, and the cropping up here and there of individuals with a Bushman cast of countenance among the Bantu tribes of British Central Africa and German East Africa, as well as among the Andoroto of East African uplands, suggests the probability of a former north-eastern extension. No traits suggesting the Bushmen are now to be met in the Nile valley.

The earliest history shows the Bushman territory being invaded on the west by the pastoral Hottentots and on the east by the agricultural Bantu. The race movements seem always to have been south and westwards, a direction determined largely by the physical features of the country, though it must be remembered that the now desert regions were formerly better watered. The occupation of any site depends both on its suitability for human existence and on its adaptibility to the mode of life of the people thereon, whether pastoral, agricultural, or merely nomadic hunters.

[1] Lectures I. and II. were published in THE LANCET of April 4th (p. 933) and 11th (p. 1050), 1908, respectively.

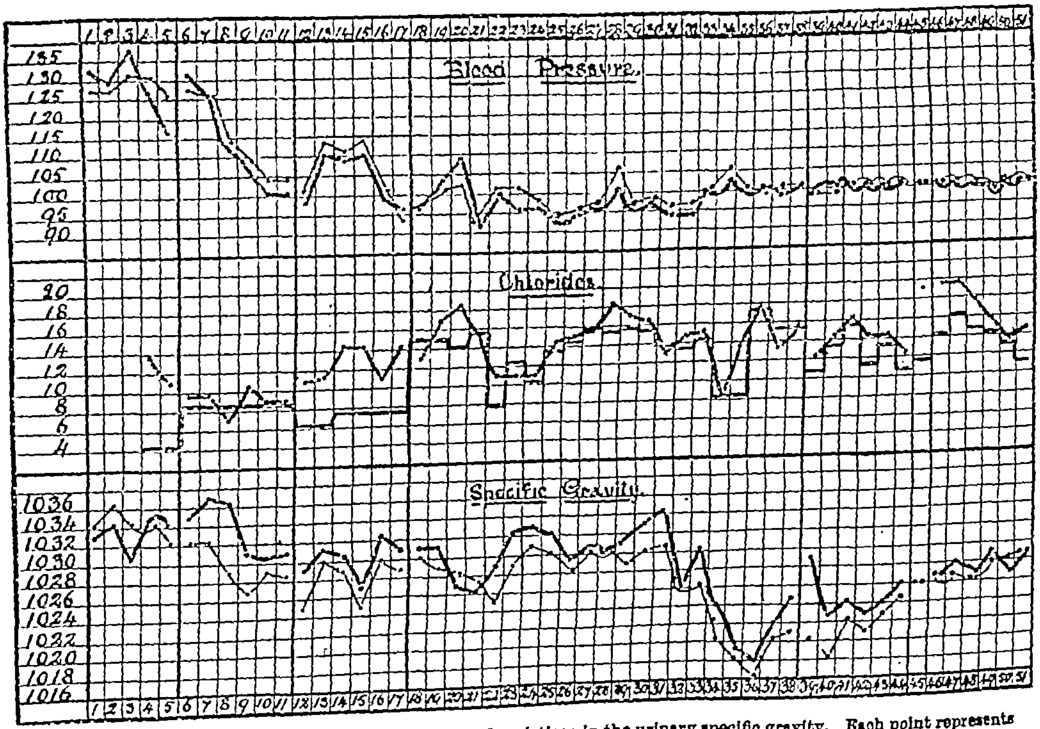
contain from two to three grammes of chlorides. It would appear that the chlorides lost by the bowel are practically negligible; Rohrich and Wik[8] found that, with the exception of the diarrhœa of Bright's disease, the fæcal chlorides never attain to more than 2 per cent. of those ingested. Achard and Ch. Laubry[9] found chlorine retention in at least 50 different acute and chronic diseases. Gaucher[10] found that in skin diseases "there is a high elimination as the case improves, and, on the contrary, the lowest amounts are found at the onset of the eruption, or else in chronic cases where there is a recrudescence of the condition." Marie stated that a healthy individual on a diet containing an excess of chlorides accumulated 92 grammes in 12 days and that 15 litres of fluid were necessary to dissolve it out of the tissues.[11]

The Brussels Analyses, February, 1905.—The average volume was 536 cubic centimetres, the specific gravity was 1031, the average chlorides were 10·09 grammes, the salts ingested were 7·63 grammes per diem, of which 3·42 grammes were found in the fæces; 71·919 grammes of chlorides were eliminated as well as 17·617 grammes of phosphates and sulphates. If it be assumed that the proportion of chlorides to the other salts was the same in the case of the ingesta as well as the egesta 13·58 grammes of chloride of sodium were ingested, constituting a loss of 58·3 grammes. The small salt ration was due to the fact that to facilitate analysis I cooked my own food in the laboratory and had omitted to provide myself with sufficient salt. There was also a daily loss of 4 4 grammes of nitrogen. At this time and for the previous two years I was suffering from the effects of hazardous and ill-considered experiments with a low proteid ration. As will be seen below there is every probability that I had reduced my tissue of phosphorus to dangerously low limits and that there was in consequence considerable retention of chlorine.

1. *From May 15th to June 2nd, 1906.*—There was a forced dechlorination due to a low chlorine ration. It occurred during a period of increased work. During the three weeks subsequent to June 2nd I was exposed to considerable fatigue. Thus on June 2nd, a typical day, the day volume and chlorides were 300 cubic centimetres and 3 grammes and the night 370 cubic centimetres and 5·6 grammes; there was also a rise in weight of 700 grammes, a condition clearly corresponding to that illustrated in Fig. 1. At the end of the three weeks there was a rise in weight of six kilogrammes and a rise in the blood pressure of from 120 to 140 millimetres of mercury. My experiences on this occasion and at Brussels left me with a resolution not to treat cases of parenchymatous retention by artificial dechlorination; I would far rather give copious dilute saline solutions early in the morning as would be done at Homburg with the Elizabethbrunnen.

2. *From July 13th to Sept. 12th, 1906.*—This period was clearly one of either retention or equilibrium. I have assumed that it was equilibrium and that the difference between the ingested and eliminated chlorides represented the daily error of the unestimated chlorides. It is probable that this amount is not sufficient at any rate for 1907, when there was an increased ration.

FIG. 2.



Variations in blood pressure, the balance of chlorides and variations in the urinary specific gravity. Each point represents an average of ten observations.

3. *From Sept. 13th to Nov. 23rd, 1906.*—There was clearly a considerable loss of chlorides; whether it actually reached the total of 350 grammes may be open to doubt, though I am unable to account for any considerable error. The most significant feature of this period was a sudden and decided preference for eggs, meat, and milk. At this time I was not aware of the alleged relationship of phosphorus and chlorine, so the occurrence was decidedly puzzling me. In the course of a day or two, literally, there was a change from having little or no breakfast to having three or four eggs with a large quantity of milk and coffee; eggs, too, had previously caused "biliousness" and were avoided, and throughout the summer, as a rule, there had been an aversion to take even a small ration of meat every day.

4. *From Nov. 24th, 1906, to Feb. 11th, 1907.*—There were fatigue and retention from Dec. 4th to 14th. During the period covered by Nos. 19 and 20 it will be seen that there was an elimination of 57 grammes. Till the end of the summer of 1907 there was a continual ebb and flow of retention and dechlorination, retention always occurring in response to fatigue, cold, &c., and elimination when there was rest. Before dealing with the circumstances that resulted in a further retention and a subsequent dechlorination, I will briefly enumerate some observations made on blood pressure.

the Ghazal Nile and Sobat the negro in this area has remained isolated and unmixed for an indefinite period.

[Dr. Shrubsall proceeded to consider the early history of the people of the Great Lakes district, the Bantu peoples, and the Portuguese colonisation of Africa. He continued :—]

At the end of the eighteenth century Dingiswayo commenced the consolidation by conquest of the coast tribes and Tshaka his general as head of the Zulu tribe built up a great military power which ravaged the whole coastal districts far inland. His attacks caused a section of the Kaffirs, the Amangwane, to invade the territory of the mountain tribes, who in turn advanced in a great horde, known after a woman Mahatatisi, who led them for a time as the Mantati. They spread across the Bechuana territory destroying all before them, sparing nothing that lived along the line of their progress. Defeated by the Griquas near Kuruman they retreated and divided into two groups, one under Moshesh forming the nucleus of the present Basuto people; the other under Sevituane fled to the north into Rhodesia and then to avoid the Matabele still further across the Zambesi to form a military force, known as the Makololo in Barotseland. Later these were exterminated but their language (Sesuto) remains and is now spoken by the Barotse. A few Makololo who were away at the time of the destruction founded a fresh aristocracy over some tribes on the Shire basin where the name but not the language is now to be found. This serves as an example of the value and dangers of language and names as historical guides unless all the facts are known. The present Barotse are no near relatives of the Basuto, yet speak the same tongue; the name Makololo on the Shire means neither similarity in race nor language. Other groups who had been subject to and incorporated in the Zulu armies broke away from time to time under their generals, sometimes to avoid the certain destruction awaiting them if they returned with the object for which they had been sent out unaccomplished. The best known were the Matabele who fled under Moselekatzi in 1820, settled first in the Transvaal, and then, pressed on both by the Boers and the Zulus under Durgaan, advanced north into Mashona territory. Other groups crossed the Zambesi and settled in the Nyasa territory as the Angoni, some of whom even penetrated into Unyamwezi and to the Victoria Nyanza, where they were known as the Watuta. These wars, which lasted over half a century, almost entirely mixed up the tribal organisations in South Africa and may be regarded as typical of events all over negro Africa. The main features in this brief retrospect of the history are a series of incursions from north to south, with occasional brief reflux waves leaving few lasting effects.

From the evidence of the crania we have seen that the type of the Eastern Bantu differs from that of the Western and so far as the few available specimens can show also from the Central. In the eastern group, consisting mainly of the coastal people, the higher type with longer nose and thinner lips constantly crops up and shows a marked similarity in features in all quarters. This would seem to show a certain admixture of a higher type. This type, from the studies in German East Africa, appears to be less frequent around Kilimanjaro and in North Nyasaland than to the south in Kaffraria and to the north in Unyoro. When it occurs it can often be traced to the Zulu reflux wave. If then a group of peoples of higher caste, the product of race mixture of negro and Hamite, had passed down from the Nyanza along the western side of Tanganyika, or at least close to its eastern side, and had crossed the Middle Zambesi, thence trending eastwards, it would agree well with the present distribution. If this type were supposed to be allied to the Hima it might be asked why are the cattle of the Kaffirs not of the long-horned type common in Ankole. It might be that this type bore the journey eastwards less well than the humped cattle, for in travelling to the east coast the invading tribes probably crossed the tsetse zone, and indeed from Dos Santos we know that tribes passing southwards actually did do so. Sir H. H. Johnston has long suggested such a route on linguistic grounds, as shown in the map in his work on British Central Africa. He points out that to some extent the most archaic Bantu tongues existing are still found along this main line of route —Kirega, Kiemba, Cibisa, Isizulu—though a primitive type of Bantu is found here and there to the side of this route, such as the Kimakonde on the east coast near the mouth of the Ruvama river, the Nkonde dialects of the north end of Lake Nyasa, and the Oci-Herrero of German West Africa. The languages of the east coast of Mozambique and German East Africa are in many ways peculiar and have evidently been for some time isolated and have not taken a direct part in modelling the southern speech.

From the western side of the continent we have rather less information, but it would seem that successive streams of Bantu folk from the Congo basin are gradually driving out all non-Bantu elements from even the coastal zone from the Congo to the Sabson.

In the north-east throughout the last century raids have been made by the Masai, a mixed people who have pressed aside the Bantu tribes from much of the higher pasture land between Mount Elgon and Kilimanjaro. The Masai themselves seem to have entered this district from the north and according to native tradition it is only some 50 years since a section of this race was driven from the west of Lake Rudolf by the Suk-Turkana. Farther to the east Galla tribes have from time to time made raids into negro territory and are themselves being raided and gradually displaced by the more warlike Somali, who are gradually extending their dominion down the east coast.

In the Soudan itself the less advanced and less mixed negro has been within recent historic times pushed back at least a degree in latitude into the more unhealthy, humid forest zone. The whole history of Africa is one of replacement of one racial stock by another more richly endowed. The Bushmen were driven to the uttermost ends of the continent to take refuge in mountain fastnesses in which they were safe until the advent of the European and long-range firearms against which their weak bows and arrows were powerless. At the same time the driving away of the great game and its replacement by herds of cattle converted him of necessity from a hunter of the wild animal free to all, to a hunter of those animals which had taken their place, and as these were the property of the usurpers of his country he was termed by them a robber to be exterminated. Even those who had fled into the half desert fastnesses of the Kalahari, as yet not used as grazing grounds, had to suffer a further ill from the advent of pastoral peoples. The cattle plague, which ruined many of the pastoral peoples, also destroyed the majority of the great game, and so has helped by starvation to exterminate the original race of South African man.

The Hottentots, driven back before the white man, make a precarious living in Namaqualand and seem fated to suffer the end they meted out to their predecessors. A few tribes, now all of mixed blood, remain along the Orange River in Griqualand and may by miscegenation attain the right to survive.

The unmixed negro is now nearly everywhere driven into the humid, unhealthy forest zone and river marshes and has been protected therein by acquiring a certain tolerance of some parasitic diseases which take heavy toll of invading higher races. In these fastnesses the negro remains unprogressive, if not retrograde. Now with the aid of hygienic precautions, the drainage of marshes, the opening up of clearings in the forest, the parasites which have been his protection—or perhaps rather the insects transmitting them to man—are being destroyed, and the higher races are able to live longer and longer periods in the old forbidden land. As these changes progress the lower negro tribes unless they respond to the new condition are doomed to disappear and be replaced by mixed peoples. This is doubtless all for the good. We have seen that in early mediæval times a high state of culture existed among the mixed peoples in the Central Soudan and it may be that the results of a similar mixture throughout black Africa will lead to the rise of a more progressive people who will be brought into even closer contact with European civilisation when by steamers and railroads the healthy plateaux are made accessible and become the seats of the newer empire in which each race may play its part.

In conclusion I desire to thank the Council of the College for the honour which they have conferred upon me in appointing me to deliver these lectures.

THE annual general meeting of the University College Hospital Ladies' Association will be held on Wednesday, May 6th, at University College Hospital, Gower-street, London, W.C., at 4.30 P.M. The Duchess of Bedford will occupy the chair.

pressure rose. Digitalis caused dechlorination and a fall in blood pressure.

The observations recorded in Fig. 2 show the association between variations in blood pressure, the specific gravity of the urine, and the retention and elimination of chlorides. 1. The periods from No. 1 to No. 5 are best divided into those before the artificial dechlorination (Nos. 1, 2, and 3), and No. 4 during the dechlorination, when there was a fall in pressure of from 145 to 115 millimetres. 2. From No. 6 to No. 11 from June 2nd to July 13th, when no observations were made, fatigue, &c., caused a rise in pressure to 140 millimetres. The general changes, the prominent objective indication of which was a fall in the blood pressure, were associated with an adaptation to an extremely hot Italian summer. There were considerable weakness and slackness, especially during the first month. A very prominent feature was a remarkably copious secretion from the respiratory passages mainly in the night time; there were also frequent hay fever attacks. During the first fortnight there was a profuse elimination of unpleasant aromatic products by the sweat glands necessitating baths several times a day. There was also a persistent pigmented secretion from the axillæ. At the end of the second week the elimination from the respiratory passages ceased to be prominent and the sweat altered to an odourless, acrid material. By the end of August the sweat became feebly acid. Professor Riva-Rocci tells me that he has seen similar patients who have stayed in bed weeks and even months while the blood pressure was slowly falling. It will be noted that though there was a considerable retention of chlorides there was a low blood pressure during Nos. 9, 10, and 11, and again before the dechlorination in 1907. 3. During periods Nos. 12 to 17 the rise in blood pressure appears to bear some relation to the dechlorination. The rise during Nos. 19 and 20 again appears to be associated with dechlorination. An interesting point will be noticed that during Nos. 1, 2, 3, 19, and 20 the habitual relationship between the day and night readings for blood pressure and urinary specific gravity was altered.

Hypoacidity and Hypotension.

During the second fortnight in April, 1907, at the same time as an English medical man living 20 miles from Varese and a number of inhabitants of the town, I complained of occasional attacks of sensations of intense fatigue with the most decided mental and physical ergophobia. There did not appear to be any rise of temperature recorded in any of the cases. The common feature was a wish to stay in bed or to lie down as much as possible. During May I was less fortunate than my friend, as I was obliged to work and to do some travelling. The consequence was that the sudden attacks of fatigue became more frequent and occasionally alarming. There were both flying and fixed rheumatic pains of a severe sharp "whipping" type that I had hitherto not experienced, though I had been subject to rheumatism for some 20 years. There were also successive crops of petechiæ and large purpuric patches on the trunk and the extremities. I took aspirin regularly without any apparent benefit. The condition became so troublesome that I was obliged to stay in bed. Professor Riva-Rocci was kind enough to see me; he quieted my apprehensions as to the purpura which appears to be of common occurrence in this part of the country.

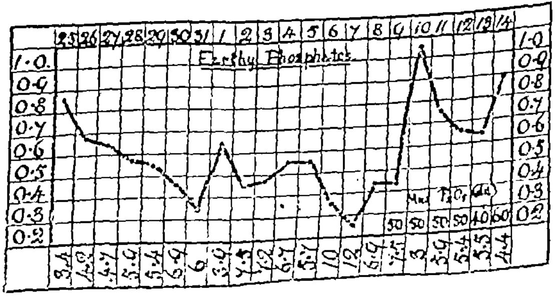
FIG. 6.



Fall in the amount and relative proportion of the earthy phosphates. The proportion of earthy to alkaline phosphates is shown in the lowest line of figures.

It will be seen in Fig. 5 that the prominent feature of the daily analyses of the urine was a change in the urinary acidity, the day acidity being habitually lower than the night. The reality of this state of urinary hypoacidity is shown by the annexed analyses (Table II.) made on six successive days subsequent to exposure to cold and to taking some bad food. It will be seen that the increase in ammonia shows that it is associated with increased acidity. In the beginning of June it was noticeable that the proportion of the earthy phosphates to the alkaline phosphates was falling. (Fig. 6.) At the same time the purpura and the rheumatism were worse. I was fortunate enough to find that by taking from 40 to 60 minims of acid. phosp. dil.

Chlorine Retention and Dechlorination.

Bunge found that "it appears to be the universal rule that those who live entirely on animal food either have never heard of salt, or if they possess it avoid it, whereas the people whose staple food is vegetable have the greatest desire for it or regard it as indispensable." The reason suggested is that potassium has the effect of driving chloride of sodium from the tissues. The theory, however, which is gaining ground is that chlorine retention only occurs when the osmotic equilibrium has been disturbed in consequence of an increased elimination of P_2O_5, or from a deficient ration of phosphorus. These views are held by Maurel, Limbeck, Schwarz, and others. So that Bunge's facts can be explained by stating that where there is an abundance of phosphorus in the dietary *ceteris paribus* chloride of sodium is not required.

In February, 1905, Dr. Slosse of Brussels was kind enough to make a balance of my ingesta and egesta. A loss of 58 grammes of chlorides occurred in a week. Since the spring of 1906 I have made what must be necessarily a rough balance of the chlorides ingested and of those eliminated in the urine. My bread has been specially prepared without salt; no salt was added to my food in the processes of cooking; the salt used was added afterwards from a glass-stoppered bottle filled with carefully dried salt. With this exception my diet has been one that would be recommended by Achard or Widal and Javal[7] as a dechlorinating diet, estimated to

TABLE I.—*Chloride Balance.—Description under Chlorine Retention and Dechlorination.*

this region a man's prestige is determined by his carrying power. My landlord, the "Treeman" as he was called, was over 50 years of age but could easily carry a load of 100 kilogrammes for two or three hours up the Alps. A slight, undersized youth, aged 16 years, carried 48 kilogrammes down the mountain. Men, women, and children over six years of age work from sunrise till sunset; the character of their work can be imagined when it is realised that their hay and corn have to be carried up or down the Alps to the barns. Their principal food is wheaten bread eaten five times a day with milk and they are as poltophagic with their feeding as they are deliberate with their work. Is it possible to continue working in this way till well over 60 years of age without possessing a full faculty for metabolising starch? The devices adopted by those populations who have, practically speaking, nothing but the grim alternative of death when they can no longer metabolise starch are most instructive. The daily hot bath of the Japanese, the Russian, Turkish, and Chinese steam baths have not only the effect of aiding in the elimination of sweat but ensure the skin having an increased blood-supply with consequent metabolic activity subsequently to the bath. The widely spread custom of using vegetables containing potassium such as potatoes, vegetable soups, &c., has the effect of supplying the wastage of this element and preventing the loss of calcium phosphate during cold weather and when there is fatigue. During the silkworm season in Northern Italy, when the peasants work night and day, inquiry has shown that eggs are bought from them with difficulty as they find themselves obliged to add them to their ration. It is worthy of note that the peasant remedy for most ills is to "drink eggs," as they call it, sometimes for long periods. An interesting point is that the factory workers in the new industrial development of Northern Italy, having as yet insufficient wages to enable them to increase their phosphorus and proteid ration, are tending to increase their ration of acid wine, the organic acids of the wine probably acting much in the same way as phosphoric acid. The most prominent cause for the diminished faculty for metabolising starch is clearly the influence of cold. Querton showed that in the case of animals hibernating or when they were exposed to cold the cerebral neurons exhibited the beaded or moniliform reaction of the appendices; this reaction has been produced experimentally by asphyxia, fatigue, electrical stimuli, and such toxins as anæsthetics, morphine, chloral-hydrate, and alcohol, &c. The same reaction has been found in mental diseases. Demoor points out in writing of this reaction: "We know that between the state called pathological and a physiological reaction there is no absolute difference." Hibernation is also found in the case of man when exposed to cold. Thus, in the government of Pskof in Russia when there has been a bad harvest the peasants find themselves obliged to adopt the device of hibernating, or "lozke," as it is called. They are said to wake for a short time at midday, eat a small portion of bread baked in the autumn, and then go to sleep again. To combat the effects of cold the most successful device in the case of both men and animals is to take an abundant meat and fat diet. Its success is shown by almost universal practice and Laulanié and others have found that whereas varnished dogs eat more and live, rabbits, horses, &c., eat less and die in a few days. On the other hand, the power of forming ammonia to neutralise acids can be enormously increased in rabbits by feeding them with amino acids. Ricciardi[22] found that the variations in the degree of toxæmia were dependent on the area varnished. As to the nature and effects of the toxin von Araki[23] found almost constantly albumin, sugar, and lactic acid in the urine which he attributed to incomplete oxidation. In short, meat is required not only for maintaining nitrogenous equilibrium and the provision of suitable fuel but to maintain the intracellular alkalinity, which is probably absolutely necessary in most cases where the individual is exposed to cold or fatigue, or is the subject of chronic disease.

The hibernating animal when first exposed to the cold of the autumn suffers from a low degree of toxæmia which causes an increased appetite and a deposit of fat. Is it due to a similar process that obesity is caused by continuous fatigue and other forms of chronic toxæmia? When the cold, and consequently the toxæmia, increases the intracellular acidity results in sleep, the metabolism is reduced to a minimum, it can be said to be paralysed; it remains in this condition either till the cause is removed or death results. It is irresistible not to find strong resemblances between this condition and that of the varying degrees of temporary or permanent retarded nutrition.

This paper is a record of work that has necessarily been preliminary in its scope. It was undertaken to show how large a field for profitable research there is in the continuous observation of the reactions of the body to the commonplace environment of ordinary life.

Addenda.

Analyses.—The processes employed were: For chlorides, Mohr's method; for phosphates, uranium nitrate; for ammonia, Folin's method; for uric acid, Hopkins's method; for urea, Brandeis's improved hypobromite method was used with his new ureameter. Two solutions, one of ammonium sulphate with one centigramme to two cubic centimetres and another of ammonium chloride with a centigramme to five cubic centimetres, were titrated on each occasion so as to obviate the necessity of making the calculations for barometric pressure and temperature. The earthy phosphates were precipitated by the addition of ammonia and the phosphates were separately estimated. The calcium and magnesium phosphate were estimated by dissolving the precipitate with ammonia in acetic acid, adding ammonium chloride solution and ammonium oxalate, setting aside for 24 hours, filtering, adding ammonia, and making a separate estimation of the magnesium phosphate after putting it aside for 24 hours. The calcium phosphate precipitate and the calcium precipitated from the filtrate after adding ammonia were separately estimated volumetrically after dissolving in hydrochloric acid with a decinormal solution of permanganate of potassium in the way recommended by Blarez.

Varese, Italy.

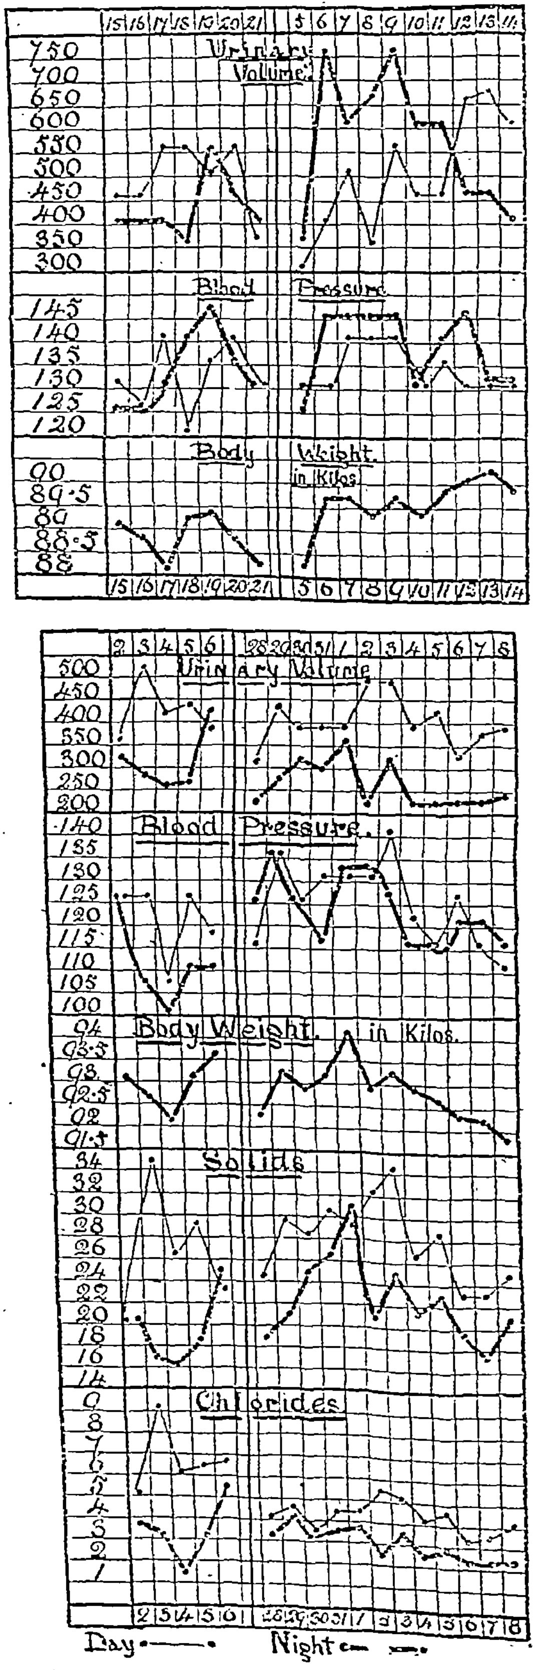

FIGS. 3 AND 4.—Showing the coincident variations of the urinary volume, solids and chlorides with those of blood pressure.

Variations in Arterial Tension.

With the exception of intervals recorded above I have taken my blood pressure by means of the Riva-Rocci apparatus with a large band twice a day since April, 1905. The times chosen were about a quarter of an hour after going to bed and just before rising. In this way it was possible to have the advantage of differentiating between the effects of work and rest, and in addition the observations were capable of being compared over long periods of time. During this time I had the opportunity of observing the change from chronic hypertension to hypotension and subsequently to a normal blood pressure of 100 millimetres of mercury.

The facts observed are most easily explained by the hypothesis that the main factor in the production of variations in arterial tension is changes in the state of matter of the general mass of protoplasm. There is a considerable literature dealing with evidence of general protoplasmic changes. Thus, Dr. A. Haig in his book on uric acid has quoted a number of authors who have described variations in what he calls the "morning" and "evening" state. For instance, Richet, G. Oliver, Marey, Lloyd Jones, Roberts, and others have described well-defined variations in temperature, blood pressure, venous and capillary circulation, the urine, the respiratory interchange and in the specific gravity, the corpuscles, and the hæmoglobin content of the blood. The prominent features of these states can be said to be the common characteristics of certain groups of disease. For instance, in the case of Bouchard's illuminating generalisation in which he distinguishes between the state characterised by active tuberculosis as being associated with free hypotensive circulation, hyperazoturia, and demineralisation. After rest and superalimentation this same case will present the signs of hypertension, chlorine retention, &c.; in short, all the symptoms of retarded nutrition. The prominent features of this retarded nutrition characterise most of the chronic diseases such as obesity, arterio-sclerosis, renal disease, &c. Are these conditions associated with persistent protoplasmic superhydration in the case of retarded nutrition and in that of accelerated nutrition with a state of matter where there is either inherent inability of the protoplasm to react by increased activity and superhydration either from want of vitality or from excessive toxæmia?

The observations recorded in Figs. 3 and 4 were made while there was a descending blood pressure. It will be seen that in these circumstances there are clear indications of associated variations in the blood pressure, body weight, urinary volume, solids, and chlorides. Very little attention has been paid to the forces exerted by the protoplasm itself through the lymph on the capillaries and the blood pressure generally. Yet the extent and forcefulness of the protoplasmic reactions are thus stated by Loeb: "The theory of osmotic pressure indicates that the osmotic pressure in the cells is 20 times as high as the blood pressure."[12] Also that injured muscle is able to take up water from so concentrated a solution as 2·8 per cent. of chloride of sodium, a fact that is of importance in the explanation of œdema.[13] Again, he states that: "Injuries (poisons) lead according to their nature to a swelling of the cells or to a secretion of fluid into the body cavities."[14] Another important observation is that of Hess who was working with healthy animals and found that when the blood pressure was artificially varied the arterial pressure steadily maintained its composition; the venous pressure, on the other hand, became more concentrated when the pressure rose, more diluted (as much as 25 per cent.) when it fell.[15] If toxins are capable of producing such powerful reactions as those described it is only reasonable to suppose that provided the reaction be sufficiently extensive in its operation the state of matter must necessarily exert considerable, if not a preponderating, influence on such general conditions as hyper- or hypo-tension.

Ambard and Beaujard[16] pointed out that hypertension is intimately associated with chlorine retention. Thus, in Bright's disease they were able to provoke variations in blood pressure with dechlorination. In one case a dechlorination of 46 grammes caused a fall in the blood pressure of from 220 millimetres to 130 and when 38 grammes were retained the pressure rose to 160 millimetres. Also in tuberculosis they found that when chlorides were retained the many instances expert bacteriological examination fails to isolate the Klebs-Löffler bacillus in cases of unmistakeable diphtheria and, on the other hand, there stands the indubitable fact that the bacillus is often to be found in the noses and throats of apparently absolutely healthy subjects. Cases not associated with the Klebs-Löffler bacillus are looked upon by many as anatomically similar but bacteriologically distinct diseases and are termed "diphtheroid affections" or "pseudo-diphtheria." Some of these cases are ascribed to organisms belonging to a different biological group. Thus authors describe a "streptococcus diphtheritis" caused by *Streptococcus pyogenes*. Others are produced by bacilli morphologically similar to *Bacillus diphtheriæ*, but differing from it either in cultural peculiarities or in pathogenic properties. The latter are called pseudo-diphtheria bacilli. With regard to the diphtheritic affections of animals information is very scanty. I will summarise it briefly under separate headings.

The horse.—Diphtheritis is known to occur in the horse. It is a fatal and contagious disease, called croup or angina by veterinary surgeons. Dr. Turner[4] mentions one or two cases of diphtheria in man preceded or followed by a similar disease in the horse. Professor W. J. R. Simpson, who made inquiry for the Local Government Board as to a prevalence of diphtheria in and about Shaftesbury in 1885, says that according to the testimony of a veterinary surgeon in the locality a so-called "laryngitis with sore-throat" had been by no means uncommon during the epidemic. Dr. Louis Cobbett[5] refers to a case in the horse in which the Klebs-Löffler bacillus was isolated from the nasal discharge. The animal belonged to the father of a girl who was suffering from diphtheria. Stevenson[6] points out how frequently the disease attacks children living in mews and occupying rooms over the stables. Dogs and cats frequenting the mews also suffer in the same way. The far greater prevalance of diphtheria among mounted troops than in infantry is no doubt connected with disease in the horse. It has been found by Longuet that in the French army for the period 1872-85 the relative proportion of diphtheria among cavalry and infantry was in the ratio of 10 to 3. In the German army, 1874-82, diphtheria was more than three times as common among cavalry as among infantry.

Cattle.—The disease is known as croup or angina in full-grown animals but in calves it is called diphtheria. Young cattle, varying from a few weeks to a few months old, are especially liable. The disease usually occurs during the fall of the year. Damman, who first described "calf diphtheria" in 1877, believed it to be identical with human diphtheria, but Löffler, who investigated the disease for the German Imperial Board of Health, found a bacillus which forms long undulating threads and differs in many other respects from the *Bacillus diphtheriæ* of man. The relation of cattle diphtheritis to human diphtheria is strongly suggested by the frequent spread of the disease amongst human beings by the agency of milk. Power, in 1878, was the first to show that diphtheria might be disseminated in this way. Since then many outbreaks have been traced with the greatest certainty to milk. The annual reports of the medical officers of the Local Government Board furnish many interesting facts bearing on this question. In the report for the years 1889-90 an epidemic in Macclesfield district is described. It was noticed that almost all the patients had procured their milk from the same dairy and that those members of each household who were the chief drinkers of raw milk were attacked first. On inquiry at the dairy it was ascertained that some days previous to the outbreak the milk of a newly purchased cow, which had recently calved, had been added to the stock of milk. This cow was segregated and the issue of her milk stopped, and from that time no fresh cases of diphtheria occurred. After some weeks the milk of this cow was again sold and soon after fresh cases of diphtheria followed amongst the customers who used it. On the teats and udder of this cow vesicles and pimples were found at the time of the second series of cases. Dr. E. Klein[7] inoculated milch cows subcutaneously with cultures of *Bacillus diphtheriæ*. A swelling appeared at the seat of inoculation and subsided in a few days. On the teats and udders three to four days after inoculation vesicles, pustules, and ulcers appeared. In the lymph from these induced vesicles the diphtheria bacillus was demonstrated both in cover-glass preparations and by cultures. These cows showed a slight febrile reaction during the first two or three days and coughed slightly while the eruption manifested itself. Cultures from the milk showed diphtheria bacilli. Eventually the cows succumbed to the disease, one after 14 days, the other after 24. In 1890 Dr. Klein[8] observed ulcerative eruptions on the udders of cows whose milk was suspected to have conveyed diphtheria. The eruption was similar to that produced by experimental inoculation. It has been objected that the lesions observed by Klein on cows' udders were possibly those of cow-pox and that the milk may have been contaminated by human agency after leaving the udder. Of course, it is quite possible for milk to become contaminated with the *Bacillus diphtheriæ* from the hands, bodies, or clothing of milkers, dairy attendants, and milk handlers, who either have diphtheria themselves or have been intimately associated with diphtheria patients, and Dr. Klein has shown that milk once inoculated with the diphtheria bacillus serves as an excellent culture medium for the organism even at such ordinary temperatures as 18°-20° C. But the more we learn of milk as a vehicle of diphtheria the more probable does it become that the infection is much more frequently derived from the cow herself than from specific contamination by the human subject.

Sheep.—The disease is especially prevalent in young lambs; it is in every way similar to that of calves.

The hog.—Diphtheritis has been described from the hog by several authors. Dr. Sanderson[9] records an instance in which swine in a sty adjoining a cottage in which cases of diphtheria occurred were attacked with the disease as proved by post-mortem examination. In Southern Russia diphtheria is believed to be contracted from swine affected in a similar way.

The rabbit.—Information is very scanty with regard to diphtheritis in the rabbit and other small mammals. I have already mentioned an epidemic of diphtheria in the town of Grafton, Illinois, America, in 1900, which was ascribed to a simultaneously occurring diphtheritic disease amongst wild rabbits.

The mouse.—Dr. Bellard has suggested that diphtheria in man may be related to a similar disease in mice, but on what evidence I do not know. Rats and mice are very refractory to inoculations of *Bacillus diphtheriæ*.

The cat.—The cat is mentioned in numerous reports on outbreaks of diphtheria either as the conveyor of the disease or as having contracted it from human beings. Dr. Klein, writing in 1889, states that cats are subject to an infectious disease occurring in association with human diphtheria, and that "this disease casually occurring in the cat is very similar to the malady artificially producible in that animal by inoculating it with human diphtheria." In 1905[10] the bacteriologist for the burgh of Govan issued a report on the result of his investigations into the possibility of the infection of diphtheria being carried by the lower animals, especially cats. Two cats were examined and from both were obtained and cultivated bacteria corresponding in every respect to those of human diphtheria. In one case the animal had been in the habit of sleeping in the same bed as the patient; in the other the child had been fondling it in her arms. As both cats had been ailing previously to the children becoming affected infection is quite likely to have been conveyed by these animals. Of five cases of diphtheria reported in Govan three patients came from two families living in adjoining properties and two from a house in a tenement directly opposite. In the circumscribed area inclosing the back courts of these buildings there had been a stray cat which had eventually obtained a home in one of the families affected. The animal when examined was found to be suffering from post-diphtheritic paralysis of the legs.

The dog.—The dog may also suffer from diphtheritis. Williams[11] says that during the winter 1878-79 he had the opportunity of seeing several dogs, the property of various owners, that had this fatal form of sore-throat and "presented signs very nearly approaching those of diphtheria as described by physicians."

The pigeon.—Diphtheritis is exceedingly common amongst pigeons, both wild and domestic. The birds are at times literally decimated by the disease which occurs in vast epizootics. Löffler in 1884 isolated a bacillus from the false membranes of affected pigeons. He looked upon it as distinct from that of human diphtheria and proposed to call it *Bacillus diphtheriæ columbarum*. Cultures of this organism inoculated into normal pigeons reproduced the disease with abundant false membranes, they gave rise to milder lesions in fowls, killed sparrows in about three days, produced ulcerations in guinea-pigs, necrosis in rats, and only a slight redness in dogs. The very same year Emmerich stated at the Hygiene Congress at the Hague that he had found in pigeon diphtheritis a bacillus identical with that of human diphtheria. Wheler[12] has observed diphtheria in families that had eaten diphtheritic pigeons.

Fowls and other birds.—Diphtheritis is very common amongst fowls, ducks, guinea-fowls, turkeys, peacocks, pheasants, partridges, parrots, and other birds. The disease in every way resembles that of pigeons, but bacteriologists seem inclined to distinguish, not only in the different orders and families of birds, but in each single host species, various types corresponding to different kinds of bacteria. Without entering into an unprofitable discussion of the many different organisms described, I will point out that several investigators have described organisms indistinguishable from the Klebs-Löffler bacillus—Galler[13] found in the nasal mucous membrane of fowls affected with contagious coryza a bacillus identical in colour reaction and cultural characters with *Bacillus diphtheriæ*. The same or a similar organism was observed by Ferré[14] in diphtheritic lesions in fowls. Guerin,[15] as the result of experiments and observations in many epidemics of fowl diphtheritis, concludes that human diphtheria differs from that of fowls, which he ascribes to a Pasteurella, but adds that twice he isolated from the false membranes of diseased fowls an organism morphologically identical with the *Klebs-Löffler bacillus*. This organism was non-virulent; he therefore believes that it has no relation to diphtheria, but may be the same as the pseudo-diphtheria bacillus so frequently found in the throat of healthy human beings. In 1894 Loir and Ducloux[16] had the opportunity of investigating in Tunisia a diphtheritic epizootic which raged amongst fowls, turkeys, ducks, pigeons, and sparrows. As frequent cases of angina occurred amongst the persons employed on the affected poultry farms the authors made some bacteriological examinations, and in a child suffering from a severe form of diphtheritis they succeeded in isolating the same organism they had found in the birds—a bacillus somewhat resembling the tubercle bacillus. The inoculation of cultures of this bacillus from man reproduced the disease in fowls. In 1896 Ritter[17] found in the false membranes of diphtheritic fowls a bacillus similar to the one isolated by Löffler in calf diphtheria. Chicoli,[18] Boing,[19] Illingworth,[20] Barbier,[21] Bilhaut,[22] and many others have quoted cases of direct transmission of diphtheritis from fowls to man.

Summing up all the available information, it seems to me that our position with regard to diphtheria is very much the same as that concerning tuberculosis. Koch, who discovered the bacillus of tuberculosis in man in 1882, first believed that all forms of the disease both in man and animals were caused

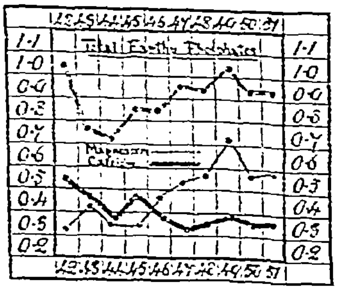
(B.P.) the symptoms were removed in two or three days. I took the acid throughout the summer in from 40 to 120 minims during the day when the symptoms of fatigue or the pains were present. The best guide for the strength and frequency of the doses is to use habitually the same wine-glass or small tumbler for diluting the acid and then to depend entirely on the taste for the strength of the dose. If there is a sharp, unpleasant, metallic acrid taste it is advisable to take less or none; if, on the other hand, it tastes pleasantly acid, as far as my experience goes it can be taken with confidence and impunity. It is stated on apparently good authority that quite large doses—as much, for instance, as 20 cubic centimetres—of the French officinal acid are taken habitually by M. Joulie, whom we are to thank for having originated this treatment. An Italian colleague was able to cause the disappearance of the pain in a case of obstinate rheumatism of some years' standing in a few days; the same result was obtained with another case of some weeks' duration. In a case of bad attacks of trouble-some tumultuous action of the heart with marked irregularity of force and rhythm and true intermission when there had been no sleep till early in the morning the administration of 40 minims of the dilute acid caused the intermission to cease and the pulse to become quite regular (while I was feeling it) in ten minutes at the most. In 15 minutes the patient, who was tired and exhausted, fell asleep.

The influence produced by phosphoric acid on oxidation was shown by C. Lehmann,[17] who noted that after injecting phosphoric acid there was an increase in the respiratory exchange. A probable explanation of its immediate action is found in the fact that "the addition of a slight amount of acid to an $\frac{n}{8}$ NaCl solution shortens the latent period for the beginning of the rhythmical contractions. We shall see later that the acid acts, possibly like the above salts, by liberating calcium from certain organic combinations in the muscle or nerve."[18] Also, "the quotient of the concentration of the Na-ions over the Ca-ions becomes therefore of importance for phenomena of irritability. We shall see that magnesium acts very much like calcium in this respect."[19] It is also worthy of note that acids, especially lactic acid, greatly accelerate autolysis, whereas alkalies, especially ammonia, retard the process.[20] My impression after using phosphoric acid is that it does little to remove the causes but that it undoubtedly exercises a most potent influence in the immediate relief of the sensation of weakness and pain.

FIG. 7.



Showing variations in the proportions of magnesium and calcium phosphate before and after the administration of magnesium oxide. The fall in 51 is due to a lower intake of magnesium oxide.

The Dechlorination in 1907.

No analyses were made for 39 days during October and November. It is practically certain that owing to considerable fatigue, unsuitable food, and exposure to cold the circumstances were those where on previous occasions there had invariably been retention. If the subsequent dechlorination had even been suspected I should have at least have ascertained the chlorides in the night urine. I have therefore estimated that the loss was 197 grammes. There was a repetition of the appetite for eggs, meat, and milk. As it would appear that the mechanism of chlorine retention is closely associated with either a failure to fix phosphorus in the tissues or in consequence of an insufficient diet, it was interesting and suggestive to find that the only persistent feature of my daily analyses was a conspicuous deficiency in the proportion of the earthy to the alkaline phosphates. In addition, there was a deficiency in the amount of magnesium as compared with calcium. On Dec. 10th I commenced taking one or two grammes of calcium carbonate and magnesium oxide. It will be seen in Fig. 7 that it was coincident with an alteration not only in the quantity of earthy phosphates but also in the relative proportions of calcium and magnesium. The normal proportion of earthy to the alkaline phosphates is from 1 to 2 or 2·5, about 0·3 gramme of MgO and from 0·15 to 0·5 gramme of CaO.[21] In my case there appears to be a defect in the metabolic traffic of the urinary magnesium. If this can be remedied and phosphorus caused to be retained it would be an interesting and important fact for application in the treatment of patients in whom there is defective oxidising power. At any rate, up to the present time there does not appear to be any tendency to the ebb and flow of chlorine that was a prominent feature of my metabolism last year subsequently to the dechlorination of 1906. I may add that I have tested my urine on many occasions for albumin but I have not found even a trace once. On one occasion there was a doubtful trace of sugar when there was an unusual amount of ammonia present.

I have found in several cases besides my own that the urinary calcium is roughly divided into two parts, that precipitated by ammonia as calcium phosphate and that found in the filtrate. The filtrate only contains traces of magnesium. I hope to be able to show that the Joulie test for acidity with sucrate of calcium really varies with the calcium that is not precipitated by ammonia, and that it is due to this fact that the variations are found after the administration of phosphoric acid.

Variations in the Day-night Urinary Quotients.

In that most difficult of arts, the daily adjustment of a diseased individual with his environment, it is most useful to have a measurement which shows whether work is carried on beyond the fatigue point. I believe that a useful indication is found by the comparison of the day and night urine. The volume and most of the constituents of the day urine divided by the night is normally from 2 to 2·5. It will be seen that in Fig. 1 it is 1·6 on the 21st and 0·6 on the 22nd. In an extremely serious case of neurasthenia and malnutrition with a blood pressure of 175 millimetres of mercury the night-day quotient was habitually 0·6. In this case there had been sleeplessness for several years. After six weeks' rest in bed, with the exception of an hour daily, the blood pressure fell to 115 millimetres and the day-night quotient was 1·3 to 1·5. This was associated with a considerable improvement in the general condition. The following analyses (Table III.) were from a patient who four months previously nearly died in consequence of a condition that culminated in a fall of blood pressure from 145 to 90 millimetres in a few days. The changes shown in the analyses were the result of rest and an addition of two eggs to the daily ration in the morning. Sleep, appetite, and general fitness were considerably improved. The necessary information can be obtained by collecting separately the 12 hours' urine before and after bedtime when no supper is taken.

Variations in the Starch Ration.

During my work on this subject I have had exceptional opportunities of observing the characteristics of the adaptation of the energetic and resourceful peasantry of certain districts of Austria and Northern Italy. From the standpoint of the science of the conscient adaptation to environment they would afford most valuable material for scientific observation. They have, generally speaking, considerable intelligence and an extraordinary power of forceful and continuous work. The necessarily narrow range of their choice of foodstuffs would make an investigation of their adaptation comparatively simple. As far as my observation goes, the work of a healthy, starch-feeding peasant is steady, untiring, and characteristically deliberate, a point which is well illustrated by the Italian proverb, "Chi va piano, va sano e lontano." I had the opportunity of watching the habits of some Tyrolese peasants near Windisch Matrei while living in a mountain hut for five months during the summers of 1905 and 1906. In single parish, street, or house, and, unlike other contagious diseases, creeps slowly from place to place. Dr. Airy[24] records a very interesting observation. A parish school near the small town of Builth in Wales was attended in nearly equal proportions by children residing in a portion of that town and by others residing in lonely cottages and farmhouses on the hill sides. An outbreak of diphtheria occurred at this school; but the 20 children living in the town escaped, whereas of the 25 living on the hillsides eight were attacked. In all respects except their residence the children appear to have been exposed to the same conditions. A similar instance is reported by Dr. R. Bruce Low from Ashbourne in Derbyshire. A stream divides the town of Ashbourne into two parts. The Ashbourne part to the north of the stream lies mainly on rising ground formed of new red sandstone, whereas the Compton portion is situated on low-lying gravel or alluvium, and is liable to flooding in rainy seasons. The infant school is situated in the Ashbourne division, in a somewhat crowded locality close behind the market place, but the children attending it come from both divisions, the proportion of attendants from the two localities being approximately, Ashbourne 70, Compton 40. "But the diphtheria had been limited to such of the children as resided north of the river in Ashbourne proper."

Although infection from person to person and by means of fomites may be the usual means of diffusion amongst dense communities, we should not forget that diphtheria is pre-eminently a disease of rural districts and that very frequently the disease is scattered over wide areas, the majority of cases occurring in isolated farmhouses without any traceable personal communication. The preference of sporadic diphtheria for high, bleak situations induced Dr. Airy and others to suggest that the specific virus might be conveyed by the wind, and, indeed, it has been noted that the spread of the disease follows the direction of the prevailing winds.

A most striking fact in the epidemiology of diphtheria is its conspicuous invasion of towns within recent years. Taking London as an example, it appears that during the period 1861–70 whilst the diphtheria mortality rate per 1,000,000 living was for England and Wales 187, it was for London only 179. But in the next decennium the rates were 121 and 122 respectively, and in the decennium 1881–90 they were 163 for England and Wales and 259 for London.

Although adults are frequently affected the greatest number of cases occur between the third and twelfth years of life. The greatest number of deaths is between the second and fifth years. Infants in the first half-year of life are rarely attacked. With regard to sex, after the first four years of life, during which there is no difference, the disease appears to be somewhat more frequent in the female. Race is of no importance. Occupation has been disregarded owing to the fact that diphtheria is essentially a disease of childhood. But certain conditions, such as residence on farms or in mews, seem to increase liability to infection. A striking instance is that of the markedly greater prevalence of the disease in mounted troops than in infantry.

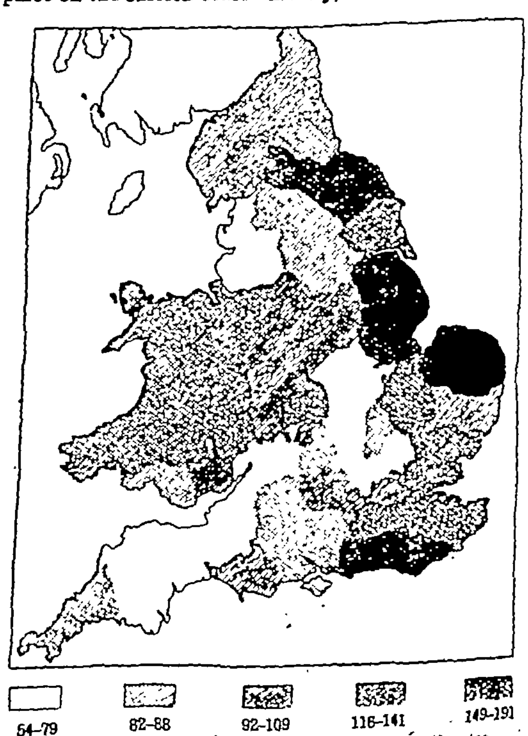
Altitude and geological formation seem to have no influence whatever. The disease has prevailed with equal intensity on high mountains and in deep valleys, along the sea shore and on plains far inland, on dry and wet soil, on basalt, sand, and clay; not infrequently on board ship.

Meteorological conditions seem likewise unimportant; diphtheria rages both in hot and cold weather, during drought and rain. In warm countries it has occurred frequently during the hottest months. In this country, and in temperate countries generally, it prevails far more frequently during the autumn and early winter. It was a common impression among the older writers, and indeed some of the more modern still hold the opinion, that dampness favours the development of diphtheria. The assumption is probably erroneous, but it is certainly a fact that the disease frequently prevails in valleys, along river courses, or in the neighbourhood of lakes and other water bodies. Rainfall seems to have no influence. According to Newsholme, "diphtheria only becomes epidemic in years in which the rainfall is deficient and the epidemics are on the largest scale when three or more years of deficient rainfall immediately follow each other," but many epidemics have occurred with excessive rainfall. Unlike other diseases, epidemics of diphtheria proceed apparently unaffected by changes in the season and weather.

In his monumental work on geographical and historical pathology Hirsch points out that diphtheria epidemics show a distinctly cyclic character. The several cycles have extended over periods of various length, many only a few years, others several decades. The intervals between these cycles have also varied greatly. Not infrequently a period of ten or more years has intervened and the disease on its reappearance was thought to be a new disease. Sometimes the outbreaks have been limited to small districts; in other cases the deadly pestilence has extended over whole countries or even over more than one continent in veritable pandemics. The great epidemics have always been followed by long periods of permanency, especially in the more populous centres, and this has given the disease all the appearances of an endemic.

From these considerations, and from the fact that in many cases the outbreak of the disease in a certain locality can be shown to have been the consequence of its introduction from without, it is only reasonable to infer that, like plague, yellow fever, and cholera, diphtheria must have some permanent area of distribution beyond which it may widely extend from time to time under particular circumstances, to withdraw again to its usual stations after a longer or shorter period of riot outside them. Unfortunately, the only indication we have on this point is one of ancient nomenclature. Aretaeus of Cappadocia (about A.D. 30–90) states that the disease is called Egyptian and Syrian ulceration (ἕλκεα Αἰγύπτια καὶ Συριακά) on account of its greater prevalence in Egypt and Syria.

Of special importance are the distribution of the disease in the various countries and the routes which it has followed in particular invasions. It has been shown by Dr. G. B. Longstaff[25] that during the 26 years 1855–80 the greatest incidence of deaths from diphtheria in this country took place on the eastern coast—namely, in Lincolnshire, Norfolk, East Sussex, and North Yorks; that next in order came East Yorks, extra metropolitan Kent and Essex, counties which are also on the eastern coast, together with Wales and certain counties within or bordering upon the Midlands; whereas the smallest death-rates from this disease were recorded in Lancashire, Devon, and Somerset, on the one hand, and in inland counties such as Bucks, Herts, Northampton, Leicester, and Gloucester on the other.



Dr. Longstaff's map of the average diphtheria death-rates. Twenty-six years 1855–80. (England and Wales taken as 100.)

Having thus sketched very briefly the principal features in the epidemiology of diphtheria, I will endeavour to show

[25] Supplement to the Report of the Local Government Board, 1887.

THE EPIDEMIOLOGY OF DIPHTHERIA

IN THE LIGHT OF A POSSIBLE RELATIONSHIP BETWEEN THE DIPHTHERITIC AFFECTIONS OF MAN AND THOSE OF THE LOWER ANIMALS.

By L. W. SAMBON, M.D. NAPLES, F.Z.S.,
LECTURER TO THE LONDON SCHOOL OF TROPICAL MEDICINE.

IN its issue of Jan. 4th, 1908, the *Field* drew attention to an epizootic of diphtheritis amongst wild pigeons in a wood near London and remarked that "this disease has not yet received the scientific study that it deserves, seeing that it attacks not only the wood pigeon but also domestic pigeons, poultry, and pheasants, and that it is by no means settled whether the avian parasite is the same as that which produces diphtheria in man." The succeeding number contained a letter by Mr. W. Dalziel Mackenzie of Fawley Court, Henley-on-Thames, stating that the disease was raging amongst wild pigeons in the woods of the district and that in one valley 1142 dead birds had been picked up in two days. Further information, published in the *St. James's Gazette* and other lay papers, showed that the epizootic extended for a considerable distance along the Thames valley. Some of the doves picked up dead or dying were sent to me for examination and I was able to ascertain that they had succumbed to "pigeon diphtheria," a membranous disease known to cause severe epizootics among these birds. The same, or a very similar disease, I had seen during the previous months in the domestic pigeon, the pheasant, the partridge, and the sparrow. Through unsolicited information received from intelligent and observant gamekeepers I gathered that some of the diseased pheasants exhibited signs of paralysis, and twice pigeons quite unable to fly were sent to me from the affected districts.

Many other birds are known to be subject to "avian diphtheria." The disease has been observed in turkeys, peacocks, guinea-fowl, domestic fowl, water-fowl, and parrots. Similar membranous affections are known to occur in mammals. They have been described from cattle, horses, sheep, swine, rabbits, dogs, and cats. Indeed, our knowledge of the occurrence of diphtheritic affections amongst animals runs back to the remotest antiquity. Plautus in one of his comedies (*Trinummus*, v. 497) speaks of a deadly epizootic angina amongst swine:—

> *Sues moriuntur angina acerrume.*

Unfortunately, we know next to nothing concerning the etiology of these maladies and their relation to human diphtheria.

That diphtheria may be conveyed from the lower animals to man and reciprocally from man to the lower animals is a very old and general belief. The simultaneous occurrence of diphtheria epidemics in man and of epizootics of a similar nature in animals has been observed again and again in all ages and places. Their relationship is unhesitatingly admitted in the accounts of the great epidemics which desolated Europe between the sixteenth and eighteenth centuries. The deadly epidemic of Naples in 1618 and that of Paris in 1743 are reported to have followed on epizootics of the same nature, and Noah Webster in 1800 mentions the occurrence of fatal angina in man synchronously with a "pestilence amongst cats which swept away those animals by thousands." Amongst recent instances I may mention the epidemic of Frankfort in 1886 and that of Grafton, Illinois, America, in 1900. In Frankfort the authorities became so fully convinced that the epidemic was related to a concurrent avian epizootic, that they issued a warning to the public stating that the disease might be contracted either by direct contact with the diseased birds or by means of milk from cows kept in the proximity of infected poultry. In Grafton the epidemic was preceded by a severe epizootic amongst rabbits. These animals were placed on the market at prices so cheap that they were used largely as food. A microscopic examination showed that they had died from diphtheritis and the physicians warned the townsfolk to abstain from eating the rabbits.

Numberless instances of the transmission of diphtheria to man from fowls, cattle, swine, horses, sheep, and cats have been recorded in medical literature. At the Wiesbaden Medical Congress in 1883 Gerhardt related that a large number of fowls were imported from Verona to the village of Nesselhausen (Baden); some were suffering from diphtheritis when they arrived and about half of them died; all the chickens bred in incubators died, four cats kept in the place died from diphtheria, and four of the six men employed on this poultry farm had diphtheria. One man who was pecked by one of the diseased birds on hand and foot presented false membranes on these parts. No case occurred in the neighbouring village.

Dr. G. Turner, in an interesting report to the Local Government Board, mentions an epidemic of diphtheria that occurred in the village of Braughing in 1883. The first cases were connected with a farm on which the fowls were dying from diphtheritis. Subsequently the disease made its appearance on other farms, where it was also preceded by a similar affection amongst fowls. During the summer of 1886, while investigating epidemic diphtheria at Farnham, he found that there had been simultaneously an epizootic amongst fowls. A similar epizootic had occurred also amongst fowls and turkeys at Ash, amongst fowls at Long Eaton, and amongst fowls and pheasants at Tongham. At Tongham a man bought a chicken from an infected farm and took it home; diphtheria broke out in his house shortly afterwards. This was the first case in the village. Similar disease was noticed amongst the cats at Aldershot, Farnham, Yateley, and Petersfield. At Braughing both swine and horses suffered from sore-throat sickness immediately after the epidemic amongst human beings.

In the *Journal de Santé* of Dec. 23rd, 1888, is an account by Dr. Bild of the first occurrence of diphtheria which, after 30 years of practice, he had seen in the principal town of the small Greek island of Skiatos. It is stated that in June, 1884, Dr. Paulinis was called to see several children who were simultaneously affected with diphtheria, and of whom five died. The epidemic invaded the whole town and in five months 125 persons had been attacked and 36 had died. The cause of this sudden invasion being investigated, it was ascertained that in the locality where the prevalence commenced was a courtyard occupied by turkeys recently brought by boat from Salonica. These turkeys had exhibited false membranes in the fauces, and all had died except one, and in this instance the bird is reported to have been still suffering from paralysis of its feet, which incapacitated it from walking.

In 1892 Debrie[1] reported that soldiers suffering from diphtheria were taken to the Sebdou Hospital. Soon after their arrival certain fowls fed by one of the hospital attendants developed diphtheritis, later the owner of these birds and a soldier who looked after them were also attacked.

Opinion varies greatly as to the value of such records. Whilst numerous investigators emphatically maintain from personal observation that diphtheria may be transmitted from the lower animals to man, others, such as Friedberger and Fröhner,[2] dismiss the whole evidence as "a mere assumption due to utter ignorance of veterinary pathology." To me it seems that the synchronous occurrence of diphtheritic disease in man and in certain of the lower animals observed in almost every outbreak must certainly indicate more than a fortuitous coincidence. Besides, considering that human diphtheria is easily transmitted by inoculation to many kinds of animals it seems only reasonable to surmise that it may be conveyed reciprocally from the lower animals to man. Unless we admit this we must believe in the spontaneous origin of diphtheria to explain its sudden appearance with no history of previous infection or recent importation, an inadmissible theory. Gallez[3] very justly remarks that "if medicine as formerly had remained a science of observation, in presence of the relatively enormous number of facts brought to-day in support of this hypothesis no one would dream of doubting it, and the identity of animal and human diphtheria would be an established fact."

In man diphtheria is now recognised to be due to a specific bacillus, the *Bacillus diphtheriæ* of Klebs and Löffler which in a large percentage of cases may be demonstrated in the false membranes together with other bacteria, some of which, when present and sufficiently numerous, seem capable of enhancing its virulence. Normal cultures of *Bacillus diphtheriæ* inoculated to susceptible animals invariably reproduce the disease, the specific organism may be recovered from the inoculated animals, and the antitoxic serum of immunised animals is successfully employed, not only in the prevention, but also in the treatment, of this fearful disease, the mortality of which it has considerably reduced. But in

[3] Bulletin de la Société Royale de Médecine de Belgique, 1895.

Abyssinia, for instance, the natives look upon the red-throated *Francolin* and other *Phasianidæ* as unclean. The supply of live quails to the English markets is derived from Egypt, Italy, and Algeria. As many as 200,000 are often brought to Leadenhall Market in a month during the season. The quail would explain why the disease was called in ancient times "Egyptian or Syrian ulceration." In Egypt, at the proper season, quails are so plentiful that the people cannot consume, in a fresh state, the number captured and therefore salt them down for future use or dry them in the sun. Diphtheria is even now very prevalent in Egypt, especially in Cairo, although in recent years Alexandria has suffered rather more than Cairo. In Syria the disease is far from rare.

In making post-mortem examinations of birds that had succumbed to diphtheritis I found false membranes in the oviduct of a hen pheasant. This observation brought back to my mind the finding of two small shreds of yellowish membrane some time ago in the albumin of a fowl's egg which I had broken myself, and suggested the possibility of the transmission of diphtheria by means of the eggs of infected fowls. Looking up the literature of avian diphtheritis, I found that several authors have noticed diphtheritic patches in the oviduct of fowls and ducks. Thus some cases are mentioned by Petit in the *Recueil de Médecine Vétérinaire* for April 15th, 1903. Given disease of the oviduct, the *intra-ovum* inclusion of diphtheritic bacteria and even of entire shreds of false membrane is a matter of course. We know that not only bacteria and fungi may be found in the white of birds' eggs but occasionally also comparatively large metazoan parasites. I have myself found on separate occasions a trematode (*Prosthogonimus oratus*) and a nematode (*Heterakis papillosa*) in the eggs of fowls. They had been enveloped in the albumin whilst wandering into the oviduct. If any diphtheritic affection of the fowl is communicable to man, as is very forcibly suggested by numerous observations, then eggs must play an important part in the transmission of the disease.

The conveyance of diphtheria by means of milk and eggs would explain the great frequency of the disease in young children because their food consists almost entirely of these two articles frequently administered to them either in the raw condition or almost raw. It is probably by means of these foodstuffs that the disease is brought into towns, although, of course, it may also be introduced by infected human subjects or by infected animals, especially birds such as the ring dove and the house sparrow. Within recent years the ring dove has become quite common in all the parks and squares of large cities. It may be seen picking the seeds that strew the pavement of cab-ranks. It is quite conceivable that horses and sparrows may contract the disease from these pigeons. It is likewise conceivable that the cat, a natural enemy of the sparrow, may contract the disease from this bird, which is likely to fall an easy prey when paralysed by the disease. The rôle of the cat with regard to diphtheria appears to be of great importance. This animal after prowling in field and gutter has access to the sanctum of the bed-chamber, sleeps on the very bed, is fondled and kissed by the children, especially by the female children. Since 1800, when Noah Webster drew attention to the cat as a factor in the epidemiology of diphtheria, this animal has been noticed to suffer simultaneously with man in almost every outbreak of the disease.

Diphtheria epidemics are made up of extremely severe cases and of very mild ones. The numerous "sore-throats" which precede and accompany an outbreak of the disease may well be compared to the cases of *pestis minor* which precede and accompany the severe and fulminant cases of plague. In both instances the differences in severity may be due to the source from which the infection is contracted. It is quite possible that the parasite direct from some animal may produce in man a milder attack than when it has passed through the human subject and acquired a special adaptive virulence. Sir R. Thorne Thorne explained the relation between genuine diphtheria and the numerous cases of "non-infectious inflammatory sore-throat" noticed prior to, as well as during an epidemic of, diphtheria by "the progressive development of the property of infectiveness," and added, "I know no grounds for refusing to believe that organisms capable of producing a minor and an uncommunicable disease in particular stages of their growth, may in other stages of their growth, or in the course of their subsequent development, become capable of producing a major disease communicable from person to person, the affair being essentially one of soil."

In diphtheria, as in plague, we are confronted by the difficulties of a complex and intricate epidemiology. As in plague, so in diphtheria, a number of different animals seem to play a more or less important part in fostering and spreading the disease. But in diphtheria, as in plague, one particular kind of animal seems more especially concerned in the wider spread of the disease. In plague the rat, owing to its wide distribution, its great numerical prevalence, its close association with man, and, above all, its migratorial habits, is the true cause of the great pandemics which at various intervals desolate the world. In diphtheria probably a similar rôle is played by the pigeon.

It is obvious that in order to formulate efficient measures against any disease it is necessary to have a thorough knowledge of its causation and of the various factors that contribute to its spread and prevalence. I believe sufficient evidence has now been put forward to warrant a very earnest inquiry into the question of the relationship between human diphtheria and the similar membranous affections of the lower animals, and in an inquiry of the kind I should like to see the veterinary surgeon of the modern school take his full share of research work rather than adopt, as in the past, a negative hostile attitude which would be ridiculous in the face of the scanty and crude information at present available on the diphtheritic affections of animals.

Palace Gardens Mansions, W.

A CASE OF CAVITY OF THE LUNG SUCCESSFULLY TREATED WITH OZONE.

BY GEORGE STOKER, C.M.G., M.R.C.P. IREL., M.R.C.S. ENG.

THE conditions that existed in this case make it, as far as I can ascertain, unique, and the results obtained completely confirm facts that I stated long since, facts that were obtained by close work and observation extending over 12 years. For the following particulars I am indebted to Mr. L. Cutler, whom I had the pleasure of assisting in the administration of the oxygen inhalations, &c.

In January, 1907, the patient had pneumonia with pleurisy. For the pneumonia he derived great benefit from the inhalation of oxygen and to a small extent of ozone that was generated in his room. In February he developed empyema and on the 25th and 28th of that month portions of ribs were resected, one in front and one behind. The posterior wound healed satisfactorily but the anterior wound did not; the discharge became offensive with a putrid odour and was dark-bluish in colour and grumous in character. About March 7th he developed blood poisoning. For this latter complication he was treated by Sir A. E. Wright with a vaccine prepared from the staphylococci in the discharge from the wound. He had only two injections, on March 10th and 12th. On the 14th a piece of lung tissue of about the size of a pigeon's egg came through the wound, all the symptoms of blood poisoning disappeared, and from that time he made steady and satisfactory progress to recovery as far as his general health was concerned, but the wound did not show any disposition to close. The separation of the slough and no doubt the suppuration that existed resulted in the formation of a sinus and cavity that together extended to a distance of 6½ inches from the surface of the chest wall to where they communicated with the air passages. Both air and pus passed freely through the external opening. These were the conditions that existed when the patient consulted me in the end of last May Something over two months had elapsed since the cavity had formed. During this period the usual methods of treatment had been tried, including change of air, but as far as closing the sinus or filling up the cavity were concerned without success, though the patient's general health had greatly improved.

I had been able to effect cures in a number of sinus cases and amongst them one resulting from an operation for the cure of hernia which had been in hospital for six years and had resisted all the ordinary methods of treatment. I therefore decided to begin with ozone in the present case for several reasons: (1) Being a much more powerful agent than oxygen it was likely to produce results in less time and thus to shorten the period of treatment; (2) having a strong smell and taste it could be quickly detected in the mouth and nose and so demonstrate its passage through the air tubes; and (3) if eventually, being of the same strength and by the same micro-organism; later, at the Berlin Congress, he declared that he no longer considered the tuberculosis of birds identical with that of mammals; and in 1900, at the London Congress he asserted that bovine and human tuberculosis are quite distinct. Koch's statements embodied not only his personal observations but those of numerous investigators who had shown that tuberculous diseases differ in man, mammals, birds, and reptiles, and that in each class the specific organisms exhibit some differential characters. Already in 1884 Klein had expressed the opinion that human and bovine tuberculosis are not one and the same disease, but against the opinion formed in the laboratory was the opinion formed in the wider field of general experience. The evidence in favour of the transmissibility of bovine tuberculosis to man is overwhelming, and recent experimentation has proved it beyond doubt. I need but mention the conclusions of the Royal Commission appointed to inquire into the relation of human and animal tuberculosis as stated in their second interim report: "There can be no doubt but that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis and that in the majority at least of these cases the bacillus is introduced through cow's milk." Experimental investigation is therefore in perfect accordance with the experience of clinicians (Carmichael, Casper, and Heneke) who so far back as the beginning of the nineteenth century connected the prevalence of scrofula amongst children with the ingestion of milk from diseased cows.

With regard to avian tuberculosis opinion is also very much divided. In a recent paper on the subject[23] Mr. S. G. Shattock, Dr. C. G. Seligmann, Mr. L. S. Dudgeon, and Dr. P. N. Panton maintain the non-identity of the human and avian tubercle bacillus. But their experiments were limited to the infection of pigeons with human tubercle bacilli and of guinea-pigs and one Rhesus monkey with avian tubercle bacilli. The results were positive in both series of experiments, but the human bacillus set up only a local or glandular disease in the pigeon and the avian bacillus proved likewise only slightly pathogenic to the mammal. Had they used parrots and rabbits instead of pigeons and guinea-pigs their results would probably have been far more favourable to the specific identity of human and avian tuberculosis, because both parrots and rabbits are known to be just as susceptible to human as to avian tuberculosis. It is perfectly true that the bacilli of human tuberculosis differ from those of avian tuberculosis in morphological, cultural, and pathogenic characters, but we should not forget that considerable differences are also met with between the tubercle bacilli of different species both of mammals and birds. For instance, the hepatic tubercles of the fowl and of the pheasant are not only distinguishable from the hepatic tubercles of mammals, but they are highly differentiated amongst themselves, although developing in so closely allied animal species. Differences no less notable are observed when tubercle bacilli present in various individuals of the same species are compared with each other. Too much importance should not be given to such arbitrary differences of convenient classification. In very plastic organisms modifications are brought about very easily by environmental changes, even profound structural mutations may occur in a comparatively short time. Schmankewitsch was able to transform the crustacean *Artemia* into an entirely different genus *Branchinecta* within a few generations simply by a change in the salinity of the water. Our domesticated animals and cultivated plants offer numberless examples of extreme variation in members of the same species reared under different conditions. The tiny chihuahua spaniel differs considerably in form, size, and habits from the great Danes or mastiffs of northern Europe. In the numerous varieties of the domesticated pigeon we find considerable changes not only in form, bulk, and plumage, but in the very number, form, and proportion of bones in the skeleton. So great are these alterations that if these creatures were submitted for dissection to a naturalist who knew nothing of the history of the bird he would have no hesitation in classing them as belonging not only to different species but to different genera. Even without any appreciable structural change there may be important biological variations. The stem eel-worm (*Tylenchus devastatrix*) lives and reproduces in various cultivated plants, such as rye, oats, stored onions, hyacinths, buck wheat, potatoes, and clover, and in wild plants, such as *Poa annua*, *Anthoxanthum odoratum*, *Dipsacus silvestris*, and *Polygonum persicaria*, but not to the same extent in all. However, eel-worms, of which the progenitors have developed for many years exclusively in rye or buck wheat, are not easily transferred to another kind of plant or, at any rate, they do not multiply vigorously there. It is the eternal question of seed and soil.

With regard to parasitic organisms that have a wide zoological distribution I think we might aptly compare the several varieties from different kinds of hosts to the various "geographical varieties" of certain free-living species and term them "host varieties." To give them specific value is certainly wrong and misleading. At the utmost they might be classified as sub-species and receive the trenominal nomenclature, as already has been done for the host varieties of certain parasitic mites such as *Sarcoptes scabiei*. The important point is not to forget that all varieties derived from the same species are adaptive forms more or less intermutable. Thus, whatever may be the differences exhibited by tubercle bacilli from hosts belonging to different classes of the animal kingdom agreement is universal as to the identity of their soluble products, notably tuberculin.

With regard to diphtheria and its possible relation to similar membranous affections amongst animals, it is important to notice that of all known bacteria *Bacillus diphtheriæ* is the one which exhibits the greatest variation in morphological characters, cultural peculiarities, and pathogenic properties. The diphtheria toxins, like those of tuberculosis, are the same both in human and animal diphtheritis.

Epidemiology.—It is for bacteriology and experimentation to solve the question of the relation, if any, between human and animal diphtheritis. Meanwhile, however, we should not neglect the study of the epidemiology of the disease because if properly investigated it may not only throw light on this point but disclose other important facts. Unfortunately, the epidemiology of diphtheria has been entirely misunderstood by the majority of investigators and greatly obscured by erroneous etiological preconceptions. Most physicians and medical officers of health even now believe that diphtheria is brought about by faulty sanitary circumstances. It is owing principally to this error that so little progress has been made in our knowledge of the natural history of this formidable disease. A careful examination of reports of numerous outbreaks shows very clearly that insantary conditions of dwellings, defective sewerage, polluted water-supplies, poverty, and uncleanliness have no special connexion with the incidence of diphtheria. It is true that unhygienic conditions may lower resistance and that overcrowding may favour the spread of the disease, but such circumstances are always present in every place. Diphtheria has prevailed with equal frequency and intensity amongst the poor and the rich, in the filthiest tenement houses and in the healthiest surroundings. Dr. Longstaff has shown that in England certain divisions, such as London and the North-Western (comprising Cheshire and Lancashire), which are by far the most densely populated and have the highest general death-rate, enjoy a low diphtheria mortality, whilst others, with a population mainly rural and a general death-rate below the average, show a high diphtheria mortality. Moreover, within recent decades diphtheria has considerably increased especially in large cities notwithstanding the general improvement of sanitation which has so greatly reduced the incidence of other infectious diseases.

Although sanitary conditions seem to have no influence whatever on the incidence and diffusion of the disease, yet many facts point strongly to the existence of some relation between diphtheria and manure.

In the majority of cases infection may be traced to an antecedent case and the influence of school attendance on the diffusion of the disease is now so generally accepted that the closing of schools is the earliest, if not the chief, measure adopted by local authorities to prevent the spread of the disease. No better proof of the contagiousness of diphtheria could be adduced than the fearful holocaust of physicians and nurses that professional devotion has sacrificed to this fell disease. It seems also beyond doubt that infection may be communicated by means of the bedding, clothing, and other articles used by the sick, and that premises occupied by diphtheritic patients may retain the power of infectiousness for months. It is important to notice, however, that the contagiousness of the disease presents certain limitations. It is frequently confined to a placed between the shoulders behind and a pad also over the dislocated head of the bone.

---

[23] Proceedings of the Royal Society of Medicine, vol. i., 1907.

Rose and Carless state that the dislocation is due to violence applied to the front of the acromial end. They advise a figure-of-eight bandage, with a pad in the axilla and one over the sternal end of the bone, and rest in bed.

Duncan Eve, in the Reference Handbook of the Medical Sciences, states that of 497 cases of dislocations particularised at the Hôtel Dieu, Paris, the humerus was dislocated 321 times, the femur 34 times, the clavicle 33 times, the elbow 26, the thumb 17, the wrist 13, and each of the other bones less than 10. Professor Hamilton, in his classical work on dislocations, states that he has seen 57 cases of dislocations of the clavicle, 13 of which were at the sternal end, and 11 of these were forward dislocations of this end, and in not one of the 11 was the treatment successful in preventing an easy recurrence. The sternal end is usually thrown forward by a fall on the shoulder, *front or outside*, by pressure and leverage. Pain and embarrassment in the use of the arm follow. Eve, too, states that it is difficult, if not impossible, to maintain in position after reduction. Stimson, like Hamilton, is equally unfavourable in his prognosis. Wharton and Curtis say that it is unfavourable as to complete correction. Compression over the head of the bone and a figure-of-eight bandage, Récamier's dressing for fracture of the clavicle, Sir Astley Cooper's brace apparatus, plaster-of-Paris apparatus, decubitus for six or eight weeks, have all been advised, tried, and failed. Eve personally favours a carefully applied figure-of-eight bandage, with compression over the head of the bone, to be maintained for six or eight weeks with the elbow secured in proper position by means of a sling and bandage confining the arm to the chest.

Von Bergmann finds this dislocation to be 1·5 per cent. of all dislocations and to be caused by a blow on the shoulder. The deformity, he says, is rarely completely reduced and retention is rarely successful, regardless of the kind of splint or support used. He advises rubber plates over the joint, fastened down by straps, a figure-of-eight bandage, plaster-of-Paris apparatus, injection of alcohol around the joint, König's suturing of the capsule, or Gersuny's transplantation of the tendon of the sterno-cleido mastoid.

Cheyne and Burghard state that this dislocation results from severe violence to the point of the shoulder, backwards in direction, or forwards or downwards. To reduce it the surgeon should put his knee between the patient's shoulders and pull the shoulders back and press the sternal end in; an anæsthetic is generally advisable. It is often a matter of the greatest difficulty to keep it there and a great deal of care is necessary to prevent recurrence. The shoulders should be braced back as for fracture of the clavicle with handkerchiefs and the elbow supported and brought well forward with strapping.

Warren and Gould point out that the joint owes its security to the curves of the clavicle, mobility of the scapula, and play of the acromio-clavicular joint, the sterno-mastoid and pectoralis major tendons adding to the joint ligaments, the costo-clavicular ligament, and the inter-articular fibro-cartilage. Out of 812 dislocations 21 (or 2·58 per cent.) were anterior dislocations of the sternal end of the clavicle according to the St. Thomas's Hospital Reports. Out of 400 dislocations six (or 1·5 per cent.) were of this class according to Krönlein's statistics. It is caused almost invariably by indirect violence to the shoulder, also by muscular action, as in swimming. As to prognosis, though easy of reduction, it can rarely be kept in position and more or less deformity results. They advise a pad in the axilla, plaster-of-Paris apparatus, or the figure-of-eight bandage, and the recumbent position is desirable for at least five or six weeks.

The patient in this case, a girl, aged 18 years, was first seen by me on Dec. 4th, 1905, in consultation with Dr. Danard of Owen Sound. Her trouble was that the sternal ends of both clavicles would so easily dislocate that the performance of ordinary household duties, like pumping water, hanging out clothes, practising music, &c., was impossible. Any movement that threw the shoulders backward and upwards produced the dislocations. She voluntarily dislocated one of the joints in the office for us. When dislocated she was in considerable pain and there was, of course, entire loss of function then of the whole arm. A little manœuvre and pressure and the head of the bone popped in again to its proper place. This had been going on for about five years, a disheartening condition that so reacted on her physically as to produce considerable anæmia and poor appetite and debility.

As to the measures previously employed in her case, her father writes me as follows: "The following remedies were tried but without success: (*a*) the use of shoulder-straps by pressure to keep the clavicles in position, but the effect was to produce dislocation and continue it until the straps were removed. We gave up the use of the straps after a week's trial. (*b*) A local blacksmith under the direction of the family physician made a steel spring fitting into the corset behind, coming over the shoulder and by means of a wooden button and spring pressing on the left clavicular joint. After two weeks this was abandoned. (*c*) A plaster cast was made of her bust and a poroplastic jacket was moulded from the cast with steel springs pressing both joints into position and keeping them there. In a few months ulceration began under the springs. This was somewhat removed by the use of rubber cushions between the springs and the body. She continued to wear the jacket for one year and six months when the family physician decided to discontinue using it. Other remedies proposed but not adopted on proper advice were to fasten the joints with silver wire, to fasten with screws, to pad under the arms and hold the arms back for several months," and I might add, to shorten and suture the anterior ligament of the joint.

When examining this young lady I was struck with the evidence of strength in the joint; it went out with a vicious snap and in again with a quick snap as if strong but overcome with a stronger force. Yet no great effort was being used in producing the dislocation. I concluded it was leverage that was doing it and decided that to spoil the lever would be good treatment. Her clavicles were uncommonly straight, not having that useful but unsightly anterior curve at their inner end. The fulcrum of the lever was evidently the first rib right under the clavicle at the location of the rhomboid ligament, so that when the shoulders went back the sternal end of the clavicle was levered forward. Dr. Danard and I concurred in advising her and her father to allow us to break both her clavicles at the fulcrum point and then to force them to heal with an anterior curve or angle at that point. They consented and on March 6th, 1906, at the Owen Sound Hospital, Dr. Danard assisting and Dr. Cowper giving chloroform, I sawed nearly through each clavicle at a point one inch from the inner end so as to be about the middle of the costo-clavicular or rhomboid ligament which had half its fibres thus attached to each fragment, and bending back the shoulders broke the bones through. It was now impossible to produce dislocation, as we tried it on the table. The incisions were then sewed up and both healed by first intention. The shoulders were held back by figure-of-eight bandages and plaster-of-Paris dressings *in the utmost of the position that before this used to produce dislocation*, so that they healed with a considerable angle at the point of fracture. She was kept in bed four weeks.

As to the result I will again copy from a letter of her father dated May 15th, 1907, one year and two months after the treatment. "Since the operation her general health has been better than for fifteen years back. Before the operation she was usually sick, depressed, without appetite, and suffering from severe headache. She has none of these symptoms now. The right clavicle has never been dislocated since the operation. The left did dislocate two or three times immediately on leaving the hospital; twice at home since then; and latterly three partial dislocations—that is, the clavicle did not come out of joint entirely. The last of these took place on the 21st of Sept., 1906, eight months ago. Since then there has been no dislocation of either clavicle. She can now do any domestic work without pain or inconvenience—as pumping water (which she could not do for the last five and a half years); scrub and sweep floors; do ironing; make beds; wash clothes and put clothes on the line; sew; practise music on the piano; comb her own hair and dress. These could not be done by her formerly, or else caused her much suffering. The operation has been a complete success." In regard to the dislocations that occurred on the left side after the operation, I predicted to him that these would cease as soon as the provisional callus on the under side of the clavicle should be absorbed.

This little operation of fracturing the clavicle for dislocation of its sternal end is, I believe, an entirely new idea in the treatment of this disease. I have seen no suggestion of it in any treatise, text, paper, or discussion. It is a valuable addition to our resources in handling this distressing condition, a condition the treatment for which has resulted in failure in from 75 to 100 per cent. of the cases recorded. The good result arising from this operation is caused by the that the epidemiological data strongly support a relationship between human diphtheria and similar affections in the lower animals and that conversely the interchange of the disease between the lower animals and man explains many points in the epidemiology of diphtheria hitherto obscure and impenetrable.

As soon as we recognise the unity of the disease in man and in the lower animals we immediately understand its geographical peculiarities, its seasonal prevalence, its cyclic recrudescences, its rural distribution, its preference for the neighbourhood of water bodies, its progress along the direction of the prevailing winds, the frequent occurrence of cases in isolated farmhouses, in out-of-the-way places along the sea-coast, the greater prevalence among children, especially female children, the heavier toll it levies on mounted troops as compared with infantry, the connexion with manure, the recent increase in towns, the unimportance of geological, orographical, meteorological, and sanitary conditions. But to understand thoroughly all these facts we must, in the first place, recognise that as in plague and tuberculosis so in diphtheria the epidemiology of the disease is exceedingly complex owing to the wide zoological distribution of its causative agent and the various interaction of different animals brought about by variations in the specific organism which render it more or less adaptable to animals nearer allied to or further removed from the usual host species, just as in the case of the eel-worm aforementioned.

A certain number of epidemics have been traced to milk containing the specific organism. In most cases evidence pointed to the cow as the source of the infection; anyhow, the disease was thus traced from town to farm, and not infrequently at the farm either human beings, or cats, or swine, or poultry were found to be suffering from throat affections.

Other outbreaks limited to cavalry regiments or to certain stables and mews seem to indicate with equal suggestiveness the horse as the source of the disease in man; here also cats and poultry or sparrows seem to have suffered similarly at the same time. The prevalence of the disease in cattle and horses would explain the suspicion which has been so long and persistently attached to manure. Tissier[31] and Longuet[32] observed that in 40 per cent. of cases manure, on which diphtheritic fowls had been disseminating false membranes, was responsible for the diffusion of the disease. Dr. Newsholme and others have suggested that the diphtheritic germ might spend a stage of its life as a saprophyte in the soil, on manure, or on rags. I would draw attention to a possible rôle of the house fly in this connexion. Manure, especially horse manure is the chief breeding place of this insect. Countless numbers of its larvæ and pupæ may be found in every heap of manure, and it is for this very reason that fowls are attracted to manure heaps. Diphtheritic bacilli present in the manure from the horse or in the false membranes expectorated by the fowls may be ingested by the maggots and retained in a living condition within their intestines. We know that the bacilli of plague, tuberculosis, enteric, cholera, anthrax, &c., pass unharmed and may even be retained alive for weeks in the digestive tract of flies and other insects. Stiles placed fly maggots with some *Ascaris lumbricoides* and the latter were devoured; the eggs of the *Ascaris* were found not only in the fly larvæ but also in the pupæ and in the adult insects which developed from them. Evidently, then, the adult fly would serve as a disseminator of the parasite and if the eggs obtained the proper stage of development the fly might infect man directly by depositing them on articles of food.

The great frequency of diphtheritis amongst fowls, domestic pigeons, and certain game birds, such as pheasants and partridges, that are reared by the thousand in the neighbourhood of farms has long suggested the transmission of the disease from the farm birds to the farm mammals and either directly or through the latter to man. Finally, it is only reasonable to surmise that the farm birds, at any rate the farm pigeons, may contract the disease from the wild pigeons and more especially the wood pigeon or ring dove (*Columba palumbus*), the flocks of which are known to be subject to deadly epidemics of diphtheritis. The ring dove is generally distributed throughout Europe and is very common in Great Britain, having increased largely in numbers within recent years owing to the destruction of birds of prey, the increase of coverts and the great amount of land now planted with turnips and other green crops serving to supply it with food in the winter months. It collects in immense flocks in autumn, and in severe winters the local birds receive considerable accessions through migration either from the north or the continent. In October and November, 1884, the country between Berwick-on-Tweed and Yarmouth was greatly infested by migratory flocks and another large immigration was noticed in 1894. The steady increase in the number of wood pigeons during recent times, their greater abundance in the eastern districts, especially during autumn and winter, and their invasion of towns within recent years explain in a most remarkable way the rural distribution of diphtheria, its occurrence in isolated places, especially near the coasts or even in lighthouses, its greater frequency in the eastern districts of this country, its prevalence during the last quarter of the year, and its recent increase in towns.

Concurrently with the ring dove other *Columbidae*, such as the stock-dove (*Columba oenas*), have also to be considered as possible factors in the epidemiology of diphtheria. The stock dove has also greatly increased in England within recent years. In many parts of Central Europe this species is even more abundant than the ring dove. In this country it inhabits wooded crags in Wales, the cliffs of Dorset, some parts of Devon, Derbyshire, and even those near Flamborough Head in Yorkshire. In treeless areas, such as are met with in Suffolk, Norfolk, Lincolnshire, the East Riding of Yorkshire, Lancashire, Cumberland, &c., it deposits its eggs in rabbit burrows. This peculiar habit might suggest the transmission of diphtheritis between the bird and the rodent. Experimentation has shown that pigeon diphtheria can be transmitted to rabbits by inoculation. The distribution of the *Columbidae* as a group, their migratory habits, and the considerable increase of certain species in recent years are sufficient to explain the epidemiology of diphtheria, just as the distribution and migrations of rats explain the epidemiology of plague.

There is another bird which I should like to mention in connexion with diphtheria and that is the common quail (*Coturnix coturnix*). I am not aware that any one has ever reported the disease from this bird, but it belongs to the family *Phasianidæ* that includes fowls, turkeys, pea-fowl, guinea-fowl, pheasants, and partridges, all of which are severely affected. The quail is notable for its extended migrations. Its range is very great, for it extends throughout the whole of Europe, in Asia as far east as Japan, and in Africa as far south as the Cape Colony. Immense flocks annually visit the countries bordering on the Mediterranean, especially on the spring migration, when, as of old in Sinai, multitudes come up in the night and cover the land. The majority pass northwards though many remain to breed. In autumn, on the other hand, a considerable number sojourn in the south of Europe and the north of Africa, though the majority go further south, always travelling with the wind. In England the quail used to arrive regularly every spring and leave for the south in October; some remained throughout the year in mild winters. They used to be plentiful in Hertfordshire, Cambridgeshire, Suffolk, Norfolk, Lincolnshire, and Lancashire, and from time to time unusual influxes took place. In recent years the bird has become exceedingly rare in this country. There is a passage in the Bible (Numbers xi. 31–34) that I am greatly tempted to look upon as indicating not only the occurrence of diphtheritis in the quail but also its tranference from this bird to man. The text says:—

> 31. And there went forth a wind from the Lord, and brought quails from the sea, and let *them* fall by the camp, as it were a day's journey on this side, and as it were a day's journey on the other side, round about the camp, and as it were two cubits *high* upon the face of the earth.
>
> 32. And the people stood up all that day, and all *that* night, and all the next day, and they gathered the quails: he that gathered least gathered ten homers: and they spread *them* all abroad for themselves round about the camp.
>
> 33. And while the flesh was yet between their teeth, ere it was chewed, the wrath of the Lord was kindled against the people, and the Lord smote the people with a very great plague.
>
> 34. And he called the name of that place Kibroth-hattaavah: because there they buried the people that lusted.

Now, it seems to me that no other disease could explain more satisfactorily than diphtheria the plague implied in this passage. Diphtheria manifests itself in the very fauces, and the text seems to indicate this localisation in a figurative way by stating that the Lord smote "while the flesh was yet between their teeth." The flesh of the quail has often been looked upon as poisonous. Pliny ascribes its poisonous qualities to the birds eating hellebore and the seeds of other poisonous plants. The Arabian physicians proscribed its use. In many parts of Northern Africa, in chiefly because of the fear of infection and also because hæmorrhage was going on in the pelvis. The circumstances in which the rupture occurred were such as to make infection almost certain. The cottage was dirty, there were no towels, and there was only a limited supply of hot water. On this account neither the hand of the accoucheur nor the vulva of the patient was in an ideally aseptic condition.

---

[31] Revue d'Hygiène, 1887, p. 914.

[32] Ibid.

At 4 P.M. on July 5th, 1907, my partner, Dr. W. Blackwood, was urgently summoned to a multipara, aged 32 years, and living at a distance of three miles. The baby had been born one hour or more with the aid of the county nurse but the placenta was retained. On introducing his hand into the uterus through a rather contracted os Dr. Blackwood found to his horror that his hand was in contact with the intestines. After removing the placenta and giving ergot—the hæmorrhage not being excessive—he had the patient removed by ambulance to the Redruth Women's Hospital. At 7 P.M. I held a consultation with Dr. Frank Hichens of Redruth, when it was decided to remove the uterus. An injection of $\frac{1}{30}$th of a grain of strychnine was given. On opening the abdomen I found that the pelvis was full of clots and that a large rent extended from the cervix through the right broad ligament, passing in front of the uterine vessels. The ovarian arteries were tied on the uterine side to leave both ovaries and after ligature of the uterine arteries the uterus was removed above the cervix. A roll of gauze for drainage was inserted into the cervical rent to Douglas's pouch.

The patient's temperature was almost continuously between 99° and 101° F. from July 5th to 13th, the highest points recorded being 102·4° on the 10th, when there was a rigor lasting 15 minutes, and for the second time 102·4° on the 13th. From July 13th to August 8th it was usually between 98·4° and 100°. The gauze drain was removed on the 12th and the stitches were removed partly on the 17th and partly on the 19th. On August 3rd the wound was healed. Enemata containing two drachms of oil of turpentine were frequently administered during the progress of the case and small doses of sulphate of magnesium were also given by the mouth.

The patient's convalescence has been interrupted by vesical pain, doubtless due to adhesions, as they are rapidly improving and there is no cystitis. I fear if the course sometimes adopted of gauze-plugging the rent had been adopted the patient would have succumbed to septic peritonitis.

SECTION OF SURGERY.

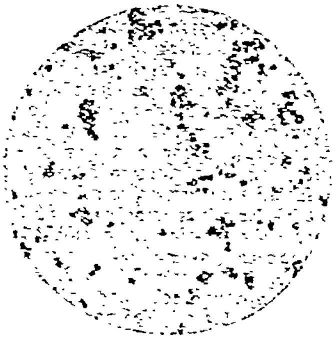
Tuberculosis Treated by Tuberculin.—Ureteral Calculus.

A MEETING of this section was held on March 27th, Sir HENRY R. SWANZY, the President, being in the chair.

Dr. FRANK J. DUNNE exhibited two patients who had suffered from Tuberculous Disease of Joints and had been treated by Denys's tuberculin. The first patient was a man, aged 39 years, who had been affected with a tuberculous ulcer of the lower third of the leg and ankle-joint for five years, as well as with several sinuses on both arms. An x ray photograph showed extensive matting and pulping of the bones of the tarsus. All discharge ceased early in September, 1907, and the patient had good use of his foot and both arms. The second patient, a girl, aged 20 years, suffered from tuberculous disease in the wrist for about three years and in both ankles for over two years. The wrist was scraped with little improvement. When treatment commenced this patient was very much run down. Her temperature varied from 100° to 102° F., her pulse-rate was 100, and her weight was 6 stones 3 pounds. All discharge ceased early in June and her temperature had not since then been above normal. An x ray photograph showed matting and pulping of every bone in the wrist-joint, yet the girl had good use of the hand and could walk perfectly. In both these cases treatment lasted for about a year. The man gained 1 stone 9 pounds in weight and the girl 3 stones 6 pounds. In both cases about 50 injections were given.—The PRESIDENT said that he had only used Koch's tuberculin T.R. It now appeared that Denys's tuberculin was a very effective preparation.—Mr. JOHN LENTAIGNE said that he had recently had a large number of cases of complete recovery from tuberculous disease, the time of which was measured by months, not by years, as in the cases exhibited. He appreciated the good work which had been accomplished by Dr. Dunne but he believed that the results would have been more quickly attained by surgical assistance. In assisting surgical treatment by tuberculin he had found that Koch's tuberculin had not to be given so often as Denys's. Perfect recovery had been obtained by gauging the injections by the opsonic index but it was a difficult method.—Professor E. J. MCWEENEY said that the method for obtaining Denys's and Koch's tuberculin was the same up to a certain stage. Both grew the tubercle bacillus on the surface of a broth containing 5 per cent. of glycerine and filtered off the bacilli. But Koch's method from that point consisted in evaporating the liquor of the culture to one-fifth of its original bulk, while Denys used it without reducing it in volume. The difference, then, was that Denys's tuberculin contained presumably toxic and presumably therapeutic materials which were easily destructible; these would be destroyed by boiling in Koch's tuberculin. The latter was more concentrated than Denys's but he was not aware of any difference in the dosage. Nowadays the tendency was to have a small dosage and to avoid producing a reaction in a rise of temperature; in Koch's old system a rise was considered necessary. He had lately been working with tuberculin in obtaining the ophthalmo-reaction. He used Koch's old tuberculin diluted to the strength of 2 per cent. This provided material for hundreds of patients at a cost of 8*s.* 6*d.* One drop produced the desired result. Contemporaneously with this he used the cutaneous reaction by inoculating both arms, the right arm with a drop of 25 per cent. of the old tuberculin and the left arm with 3 per cent. boric acid solution. In a couple of cases he thought that he noticed a marked therapeutic result from the method in the absorption of a pleural effusion and in two other cases there was a distinct improvement in the symptoms. As the result of his experience of the opsonic index he stated deliberately that, in his hands at least, he had never been able to convince himself that the errors of experiment did not outweigh the very slight differences from the normal obtained by means of the method, and he did not think he would attach any importance to opsonic indices obtained otherwise than by Sir A. E. Wright himself, his immediate assistants, or those who had worked for a prolonged period under his immediate supervision. He had treated a few cases in private for tuberculous glands in the neck and he did so deliberately without estimating the opsonic index. After the injections of bacillary emulsion the glands had a tendency to swell and afterwards they rapidly underwent diminution and practically disappeared.—Dr. DUNNE, in reply, intimated that he had too many calls on his time and too little assistance to be able to use the opsonic index. He was guided as to the dosage by the effect of the injection on the patient. That might be a temperature reaction or a local reaction, but as much as possible he avoided a temperature reaction. If there was marked reaction he either left a longer interval or reduced the dose. He quite agreed that operative treatment would in some cases materially hasten recovery. He had about 90 cases under tuberculin treatment and he found that he got the best results with small doses at short intervals. After three and a half years of using tuberculin he was firmly convinced that, so far as their present knowledge went, there was no treatment anything like equal to it for tuberculous affections, no matter where situated.

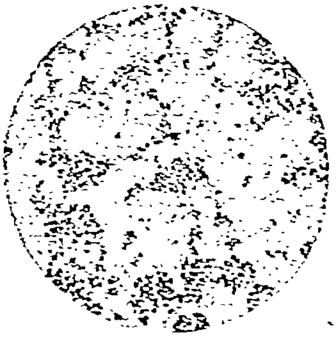
Mr. C. ARTHUR K. BALL read a paper on the Diagnosis of Impacted Calculus in the Ureter and gave an account of a case in which an erroneous diagnosis of impacted calculus in the ureter was made even with the assistance of an excellent radiograph taken with a shadowgraph bougie *in situ*. The case was that of a man who had been operated on elsewhere six months previously for renal calculus. Since the operation all the urine from that kidney came through a fistula in the loin. A shadow by the x rays of a supposed stone was found, apparently in the ureter; this was verified by several radiographs and the relation to the ureter established by use of a shadowgraph bougie. The ureter was exposed by an extraperitoneal iliac incision but no stone was present. The under the same pressure, the ozone took a longer time to reach the mouth and nose, and if the smell and taste were not so evident, this would point to some diminution in the size of the cavity and the calibre of the sinus. I say eventually because the first result, as will be seen, would probably be to facilitate the passage of the ozone into the mouth and of air through the external opening. The ozone was quickly smelt and tasted. At the end of the first week both passed more quickly and freely. This was an indication that the cavity was getting smaller. Gas under the same pressure will pass more freely through a tube that is interrupted by a cavity or expansion in proportion as the size of the cavity or expansion diminishes. During two days in the second week of treatment little or no air passed through the external opening and the ozone did not pass so freely into the mouth and nose. On June 13th the patient reported that air only passed through the sinus when he was lying down. On the 24th no air had passed through the sinus for three days. On July 9th the patient was cured and the external opening was closed. The treatment was carried out on 30 days during a period of seven weeks.

FIG. 1.



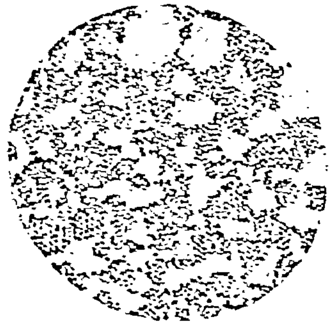
May 23rd, before treatment. 1. Streptococcus in large quantity. 2. Diplococcus in large quantity.

FIG. 2.



May 30th. 1. Streptococcus, large quantity. 2. Diplococcus, decreased quantity. 3. Staphylococcus albus and aureus, increased quantity.

FIG. 3.



June 23th. Staphylococcus albus and aureus, pure cultivation. An intermediate stage between Figs. 2 and 3, which is not shown by a photograph, showed: Streptococcus very few. Staphylococcus albus and aureus, largely increased quantity.

The bacteriological changes that took place in this case serve, I think, to confirm the views that I have often expressed: (1) Micro-organisms that are under healthy conditions good and useful will under unhealthy conditions become hostile; (2) that unhealthy micro-organisms require unwholesome matter for their nourishment; (3) that ozone and oxygen act by so changing and purifying the discharges that unhealthy micro-organisms, being deprived of the matter necessary for their existence, decrease and finally disappear; and (4) that oxygen and ozone have this effect on every micro-organism I have ever been able to discover in wounds or suppurating surfaces except the staphylococci, which under these conditions increase in number and often in size. These conclusions are the result of observations and microscopical examinations of the pus from some 500 cases treated with oxygen and ozone.

Bearing on the above conclusions, it is a significant fact connected with this case that the vaccine that produced such successful results was prepared from the staphylococci existing in the offensive and putrid discharge from the wound in a patient suffering from blood poisoning, yet in the same wound but under the influence of ozone and oxygen these very staphylococci steadily increased as the healing process proceeded, and were to me a clear indication that a healthy condition had been re-established and that cure would eventually take place.

Before commencing the treatment a specimen of pus was taken from the wound and a cultivation was made from it for microscopical examination. This was repeated at intervals during the treatment. The micro-photographs taken of the slides that were prepared show steady decrease and final disappearance of those micro-organisms that are hostile to healing, and a steady increase of the staphylococci which under the influence of ozone and oxygen always increase in number and often in size as the healing process proceeds.

Hertford-street, W.

ANTERIOR DISLOCATION OF THE STERNAL ENDS OF THE CLAVICLES: TREATMENT BY FRACTURE OF THE CLAVICLES WITH GOOD RESULTS.[1]

BY T. H. MIDDLEBRO', M.B. TOR., F.R.C.S. ENG.

I MAY first recall the anatomical outlines of the sternum. The upper end of the sternum is divided into three areas: a central, which is the interclavicular area, and two lateral ones, which are shallow depressions in which articulate the comparatively large inner ends of the clavicles. An inter-articular disc of fibro-cartilage lies in each joint, attached above to the clavicle and below to the lower margin of the joints. Each joint has an anterior sterno-clavicular ligament, a posterior sterno-clavicular ligament, and an interclavicular ligament. The strongest bond, however, holding the bones in apposition is the rhomboid or costo-clavicular ligament. This structure is short and strong, about one inch in breadth, and the centre of it is about one inch from the inner end of the clavicle, and its fibres pass downwards and inwards to the first rib or its cartilage. The sterno-cleido-mastoid muscle attaches to the anterior surface of the inner end of the clavicle.

An epitome of the opinions of some prominent surgical authors on the causation of this dislocation will show the arguments present in my mind when advising the treatment. Erichsen states that it is caused by blows on the shoulder, bending the shoulder forcibly back, or by violence to the elbow while the arm is raised from the side, and occurs spontaneously sometimes in lateral curvature of the spine. It is reduced by pulling the shoulder outwards and backwards while the elbow is in front of the mid-lateral line. There is a tendency to dislocate again. To lessen this tendency he uses a figure-of-eight bandage as in fracture of the clavicle to draw the shoulders well back and a large pad is for the symptoms. Nothing was found and the child died. On post-mortem examination a lepto-meningitis at the base of the brain was found. A caseous nodule of the size of a pea was found in the anterior part of the pons on the left side. Another similar nodule was found on the right occipital lobe just under the pia mater. The extension was probably by the blood stream.—Dr. John Rowan showed a number of stereoscopic photographs illustrative of External Diseases of the Eye prepared by the Lumière colour process. He pointed out that by this means they had a valuable method of recording the different stages of many diseases, more especially those of the skin.—The President described, with stereoscopic photographs, a very large External Fibro-cellular Tumour of the Nose.—Dr. Carl H. Browning read a paper on the Treatment of Trypanosome Diseases by means of Atoxyl and its Derivatives. The strain of trypanosomes chiefly employed was nagana, which killed white mice in three days. The injection of the largest safe dose of atoxyl cured only 8 per cent. With acetyl-para-amidophenylarsenic acid (a derivative of atoxyl synthesised by Ehrlich and Bertheim) over 93 per cent. were cured. Treatment was started 24 hours after inoculation. When only started 48 hours after, the atoxyl derivative must be given in repeated large doses. In advanced infections another method of treatment was by a combination of the most efficient drugs of different chemical types—e.g., acetyl-atoxyl plus trypan blue or by injection together with oral administration. The curative results are not due to an internal antisepsis in the ordinary sense of the term, as neither atoxyl nor trypan blue is trypanocidal in vitro. By treating infected animals with repeated small doses there was ultimately produced a trypanosome strain which was resistant to the largest doses of a drug of the same class. Thus an atoxyl-resistant strain was developed which could not be influenced by repeated large injections of the atoxyl derivative.

---

[1] A paper read before the Owen Sound Medical Society, Owen Sound, Canada.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 10th, Dr. W. Langdon Brown, the President, being in the chair.—The President showed a man, aged 34 years, with a Right Subphrenic Abscess which he was coughing up through his lung. A skiagram showed a bulging up of the diaphragm on the right side, and the area of dulness changed on the patient changing his position. The character of the sputum was that of "anchovy sauce pus" and gave the reaction for bile.—Dr. Leonard Williams showed: 1. A man, aged 31 years, with well-marked persistent Cardiac Arrhythmia. There were systolic and diastolic murmurs at the apex and the arrhythmia was caused by the interference to the function of conductivity, probably due to degeneration of the auriculo-ventricular muscular bundle of His. 2. A man, aged 64 years, who complained of tingling in both hands. There was a systolic murmur at the base due to chronic aortitis, and both radial and brachial arteries were definitely hard and tortuous, so the arterio-sclerosis going on evidently caused the tingling.—Dr. T. Grainger Stewart showed a married woman, aged 32 years, who for the past three months complained of "pins and needles" down the inner side of the left arm and pain in the region of the left scapula. The left arm was weaker than the right and the muscles of the arm and the interossei were beginning to waste. She also had slight numbness and weakness of the left leg. The left pupil and the left palpebral fissure were smaller than on the right side. On examination there was complete loss of all forms of sensation along the inner side of the left arm and across the chest and back corresponding to the area supplied by the first, second, and third dorsal nerves. Both knee-jerks were active but the left one soon got exhausted. The signs and symptoms pointed to pressure on the left pyramidal tract and the lesion was probably an endothelioma inside the neural canal involving the posterior roots, more especially the first, second, and third dorsals.—Mr. A. J. Kendrew (for Dr. E. Cautley) showed: 1. A woman, aged 68 years, with a Saccular Aneurysm of the Ascending Aorta. At the level of the second right interspace there were a patch of dulness, a well-marked thrill, and a loud systolic murmur. There was no difference in the voice, pupils, or pulses. 2. A man, aged 33 years, with an Aneurysm of the Ascending and Transverse Aorta. At the level of the second and third interspaces there were a patch of dulness and a loud diastolic aortic murmur. There were well-marked tracheal tugging and complete paralysis of the left vocal cord causing hoarseness and a "brassy cough." 3. A man, aged 49 years, with an Aneurysm of the Transverse and Descending Aorta. Systolic and diastolic murmurs were heard all over the præcordium. There was well-marked tracheal tugging but no paralysis of the vocal cords.—Dr. N. S. Finzi described the rapid cure of old-standing Varicose Leg Ulcers by the driving in of zinc ions with the galvanic current.—The following office-bearers were elected for the session 1908–09: President: Dr. A. Morison. Honorary secretary: Dr. David Ross. Honorary treasurer and curator: Dr. B. G. Morison. Council: Dr. W. Langdon Brown, Dr. J. R. T. Conner, Dr. Leslie Durno, Mr. G. Angus Hunt, and Mr. W. Campbell M'Donnell.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of the Pathological Section of this society was held on April 2nd, Mr. T. H. Bickerton, the President, being in the chair.—Dr. A. Nimmo Walker and Dr. W. L. Hawksley showed Films from a Fatal Case of Diphtheria of the Conjunctiva. The patient was a year old and death took place on the ninth day of the disease.—Mr. G. P. Newbolt showed a Section of a Tumour removed from a male, aged 50 years. The tumour began in the glands of the neck and grew on to the parotid gland. It had lasted two years. It appeared to be a sarcoma with large angular cells packed closely together without any visible stroma.—Mr. W. Thelwall Thomas and Dr. J. S. Rowlands showed: 1. Tumour of the Coccyx removed from a man, aged 45 years. The growth was firm and lobulated. Microscopically it consisted of spaces filled with large cells. It was probably associated with the post-anal gut. 2. Cylindrical-celled Carcinoma from the Humerus from a man, aged 53 years. It had caused spontaneous fracture. The primary source of the carcinoma could not be ascertained at present. 3. Early Tubercle of the Kidney removed from a patient, aged 28 years. The diagnosis rested on cystoscopic evidence and the presence of tubercle bacilli in the urine.—Dr. J. Owen showed: 1. A portion of Small Intestine with Multiple Diverticula. There were about a dozen in number, the largest capable of containing the whole thumb. They were situated close to the mesenteric attachment. The specimen was from a post-mortem examination of a man, aged 69 years, who had died from cerebral hæmorrhage. 2. A Heart from a child, aged four years. The pulmonary orifice was reduced in size and there were a patent foramen ovale and deficiency of the upper part of the interventricular septum.—Dr. Rowlands described an Analysis of 26 Renal Calculi. Only three contained uric acid. The others consisted of calcium oxalate. The external appearances were no guide to the chemical nature of the calculi. The calculi had been removed by Mr. Thelwall Thomas and the analysis carried out at his suggestion.—Dr. O. T. Williams read a paper on the Etiology of Appendicitis. He showed that appendix concretions were largely composed of calcium and saturated fatty acids, were concentrically laminated, and therefore formed *in situ*. The normal secretion of the appendix contained the same fatty acids as found in the concretions. The micro-chemical nature of the changes in the appendix mucous membrane was described. In cases of appendicitis there was even in children a large deposit of calcium soaps in the mucosa, in many cases almost a complete ring being laid down. This was quite sufficient to cut off the nutritive supply of the mucous membrane and thus to predispose to the invasion by micro-organisms. Slight amounts of free fatty acid were found in the submucosa and also to some extent the formation of calcium soaps in the mucous membrane. The relationship of the nature of the fat in the diet to this disease was discussed.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on April 1st, Dr. A. T. Wilkinson, the President, being in the chair.—Dr. A. A. Mumford related a series of cases illustrating the Influence upon the Growth of Children exerted by a Defective Metabolism of Fat when this was prolonged over a series of years. The condition described was associated with chronic diarrhœa and with absence or alteration of the pigment of the fæces (acholia). There was no concomitant jaundice or glycosuria. In the cases described improvement or cure resulted from the administration of pancreatin and the consequent assimilation of fat was secured after a treatment of coincident duodenal catarrh by mercurials, &c., had failed. Growth was resumed after it had been arrested for many years and at least in one case permanent cure resulted. After the cases had been described the relation of the condition to rickets and to interstitial pancreatitis was considered.—Dr. J. Dixon Mann described two ways in which, in the absence of jaundice, the fæces might be colourless for a considerable time—from excess of increased curve given to the clavicle at the point where it arches over the first rib, making it no longer possible, after the callus leaves, for the clavicle to lever on the rib; or is caused by the increased tension given to the rhomboid ligament by the new shape of the clavicle; or, more likely, the good result is due to both causes combined.

Owen Sound, Ontario.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HYPERTROPHY OF THE URINARY BLADDER IN A WOMAN WITH AN OVARIAN CYST.

BY JAMES OLIVER, M.D. EDIN., F.R.S. EDIN.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE, LONDON, W.

THE patient, aged 44 years, a widow, was the mother of two children, and the last child was born 23 years ago. Menstruation had recurred regularly and the monthly discharge was of the usual amount. About five months previously to seeking treatment the patient remarked that she had some difficulty in passing urine and this difficulty had been noted more or less ever since. It had never been necessary for her to have the urine drawn off. For a fortnight before I saw her she had observed that her abdomen was increasing in size and it was on account of this that she sought advice. She had complained of no pain practically.

Physical signs.—The anterior abdominal wall was pushed markedly forward by a large globular and cystic swelling which was located centrally and extended out of the pelvis. The summit of this swelling was felt two inches above the umbilicus. It was not in the slightest degree tender to the touch. At this stage I passed the catheter and drew off 75 ounces of urine. The patient alleged that she had passed a good quantity of urine only half an hour before seeing me. After emptying the bladder by the catheter the following physical signs were noted. The abdominal swelling previously referred to had disappeared. Palpation detected a small globular swelling in the right iliac region and a small, somewhat flat and firm swelling in the left iliac region.

Vaginal examination.—The posterior vaginal wall was thrust markedly forward by a firm swelling, the lower border of which was felt just within the entrance to the vagina. This swelling appeared to be continuous with the two iliac swellings. The cervix uteri was located *high and* was reached with difficulty. The body of the uterus could not be clearly defined. I came to the conclusion that the tumour was probably an anomalous fibroid of the uterus and advised its removal.

Operation.—On opening the abdomen mesially the bladder was found to be incorporated with the anterior abdominal wall from the pelvis to the level of a spot located midway between the pubes and the umbilicus. The summit of the bladder was located two inches higher. The bladder was so enormously thickened that grasped between the fingers it felt like a uterus and altogether it was rather larger than a normal adult uterus. On exploring the pelvis I detected a swelling of the size of a large cocoanut firmly fixed in Douglas's pouch. On separating the adhesions the tumour, which proved to be a cyst of the left ovary, burst. On account of the bladder it was awkward to transfix and ligature the left mesovarium. The right ovary was healthy. The uterus, which was of a normal size, could not be dragged higher than a spot about the level of the middle of the bladder.

On referring to hypertrophy of the bladder Hunter states that "in consequence of obstruction to the passage of urine, the bladder having more to do than common is almost in a constant state of irritation and action; by which, according to a property in all muscles, it becomes stronger and stronger in its muscular coat; and I suspect that this disposition to become stronger from repeated action is greater in the involuntary muscles than the voluntary; and the reason why it should be so is, I think, very evident; for, in the involuntary muscles the power should be in all cases capable of overcoming the resistance, as the power is always performing some natural and necessary action." It is very evident that Hunter and others since his time believe that hypertrophy of the urinary bladder can only result from some obstruction at the neck of the bladder or in the urethra. In the case which I have just recorded there was no evidence of any obstruction at the neck of the bladder or in the urethra. A No. 10 catheter was passed easily into the bladder. The resulting hypertrophy was no doubt connected with the way in which the bladder was incorporated with the anterior abdominal wall, and although the wall of the viscus was enormously thickened the expulsive power of the organ had not been correlatively increased. The association with an ovarian cyst was probably a mere coincidence and the cyst was probably not accountable for the hypertrophy of the bladder. In some cases this disorder may, in my opinion, be due to disease of the viscus itself.

Gordon-square, W.C.

HYDRONEPHROSIS OF HORSESHOE KIDNEY; NEPHRECTOMY; RECOVERY.

BY W. GIFFORD NASH, F.R.C.S. ENG.

A FEMALE, aged 16 months, was admitted into Bedford County Hospital on Oct. 23rd, 1906, with a history that six months previously her mother had noticed a lump of the size of a hen's egg in the left half of the abdomen, which had gradually increased without in any way affecting the infant's health. On examination the child was found to be well nourished and looked fairly healthy. In the left half of the abdomen a rounded swelling of about the size of a cocoanut could be felt. This fluctuated, felt elastic, and was moveable in all directions. It appeared to be attached to the left kidney by a sort of neck and had no pelvic connexions. It was not tender on manipulation. The right kidney could not be felt. Micturition was normal. The urine had a specific gravity of 1020, was faintly acid, and did not contain any albumin.

Operation.—On Oct. 30th a vertical incision was made over the front of the swelling and then it was seen to be a retro-peritoneal cyst arising from the left renal region. The peritoneum was closed and another incision was made at right angles to the first. A trocar was inserted and about half a pint of clear fluid was evacuated. The cyst was drawn up and with it the kidney, which was found to be the left half of a horseshoe kidney. The ureter was first tied and divided. At the junction of the two halves of the horseshoe kidney a white band could be seen. An incision was made through this and the cut capsule of the right kidney was united with catgut sutures. Lastly, the renal vessels which were abnormal were tied and the left half of the kidney was removed. The hydronephrosis chiefly consisted of a dilatation of the renal pelvis. The ureter was not dilated. A drain was inserted and the wound was closed. The fluid from the hydronephrosis had a specific gravity of 1010, was alkaline, and contained 0·1 per cent. of urea. The child made a good recovery, but owing to an attack of varicella remained in hospital until Dec. 8th. She has remained in good health.

Remarks.—This case is of interest for the following reasons: 1. The two kidneys were fused in the form of a horseshoe. Morris states that this malformation was found in 19 out of 18,244 cases—i.e., about once in a thousand. 2. The fused kidneys lay at a lower level than the normal kidneys. 3. The left half was hydronephrotic. The dilatation was confined to the pelvis of the kidney and appeared to be due to the angle at which the ureter entered it. 4. Nephrectomy of the left half of the horseshoe kidney was performed. Morris mentions the fact that a horseshoe kidney may be hydronephrotic but does not mention any case of nephrectomy for this cause. 5. The age of the infant was only 16 *months*.

Bedford.

NOTES ON A CASE OF RUPTURED UTERUS.

BY JOHN H. TONKING, M.B. LOND.

THE rarity of rupture of the uterus in general practice induces me to publish this case. Out of over 2000 labours this is the first case that I have seen. It therefore follows that the experience of the individual practitioner in such cases must be limited. The want of definite rules by authorities places a large margin of responsibility on the medical attendant. In this case the uterus was removed are also many seventeenth-century Dutch pictures showing the medical man of the time looking at the urine in the urinal. Dr. J. Tyson[1] of Pennsylvania says that albumin, or rather a substance coagulable by heat, was first discovered in the urine by Cotugno in 1770. On p. 6 Dr. Wainwright refers to "the red plague" or "the red pestilence" in annotating quotations from *Coriolanus* and *The Tempest* as being typhus fever. This disease was said to have been brought home by the English garrison of Havre where it raged in 1563. It was often confounded with true plague but by those who knew better was called "febris purpurea."

The arrangement of the book is good, the quotations being grouped under the headings of Medicine, Surgery, Mental and Nervous Diseases, Obstetrics and Midwifery, Therapeutics, Pharmacy and Toxicology, Anatomy, Physiology, Hygiene and Dietetics, Ethics, and Medical Jurisprudence. The volume is beautifully printed and bound and has as the frontispiece a photogravure from the portrait which was the original of the Droeshout engraving in the first folio edition, published by Heming and Condell, two of Shakespeare's theatrical colleagues. It is interesting to note that the quotations given are taken from an edition in the possession of Dr. Wainwright, printed in 1796 by Bellamy and Roberts, London, now out of print, and from a more modern one by Charles Knight.

Text-book of Ophthalmology. By Dr. ERNST FUCHS, Professor of Ophthalmology in the University of Vienna. Authorised translation from the eleventh German edition, with numerous Additions, by ALEXANDER DUANE, M.D., Surgeon to the Ophthalmic and Aural Institute, New York. Third edition. With 441 illustrations. London and Philadelphia: J. B. Lippincot Company. 1908. Pp. 908. Price 25*s.* net.

WE have long held that Fuchs's "Text-book of Ophthalmology" is the best of the larger text-books and we have yet to discover adequate reason for changing our opinion. Its chief excellencies appear to us to consist in the extraordinary simplicity and lucidity of its style, the masterly grasp of the subject, and the admirable proportion which is maintained between the several parts. Professor Fuchs possesses in a marked degree the capacity to see a subject whole and to this are added an unusual skill in exposition and felicity in expression. More than in any other text-book of ophthalmology with which we are acquainted the subject is presented in a truly scientific manner upon a sure basis of pathology. The student is not embarrassed by bald statements of isolated facts. A clear conception of the diseased condition is conveyed by careful attention to the prominent pathological features and the appropriate treatment is presented as a logical deduction. The more recondite discussions are not ignored but are set in proper perspective by relegation to paragraphs printed in smaller type. In this manner the broad outline is sharply emphasised and the shades of opinion serve but to throw it into relief.

The third edition of the English translation retains the excellencies of its predecessors. Professor Fuchs has elaborated several of the sections, notably those on glaucoma and sympathetic ophthalmia. As in previous editions the translator has made considerable additions, easily recognisable by inclusion between brackets. Of these the more important deal with disturbances of motility and the correction of refraction, subjects which are certainly somewhat neglected by continental clinicians. He has also added many illustrations. The additions are, on the whole, judicious but they have undoubtedly reached the limit of expediency. Amongst the new illustrations are coloured drawings of fundus conditions; they are all borrowed from other sources and are not of outstanding merit. The absence of coloured plates has been a defect of this admirable work but if they are provided they should be worthy of their setting.

Hospital Training-School Methods and the Head Nurse. By CHARLOTTE A. AIKENS, late Director of the Sibley Memorial Hospital, Washington, D.C., &c. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 257. Price 6*s.* 6*d.* net.

IN view of the numbers of nurses who yearly enter for training and of the importance of methodical arrangement for their instruction, it is surprising that more books dealing with methods of training have not appeared. There is perhaps a tendency to believe that the routine business of nursing can be picked up haphazard in the course of ward work and that instruction in the scientific principles underlying it is comparatively unimportant and can be inculcated in a few set lectures, probably given by a member of the hospital staff. That there are a good many problems involved in the arrangement of an ideal course of instruction for nurses will be apparent to the reader of the book before us, which is evidently written by one who has had practical experience in the matter and whose advice is well worth considering. Now and again in studying her instructions we are conscious that the American ideal of a nurse is somewhat different from our own, the tendency being there, so far as we can judge, to throw more responsibility upon the nurse and to encourage her to act upon her own initiative more than is expected or appreciated in this country. Still, the author does not approve of nurses being compelled to "spend 24 class periods in a pathologic laboratory making a careful study of the more common pathogenic organisms, such as the tubercle bacillus, the pneumococci and gonococci, and the germs of typhoid fever, diphtheria, and tetanus, as one modern training school requires." She appears to think, however, that the nurse should be prepared to criticise a medical man's prescription if he orders too large a dose of a drug. On the whole, we find the advice given pre-eminently sane and helpful. Common sense and cleanliness and cookery are allowed to rank in importance before the theories of chemistry and bacteriology. The matter of the training of nurses is considered both from the point of view of the probationer and of the ward sister and matron and many sensible hints are given which may be commended to the attention even of the physicians and surgeons who lecture to nurses. Specimens of examination papers are given and also a scheme of instruction calculated for the different years of a nurse's training. Anecdotes illustrating "how not to do it" are also narrated. A valuable chapter points out the high qualifications demanded of a district nurse who has a much more difficult part to play than the nurse who does her work amid the conveniences of a well-equipped hospital. In short, we can heartily commend the book to the attention of all who have to do with the management and teaching of nurses as a mine of information and ideas which cannot be read without profit.

Essentials of Human Physiology. By D. NOËL PATON, Professor of Physiology, University of Glasgow. Third edition. London and Edinburgh: William Green and Sons. 1907. Pp. 477. Price 12*s.* net.

THE original character of this text-book has been preserved. In the present edition several parts have been rewritten—for the second edition appeared in 1905—more especially dealing with the proteins, classified as simple, conjugate, and scleroproteids, to which about six pages are devoted in an introductory section on protoplasm, with references to more detailed treatment in the later part of the text; with Sherrington's work on the integrative action of the nervous system, and H. Head's investigations on cutaneous and deep sensibility. There are some other changes in connexion with the measurement of the arterial blood pressure in man and the newer ureter was dilated and the final result was satisfactory. The origin of the shadow, which is still present, has not been established. Mr. Ball said the mistake could only have been avoided by a stereoscopic radiograph taken with a shadowgraph bougie *in situ* and that in future he intended to make use of this method in all similar cases.—Mr. WILLIAM I. WHEELER said that the case had been formerly in his hands and two x ray photographs verified the diagnosis of renal calculus. After the stones were removed a catheter was passed into the bladder and every care was taken to see that no calculus remained in the ureter.

---

[1] Bright's Disease and Diabetes, London, Rebman, 1904.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held on April 3rd, Dr. J. Constable (Leuchars) being in the chair.—Mr. D. M. Greig showed a case of Sporadic Cretinism in a female, aged 11 years. The case was typical of the condition and presented that peculiar and characteristic physiognomy of apathy, with heavy stunted body, bent limbs, and awkward waddling gait. The head was unusually well covered with hair and there were well-marked supraclavicular pads. He also showed a woman after two operations of Partial Craniectomy for Osteitis, who suffered before operation from exceptionally severe headache, evidently caused by the pressure of the thickened bone, the removal of which gave relief. The pieces of the bone removed and stereoscopic photographs of the patient before and after operation were exhibited. He then showed two cases after Nerve Suture, the first after primary suture of the median nerve, cut at the wrist, and the other after secondary suture of the ulnar nerve, cut at the elbow.—Dr. A. McGillivray showed a man who, while at work in a foundry, received an injury to his eye, causing a punctured wound of the cornea which produced a traumatic cataract. When the lens was removed it was seen that the foreign body, a small piece of steel, was implanted in the optic disc.—Mr. A. Don showed a case of Early Aortic Aneurysm with an x ray photograph of the condition. The outstanding clinical feature of the case was the loudness of the murmur which could be easily heard without the aid of a stethoscope while standing beside the patient.—Dr. W. E. Foggie showed a boy with a Patch of Favus in the Right Axilla. There was no sign of the disease on the head or on any other part of the body.—Mr. Greig exhibited a pelvis from an adult female showing Double Congenital Dislocation of the Hip. The acetabula were shallow and triangular in shape and there was a depression in the right ilium caused by the head of the femur. Many years ago the case had been diagnosed as osteo-malacia and had been treated by removal of both ovaries. This was in pre-x-rays days, with the advent of which the true condition of affairs was discovered. He also exhibited a Skull with Synostosis between the Atlas and the Basioccipital.—Dr. McGillivray showed a specimen of an Enucleated Eye after Penetration by a Lead Pellet, which was implanted in the intravaginal sheath of the optic nerve just behind the eyeball.—Dr. C. Kerr showed a Heart with Congenital Malformation from a child, aged 12 weeks. The usual symptoms were present in life. The heart consisted of a greatly dilated right ventricle and auricle. The pulmonary artery was stenosed and almost obliterated; from it was seen arising the ductus arteriosus, evidently patent. The cusps of the pulmonary valve were represented by three minute nodules. The aorta arose from the right ventricle and also from what represented the left ventricle, a mere slit in the hypertrophied ventricular wall, which would contain no more than ten drops of blood. The mitral valve was present but in miniature, and the opening led into a small depression of the size of a split pea, evidently the left auricle, separated from the right auricle by a very thin perforated wall. The aortic and tricuspid valves were normal. To all intents and purposes the heart was a two-chambered one, the left side of the organ being crowded out of any useful existence.—Dr. R. C. Buist showed a Liver with Acute Yellow Atrophy from a case of eclampsia.—Dr. G. A. Pirie showed radiograms from a case of Œsophageal Stricture caused by an intrathoracic tumour, the condition being well demonstrated after the patient had partaken of a bismuth meal.—Professor E. Waymouth Reid gave a demonstration of Colour Photography as Applied to Medicine. He described the technique of the process and exhibited many beautiful slides of pathological, physiological, and botanical specimens, both macroscopic and microscopic.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 2nd, Dr. George Williamson, the President, being in the chair.—Dr. A. T. G. Beveridge described a case of Empyema and Gangrene of the Lung and demonstrated the patient. A preliminary exploratory puncture revealed the presence of pus in the pleural cavity. A rib was therefore resected and a large quantity of fœtid pus was evacuated with but little improvement in the condition of the patient. A fortnight later there was a severe hæmorrhage from the wound which ceased spontaneously. Three days subsequently a gangrenous slough of lung tissue of the size of a Brazil nut was expelled through the wound. The patient is now (three and a half months after the operation) in perfect health.—Dr. J. Mackenzie Booth showed a patient 13 years after tracheotomy for Laryngeal Stenosis. The stenosis was due to a cicatricial web in the plane of the vocal cords with a small opening in it of about the size of a crow quill. Tracheotomy had to be done hurriedly owing to collapse of the left lung. The patient shows well-marked signs of specific rhinitis with extension to the ears and consequent deafness. His voice is exceedingly husky and he suffers from considerable discomfort from the tracheal aperture.—Dr. John Gordon described a case of Severe Vesicular and Bullous Eruption resulting from the application of a proprietary ointment. He also read notes upon two cases in which the external application of Cantharides for Sciatica had been followed by severe renal symptoms resembling those of renal calculus. In the first case a cantharides plaster had been applied for from two to three hours without the production of redness or vesication upon two different occasions. Curiously enough the pain in each instance affected the kidney of the side opposite to the application. In the second case the symptoms followed the application of a proprietary preparation of cantharides and capsicine.—Mr. H. M. W. Gray and Dr. J. R. Levack exhibited lantern slides of skiagrams and of skiagraphic tracings illustrative of Mr. Gray's paper upon the Functions of the Stomach and the Operation of Gastro-enterostomy, published in THE LANCET of Feb. 22nd, p. 549. They also demonstrated by means of the x ray screen the stomach outlines of persons who had taken a meal mixed with carbonate of bismuth. Five cases were demonstrated in this manner—viz., three normal stomachs and two stomachs after gastro-enterostomy. They also showed lantern slides of skiagrams illustrating Beck's method of treating old-standing sinuses by the injection of a mixture of bismuth and vaseline. The slides, which included cases of psoas abscess and hip-joint disease, with perforation of the acetabulum, showed very clearly the manner in which the bismuth mixture mapped out the various recesses of the sinuses. Mr. Gray had formed a favourable opinion of this method of treatment.—Dr. W. I. Fortescue showed Skiagrams illustrating the method of "Plastic Radiography." From the original skiagram negative a transparency was prepared. The two plates were then superposed and a second transparency was printed off. The two transparencies were next superposed and a final print was taken. The method consisted essentially in heightening the lights and darkening the shadows, and the final print thus obtained displayed a certain amount of perspective. Dr. Fortescue did not think that the results were so trustworthy as those obtained by stereoscopic radiography.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. J. Walker Downie, the President, being in the chair.—Dr. W. B. I. Pollock showed a case of Telangiectases of the Retinal Capillaries and Venous Radicles. Examination of the right eye showed a marked sclerosed condition of the branches of the superior retinal vein and groups of convoluted vessels. Four telangiectases were also seen. They had undergone no alteration during the past six months and on careful focussing the outline of small vessels could be made out.—Dr. J. Kerr Love reported a case of Aural Tuberculosis ending fatally. There had been an offensive discharge and facial paralysis had ensued. The mastoid process was filled with broken-down bone, granulation masses, and caseous material. Caseous glands in the neck were curetted. For a year the child remained well till symptoms pointing to meningitis developed—stupor, subfebrile temperature, fits, dilatation of the right pupil, and slow pulse. A loose fragment of bone was removed but there was no discharge. Coma deepened and the pulse and temperature returned to normal. The middle and posterior fossæ of the skull were opened on the possibility of there being an abscess to account

THE LANCET.

LONDON: SATURDAY, APRIL 18, 1908.

Tuberculosis of the Kidney.

MR. CHARTERS J. SYMONDS could hardly have chosen a more interesting or a more important subject for his Lettsomian lectures than Tuberculosis of the Kidney,[1] and his lectures were no mere summary of the current teaching of the day but based as they were on a series of cases carefully observed and treated they must advance our knowledge of the surgery of this disease. There were three matters which were specially brought forward by Mr. SYMONDS: the first was the great value in the early diagnosis of tuberculosis of the kidney of cystoscopy and other recent diagnostic methods; the second was the importance of the tuberculin treatment of small renal and vesical foci of tuberculosis when that treatment is controlled by opsonic estimations; and the third was the need for early removal of the kidney in suitable cases of tuberculous infection. Cystoscopy has proved of even greater value in diagnosis than was imagined by those who introduced the instrument and first employed it. It is as essential for the diagnosis of various vesical and renal conditions as is the ophthalmoscope in diseases of the fundus oculi and brain or the laryngoscope in diseases of the larynx. It is necessary, however, that the observer should be skilled in the use of the instrument, and this applies equally to the ophthalmoscope and to the laryngoscope. It is easy to misinterpret the cystoscopic appearances and therefore constant practice is necessary in order to obtain the fullest information. Mr. SYMONDS suggests that most surgeons should rely for information and guidance in this matter upon those who are specially skilled in the use of the cystoscope. As he says, it is easy to recognise gross changes and to see a calculus, but to pronounce from the appearance of the ureteric orifice that one or other kidney is in a sufficiently morbid state to demand its removal requires more than a casual acquaintance with this mode of examination. The cystoscopic view may reveal one ureteric orifice perfectly healthy and may show flowing from it a clear, rapid stream of urine—so far as this observation goes that kidney and ureter are healthy; while the lips of the orifice of the ureter of the other side may be seen to be swollen, puffy, and ulcerated, and it is noticed that from it flows a sluggish, cloudy stream of urine, then the surgeon can be certain that disease exists in the kidney and ureter of that side. The cystoscope may also show numerous tubercles around the affected ureteric orifice and perhaps tuberculous ulcers near. The value, then, of a cystoscopic examination by a competent observer is very great and it fails only in giving an exact estimate of the relative functional activity of the two kidneys. This information is best obtained by the use of the urine segregator, for there is a certain element of risk of conveying infection in the employment of ureteral catheterisation.

In very early cases where only a little pus and albumin are present in the urine, and even lumbar tenderness may be absent, the examination of the urine for tubercle bacilli after centrifugalisation is of the utmost importance and Mr. SYMONDS suggests that some of the slight cases of albuminuria which recover under general hygienic treatment may really be instances of very early renal tuberculosis. The matter can only be settled by the systematic examination for tubercle bacilli in all such cases. The matter is of some importance, for the question naturally arises, Is it justifiable to remove a tuberculous kidney when tuberculous foci are left in the ureter and bladder? Experience has shown that when the primary infecting source has been removed there is a tendency for these secondary foci to obsolesce and this tendency to recover is greatly aided by the tuberculin treatment employed under the control of the opsonic index, and several of Mr. SYMONDS's cases have shown the benefit of this treatment. The tuberculin treatment is best suited for those cases where the disease is not extensive, such as those in which the tuberculous kidney has been removed but a portion of the affected ureter remains, as does some slight tuberculous affection of the bladder. In one case which Mr. SYMONDS described the cystoscopic examination gave no indication of renal disease but showed some marked ulceration of the bladder; tuberculin treatment failed to heal this but improvement followed after the removal of the kidney which was extensively diseased. It has been shown that until late in the disease renal tuberculosis may be confined to one kidney and on this fact rests the justifiability of the operation of nephrectomy. The surgeon must, however, be clear that the opposite kidney is healthy and capable of carrying on the renal excretory function, and he can generally make certain of this by the use of the cystoscope and the urine segregator. When, however, the data are not sufficient to justify a certain opinion, nephrotomy offers a chance of relieving the symptoms and at the same time affords an opportunity of deciding definitely the amount of urine secreted by each kidney. Should the result prove that the other kidney is functionally efficient the removal of the diseased organ may follow as soon as the general health will permit. This form of nephrectomy *à deux temps* is also advisable when the surgeon thinks that the patient cannot stand the complete operation at once. The nephrotomy will suffice to put an end to the pyrexia caused by toxic absorption, it will stop the infection of the ureter and bladder if the lumbar drainage is free, and it will give time for improvement of the general health. Still, if the patient can stand it, nephrectomy at one operation is preferable, for nearly the whole of the tuberculous disease present is removed at once.

An important question arises, What is to be done with the ureter? Whenever the disease of the kidney is at all extensive the ureter is sure to be affected also and the disease of the ureter is often visible by the cystoscope. In several of Mr. SYMONDS's cases the ureter was left, yet recovery followed, but he considers, and we agree with him, that it is well to remove the affected ureter in those cases in fat and from over-reduction of the bile pigment. The fat cleavage in the intestine might be defective owing to absence of the pancreatic juice. It might also be impaired by chronic intestinal catarrh. In such cases the fæcal fat might reach from 50 to 80 per cent. When the amount of fat was very excessive the pigment present in the motions was obscured, their appearance then being quite pale, or they might even be devoid of all colour. In other cases the colourless stools were due to the bilirubin having undergone excessive reduction on account of inordinate putrefactive processes in the upper part of the large intestine. Under normal conditions the bilirubin was reduced by the intestinal bacteria to urobilin, to which the normal colour of the fæces was due; if the reduction was carried beyond this stage the colourless chromogen, urobilinogen, was produced and the fæces were then deprived of their natural pigment. Such changes occurred in chronic intestinal catarrh, in tuberculosis of the abdominal viscera, in septic diseases, and also in some blood diseases.—Mr. M. J. Chevers read a paper on the Etiology of the Psoriatic and Allied Conditions. The paper gave several arguments in favour of the neuropathic etiology of psoriasis, eczema, pemphigus, and angio-neurotic œdema, and explained that the exudation in the latter three as compared to the dry scaliness of psoriasis depended on the individual peculiarity with respect to the permeability of the capillary walls, the degree of coagulability of the blood, and the variability of skin elasticity. Mr. Chevers thought that these troubles should not be classified as diseases originating in the skin but as objective symptoms of general functional disturbance.

---

[1] THE LANCET, March 21st and 28th, 1908.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 8th, Dr. H. Waldo, the President, being in the chair.—Mr. W. Sampson Handley gave an address on Breast Cancer in Relation to the Lymphatic System, in which he propounded his views on the spread of cancer and explained his reasons for believing that secondary deposits were not the result of haphazard lodging of the cancerous emboli, but were subject to definite laws which he summed up under the permeation theory of dissemination by the lymphatics. He also described his method of treating lymphatic œdema by insertion of silk threads subcutaneously.—Mr. E. W. Hey Groves, in discussing the address, inquired whether there was any method by which the microscopic growing edge of the outward spreading lymphatic permeation of cancer cells could be determined or approximately located during life.—Mr. W. Roger Williams subjected to critical examination Mr. Handley's proposal to substitute "lymphatic permeation" for embolism as a general theory of dissemination. He considered that such a claim went far beyond what was justified by the ascertained facts. Restricted to local dissemination he thought that Mr. Handley might fairly claim to have captured most of the field for "lymphatic permeation"; and it was in this direction that valuable permanent results had been obtained. With regard to lymph gland dissemination and metastasis Mr. Williams thought that the facts adduced by Mr. Handley in favour of "lymphatic permeation" were far from conclusive; while in favour of embolism there was an immense mass of detailed evidence the cumulative effect of which was overwhelming.—Mr. T. Carwardine spoke of the practical surgical application of Mr. Handley's researches and asked whether in those cases of mammary cancer in which there was obvious enlargement of the supraclavicular glands there was also direct epigastric permeation into the upper abdomen, and, if so, which was likely to be the more advanced. For it seemed to him that operation might be contra-indicated by the presence of secondary glands in the supraclavicular fossa.—In reply Mr. Handley, among other remarks, said that he did not recognise a difference between local spread and metastasis, and brought forward the suggestion of "transcœlomic implantation" to explain some instances of remote metastasis. He did not deny that occasionally cancerous embolism might occur, but he was anxious to displace this as the chief part for metastases.

THE APPOINTMENT OF DR. J. T. C. NASH AS MEDICAL OFFICER OF HEALTH FOR THE COUNTY OF NORFOLK.—Dr. J. T. C. Nash, medical officer of health of the borough of Southend-on-Sea, whose eccentric treatment by his authority was recently noticed in our columns, has been appointed first medical officer of health for the county of Norfolk, where, we feel assured, his energy in preserving the public health and in forwarding the aims of the county council in this direction will be well employed.

Reviews and Notices of Books.

The Medical and Surgical Knowledge of William Shakespere. With Explanatory Notes. By JOHN W. WAINWRIGHT, M.D. New York: Published by the Author. 1907. Pp. 78.

American and Canadian literary men have ever been ardent admirers of Shakespeare and have frequently testified to this admiration in a practical and substantial manner. The works of Shakespeare have been discussed from almost every conceivable standpoint and many works have appeared dealing with his medical and surgical knowledge, notably one by Moyes first published in 1896. A student, nay, even a casual reader, of Shakespeare cannot fail to be struck with his numerous references to matters medical and surgical, displaying indeed a more or less intimate acquaintance with the medical lore of the times in which he lived. Of course, as is rightly pointed out by the author, Shakespeare wrote with a surprising amount of knowledge upon a variety of subjects of a widely different nature. He shows a wide acquaintance with law and theology, as well as mathematics, astronomy, and literature, and was mentally master of all time. It is not then a matter for much wonder that his writings in regard to medicine and surgery are distinguished by a similar far-reaching knowledge. All references relating to medicine are not given by Dr. Wainwright but only those which have appeared to him to possess the most interest. In those instances in which the meaning is obscure the doubtful points are elucidated by notes. The quotations are well chosen and the accompanying notes are in general useful. The work as a whole is instructive and ingenious and bears obvious marks of having been put together by a careful student of Shakespeare who at the same time was versed in medical and surgical affairs.

We must, however, take exception to Dr. Wainwright's note (p. 18) on the well-known passage from King Henry IV., Act 1, Scene 2, in which Falstaff asks the page, "What said the doctor to my water?" to which the page replies, "He said, Sir, the water itself was a good healthy water; but for the party that owned it he might have more diseases than he knew for." Here Dr. Wainwright says, "The value of urinary analysis was known centuries before Shakespeare's time." Analysis, however—that is to say, chemical analysis, or the separating the constituents, normal or abnormal—except by simple sedimentation of urine, was not known or practised until after Shakespeare's time. True, mediæval and sixteenth and seventeenth century books upon medicine are full of directions for the examination of the urine by *inspection.* For instance, the celebrated ninth-century writer, Isaac, whose works were translated from the Arabic into Latin by Constantinus Africanus (*circa* 1050), has left us a section, De Urinis, in which all kinds of indications are to be drawn from the colour, the smell, the taste, the "*complexio,*" and other characteristics. A fine edition of Constantinus's translation was printed at Lyons in 1515. He, or Isaac, mentions heating the urine. To come down to later times, Willis (1684) knew that turbid urines sometimes cleared up on heating and sometimes not, but analysis in any modern sense was of still later date.

Moreover, the delightful *Cautelae Medicorum* given by Arnold de Villa Nova, *circa* 1300 (Basle edition, 1585), p. 1454, show that the mediæval physician was quite aware that inspection did not give much information and that a judicious questioning was much more valuable. To come down some 700 years later than Isaac, Robert Recorde in 1599 printed a curious little book called "The Judiciall of Urine," which is mainly borrowed from mediæval writers and gives much the same instructions for the inspection. There likely to exert in the diminution of infantile mortality and also, which is perhaps even more important, in promoting the physical and intellectual welfare of the children who survive; and we see every reason to believe that the views so well advocated by Dr. THRESH are as sound economically as they are when regarded under their sanitary aspect. It is certain that there are dairies in which proper precautions with regard to cleanliness and water-supply are even now enforced and which nevertheless yield satisfactory profits to their proprietors. With regard to the cost of refrigeration Dr. THRESH points out that it would be easy for the smaller dairy farmers of any locality to unite their forces for the purpose, and that the supply of refrigerating railway vans has long been in operation in many foreign countries.

If the Bill promised by Mr. BURNS should be found on its introduction to be based somewhat upon the lines which Dr. THRESH has laid down, it should, we think, receive favourable consideration from the trade as well as from the public. The chief difficulty of enforcing its provisions would probably be found in the passive resistance to cleanliness of workpeople long accustomed to the conditions of filth which now prevail in dairies rather than in any increase of cost or diminution of profits. What these conditions of filth are may be read in almost every report issued by the Local Government Board concerning the sanitary state and administration of any country locality; and the details are usually so disgusting as to deprive us of any temptation to dwell upon them. It is certain that the customs in this respect which now prevail can only be overcome by great determination and continuous and close supervision on the part of employers who should, of course, be made responsible for any negligence which they permit. The Parliamentary opposition most to be dreaded is, we fear, that which will arise from interests which will be really imperilled and which will be imperilled because their continued prosperity is incompatible with the public welfare.

The Treatment of Soldiers Invalided for Tuberculosis.

THE committee appointed by the War Office "to consider the care and treatment after discharge from the army of soldiers invalided for tuberculous disease" has issued a preliminary report describing in outline a scheme which it puts forward for dealing with the matter. The committee, which consists of Surgeon-General Sir A. H. KEOGH, K.C.B., Lord LUCAS, Lieutenant-Colonel J. E. B. SEELY, D.S.O., M.P., Sir J. BATTY TUKE, M.P., and Mr. T. SUMMERBELL, M.P., with Colonel Sir E. W. D. WARD, K.C.B., K.C.V.O., as chairman and Mr. H. W. MOGGRIDGE of the War Office as secretary, has heard the evidence of a number of expert witnesses and has come unanimously to a general conclusion. Under the method at present in existence it is laid down that in the case of soldiers suffering from tuberculosis of the lung they shall be at once discharged from the army and sent to their own homes as soon as they are fit to travel, all responsibility in regard to them being then disowned. They are not awarded any pension unless they have earned it by length of service or unless it can be proved in any particular case that the disease was due to service or climate. The reason given for this regulation was the necessity that men suffering from the disease should be removed from contact with other soldiers, and it was found that its adoption was followed by a great reduction in the proportion of cases of tuberculous disease in the army; and the committee strongly upholds the necessity of so removing the patients. It points out that in practice the stringency of this regulation has been greatly mitigated, since the patients have usually remained in military hospitals under proper care and with adequate precautions for periods varying from four to six months, and have subsequently in many cases been sent to civil institutions through private or regimental charity. The committee is of opinion that the State should admit responsibility for the men and that suitable treatment should be organised. It supports this opinion not so much on the claims of the patients themselves as on the necessity for avoiding the danger to the civil population entailed by the discharge to their own homes of men suffering from a disease with which they are likely to infect others.

Having arrived at the conclusion that the State should afford means of treatment the committee has discussed two alternative methods for so doing, the first of which was the foundation of a central military sanatorium to which all the patients should be sent for treatment. This proposal the committee rejected after careful consideration on the following amongst other grounds. The results in America of a similar expedient have not been very successful, the benefit derived by the patients being markedly less than that obtained in the majority of civil institutions. It was calculated that the cost would not be less than that of the alternative proposal to be described below and that there would be in addition the large initial outlay necessary for buildings and equipment. It was further considered undesirable to augment the Royal Army Medical Corps by the addition of a staff of specialists in sanatorium treatment as would be a necessity if the proposed central institution were to be carried on to the greatest advantage. The proposal put forward by the committee as the best solution of the problem is that the army should make use of the rapidly increasing number of civil sanatoriums and that some of these institutions should be approached with the request that a certain number of beds should be reserved for the sole use of the army. It has some reason to hope that a sufficient number of beds will be obtainable in this manner to afford treatment to all soldiers who require it for a period of from three to six months. Under this scheme all soldiers who were *suspected* (the word is italicised in the report) to have tuberculosis would be at once removed from the military hospital, each being sent to the sanatorium nearest to his own home at which a bed was available. They would, as at present, be at once discharged from the army and would return to their homes after their period of treatment at the sanatorium and they would not be allowed to re-enlist. It is admitted that on this scheme those cases in which the disease had reached an advanced stage before it was detected would require to be dealt with separately owing to their being ineligible for sanatorium treatment. It is stated that such cases are rare in the army and it is proposed that efforts should be made to get such patients views on the digestion and absorption of proteins in the alimentary canal. In most other respects these "Essentials" are much the same as in the previous edition which was reviewed in THE LANCET of Oct. 21st, 1905, p. 1188. We shall only refer to the chief changes.

Some new illustrations and diagrams are introduced; some of the former are taken from Sherrington's work and one on neuro-muscular mechanisms in relation to reflex action is from McDougall's elementary work on psychology. The terminology as to reflex and other nervous actions adopted is that based on sensory surfaces as receptor fields, and so we have extero-ceptive stimuli which may be either noci-ceptive or non-injurious, intero-ceptive, and proprio-ceptive. There is a short account of Head's work on protopathic and epicritic sensibility which appeared in *Brain* in 1905.

About 35 pages are devoted to the master tissues (muscle and nerve) in contradistinction to the vegetative tissues (epithelium and connective tissue). In speaking of "heat production" (p. 42), we are told "but the heat evolved during rest of muscle is trivial." A figure of Erlanger's apparatus for determining the blood pressure in man is introduced. In dealing with the "starting mechanism of contraction," i.e., of the heart (p. 261), after noting the effect of galvanic shocks upon the isolated apex of a heart, it is stated that "if a stream of blood is passed through it, it will start contracting regularly and rhythmically." It might be well to indicate the part which internal pressure plays in the process. The diameter of capillaries is given but not their length. Perhaps the student would get a better grasp of one of the problems in relation to absorption if in addition to stating the length of the small and large intestine some data were introduced to show how the *valvulæ conniventes* on the one hand and the villi on the other enormously increase the superficial area both for absorption and it may also be for excretion. There is a short appendix dealing with some elementary facts of organic chemistry.

The work deals only slightly with histology and is illustrated by 181 figures in the text—some anatomical, a few histological, others of apparatus, and a number of excellent elementary diagrams. It is concise, lucid, and not too discursive, and should form an admirable introduction to the study of physiology by medical students.

LIBRARY TABLE.

Immuno-Chemistry. By SVANTE ARRHENIUS. New York: The Macmillan Company. 1907. Pp. 309. Price 7*s.* net.—This book deals with the methods of physical chemistry in their application to the study of the theory of *toxins* and antitoxins and is therefore calculated to be a scientific contribution of some importance in regard to the nature and treatment of disease. As is known, there have existed two schools of opinion in regard to the interaction of toxin and antitoxin. On the one hand, the German school, led by Ehrlich, maintained that the reaction was chemical in its nature; on the other, the French school, led by Metchnikoff, ascribed the effect of an antitoxin to purely physiological action. Professor Arrhenius adheres to the chemical view, although he admits that he cannot say that the arguments of Ehrlich are quite convincing, "since the erythrocytes may well be regarded as 'living,' even after their separation from the blood of an animal." The fact, however, that approximately the *n*-fold quantity of a toxin requires the *n*-fold quantity of antitoxin for its neutralisation is more certain ground in favour of the chemical hypothesis, and this has led to its general acceptance. Professor Arrhenius has worked hard at the subject and amongst other things has tried to show that the phenomena observed might be explained in the case, at all events, of the diphtheria toxin on the supposition that that toxin is a simple substance which slowly decomposes into an innocuous material that still neutralises antitoxin. These lectures on the immunity reactions were delivered at the University of California during the summer of 1904 and they put forward in an explicit way the contentions of the various workers in this field. The title, "Immuno-Chemistry," embraces the chemical reactions of the substances that are produced by the injection of foreign substances into the blood of animals, i.e., by immunisation. These substances are considered, therefore, in the book before us in regard to their chemical properties. There are in all nine chapters: the first is introductory; the second deals with the reversibility of reactions between antibodies; the third with the velocity of reaction (homogeneous systems); the fourth with the velocity *of reaction in heterogeneous systems*; the fifth with equilibria in absorption processes; the sixth with the neutralisation of the hæmolytic properties of bases and of lysins of bacterial origin; the seventh with the neutralisation of diphtheria toxin, ricin, saponin, and snake venoms; the eighth with the compound hæmolysins; and the ninth with the precipitins and their antibodies. The fact that we possess a work summarising the achievements which have been gained in the chemistry of immunisation is of the utmost importance to medical science and no one is better fitted to write upon this interesting aspect of the subject than Professor Arrhenius who has done so much to join physics and chemistry together in the elucidation of biological problems.

Tumours of the Cerebellum. By JOHN WYLLIE, M.D. London: H. K. Lewis. 1908. Pp. 109. Price 4*s.*—The author explains in his preface that this work is based on the careful analysis of a large number of recorded cases, all of which "were proved to be cerebellar tumours, either by operation or post-mortem examinations." There is little new to be found in the book but a good summary is given of the knowledge which at present exists in regard to tumours of the cerebellum. Dr. Wyllie also expresses the views which he himself has formed on the subject. Occasionally he finds himself in opposition to the opinions expressed by some of the most distinguished of living neurologists. For instance, he maintains that nystagmus is a very frequent symptom of cerebellar tumours, whilst it is usually held, or at least some authorities state, that although nystagmus is an occasional symptom of tumour in many parts it is not frequent in tumours of the cerebellum. This symptom may not present itself with the frequency of headache, vomiting, optic neuritis, or ataxia, but Dr. Wyllie is of opinion that it is often met with when the cerebellum is the part affected. We have perused this small volume with interest and commend it as a work by a careful observer on a condition which has during recent years attracted much attention.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. I., No. 5. March, 1908.—An interesting paper is contributed to the Epidemiological Section by Mr. R. C. Punnett, M.A., on Mendelism in Relation to Disease, which will repay the attention of those interested in recent advances in the investigation of problems of heredity. In the Medical Section Dr. Samuel West writes on the Acute Suffocative Catarrh of Laennec; in the Surgical Section Mr. A. H. Tubby on Coxa Valga; in the Pathological Section Mr. J. B. Leathes on Acidins in Pregnancy; in the Therapeutical Section Dr. Harry Campbell on the Therapeutics of Diet; in the Obstetrical and Gynæcological Section Dr. Martin Randall with Mr. T. W. P. Lawrence on Ovarian Dermoid with Secondary Cysts connected with the Omentum; in the Electro-Therapeutical Section Dr. H. Lewis Jones on the Principles of Ionic Medication; in the Odontological Section Mr. J. E. Spiller on the Dental Uses of Paraform; and Mr. W. J. Law, on the Termination of Nerves in the Teeth of Mammalians; whilst the Clinical, Dermatological, Laryngological, and Otological Sections are occupied with reports of many cases and specimens.

enacted in one of the ancient public clinics. This tableau, which is upon the body of the vase, displays seven persons, the central figure being the medical attendant, almost a youth. He is seated and engaged in bandaging the arm, just above the wrist, of a man standing before him. Behind the operator, and apparently intended as being attached to the wall of the saloon, or booth, in which the scene is situated, are three objects which M. Pottier considers to be cupping glasses.[2] In front of the surgeon is placed a basin for containing water with which to sponge the wounds. Beyond this and also facing the operator is a second patient seated upon a stool. He has the upper part of his left arm bandaged with a white material tied crossways over the biceps. His left foot is also tied up with a strip of red material. To the form and colour of these M. Pottier thinks some magical as well as medical import was attached. The other personages in the field of the vase are a man standing, of whose malady nothing can be detected beyond the presence of a large bandage across the chest and who is talking to a dwarf with disproportionately large shoulders and short swollen limbs and pointed beard. This diminutive figure is naked and illustrates most accurately the chief physical peculiarities of his type and is, from a medical point of view, the most valuable figure upon the vase. He carries over his shoulder a hare, no doubt indicating that he is the page of the medical officer with whom, as was common in Greek social life, the visitor wished to be on special good terms to insure prompt attention from his master and so had brought a gift. It would appear to have been a happy thought to utilise a dwarf as servant to a medical officer, thus providing him with a patient offering in his person a constant object of study. Beyond the dwarf the sixth person is standing with her left leg bandaged. The seventh figure is also standing but is mutilated and is very indistinct. The first four patients are all supporting themselves with stout sticks as if weak from loss of blood. The conclusion which Dr. Pozzi and M. Pottier arrive at is that the scene upon the vase depicts the bleeding of patients, a remedy frequently used in ancient therapeutics. Hippocrates recommended cupping at the limbs, preferably the arms, though sometimes the feet, and it is upon these that the bandages upon these figures are placed. Moreover, the bandages are not bound as they would be for fractures or recent wounds. One patient, it is true, has a bandage across the chest but Dr. Pozzi cites special cuppings thereupon, or upon the shoulders, as being mentioned by Celsus. This explanation of the tableau would explain the youth of the operator, he being engaged in a simple operation, and the middle age of all the patients. We know that Timarchus as a medical student was employed in his practice by Euthydicus and doubtless the young man shown upon the vase had a more experienced physician or surgeon with him at the municipal clinic. The essay of M. Pottier is furnished with a plate representing the whole scene upon the vase, spread out as a continuous flat picture, also of the new vase painting of the wounded athletes in the Athens museum. The publisher of the "Monuments et Mémoires Fondation Eugène Piot" for the Académie Française is M. Ernest Leroux of Paris.

SECRET REMEDIES AND QUACK MEDICINES IN SWITZERLAND.

SWITZERLAND is an eminently democratic country and has always been in the van against authority other than that derived from the people. Yet it does not go so far as to allow fools to be exploited by mischievous quacks without at least warning them. We learn from the *Feuille D'Avis de Montreux* of April 9th that the health authority of the canton of Vaud has, in response to many inquiries as to the value of secret remedies and "specialities," issued a warning putting the public on its guard against advertisements of nostrums. The notice goes on to say that the more alluring promises of cure are as a rule fallacious. There is no efficacious remedy against drunkenness, no infallible specific for tuberculosis or cancer, and no marvellous panacea for the re-establishment of health. Foreign "*specialistes*" have tried to enter the canton to exploit unfortunate invalids, but a rigorous application of the law has thwarted their projects. It is regrettable that there are no legal regulations similar to those against lotteries, so that the dangerous advertisements might be forbidden. The sanitary authority concludes by saying that it can only advise people never to have recourse to secret remedies the therapeutic effect of which is *nil*, the price of which is exorbitant, and the only effect of which is to delude the sufferer and to prevent him from applying for medical advice which might do him good. We congratulate the canton of Vaud on having so sensible a health authority and wonder when we shall see the London County Council issue a similar warning.

THE ETIOLOGY OF APPENDICITIS: AN EVER-PRESENT QUESTION.

THE cause of the apparently sudden outburst of appendicitis which has occurred within recent years has exercised many minds and the explanations have been numerous. In THE LANCET of April 11th, p. 1115, in "Notes from China," it was suggested that some anatomical peculiarities in the appendix in European races might predispose to appendicitis. An interesting pamphlet has recently appeared at Madras in which this problem has been attacked in a somewhat unusual way, for the writer, Mr. James Harris, L.M. & S., has attempted to explain not the increase of appendicitis in this country and in America but the comparative rarity of the disease in India. It seems to be clear that appendicitis is rare in India. In October, 1907, the editor of *Medical Missions in India*, the journal of the Medical Missionary Association of India, invited replies to the questions, What is your experience of appendicitis among natives of India? If in your experience it is rare, can you suggest a reason? The editor himself mentioned that he had never diagnosed a case of appendicitis in 18 years' practice in India and he suggested the simple diet of the people as the cause of their comparative immunity. 13 replies were received and though some of the writers had had experience of India extending over many years, yet they reported only 11 certain and five doubtful cases of the disease. Only two or three of those who wrote offered any opinion as to the reason for this immunity and these agreed that the main factor was the diet, though it was also suggested that the absence of violent exercises had some influence. One writer quoted with approval Mr. W. H. Battle's explanation that the introduction of steel rollers for the milling of flour has been responsible for the increase in Great Britain and America, as small particles of steel can be found in the flour; and steel-ground flour is almost unknown in India. Mr. Harris will have none of these explanations. He points out that natives in India generally bolt their food, that the grinding stones in India leave many stony particles amongst the material that has been ground, and that many seeds of fruits are swallowed whole. Yet in spite of all these likely causes appendicitis hardly ever occurs. Mr. Harris's explanation is two-fold. The first suggestion is that the habitual purgation which occurs in India prevents the lingering of irritating materials in the cæcum. We may quote the words of the pamphlet: "From the day, nay, even the hour, the Indian gentleman emerges from the fœtal state to infancy to the date of his which the general condition of the patient will justify the prolongation of the operation. Mr. SYMONDS thinks that it is less harmful to leave a ureter which is still supple but when the ureter is much enlarged and rigid the chance of its recovery is much less. Coincident disease of the bladder is a further indication for removal of the ureter either at the same time as the kidney or a little later, for it seems probable that recovery from the vesical tuberculosis is less likely if the discharge of tubercle bacilli from the ureter still continues. Lastly, the question of the possibility of removal of a localised tuberculous mass from a kidney, a partial nephrectomy, had to be considered. In one of Mr. SYMONDS's cases the kidney showed a very localised patch of tubercle, though some miliary tubercles were also present. *It seems probable that at a little earlier* stage a partial nephrectomy might have been possible. The commonest site of early deposit of tubercle in the kidney is the lower pole and when the disease appears to be limited to this position the removal of this portion only seems fully justifiable but we do not yet know whether the tuberculous ureter would recover if the irritation of urine were still present; it is possible since tuberculous affections of the bladder are not necessarily fatal. It is probable that slight cases of tuberculosis of the kidney may recover without operation, for in the lung it is certain that tuberculous nodules may obsolesce; but when the cystoscopic examination shows that the ureteric orifice is characteristically affected it *is certain that* the renal disease is hopeless and the sooner the organ is removed the better.

---

[2] In reference to this subject it should be noted that Dr. C. P. Lambros of Athens in 1895 published a special treatise upon the phlebotomy of the ancients in Greek but presented a French translation of it, which may be found in the Archives de l'Académie de Médecine, to that society.

◆

The Milk Problem.

THE promise of the President of the Local Government Board that, at no distant date, he will introduce a measure for the better regulation and control of the national milk-supply, at once justifies a hope of the near approach of a great sanitary reform and, at the same time, renders it the duty of all who aspire to guide public opinion to pave the way for this reform by the diffusion of information concerning the conditions essential to its accomplishment. An important step in this direction has been taken by Dr. JOHN C. THRESH in a lecture delivered at the University of Birmingham on March 30th under the auspices of the Midland Counties branch of the Incorporated Institute of Hygiene, and we are indebted to the courtesy of the general secretary of the institute for an opportunity of submitting an outline of Dr. THRESH's views to our readers, while regretting that the limitations of space prevent us from publishing them in their entirety. After traversing a good deal of familiar ground, in relation to the usefulness of milk as an article of food both for children and for adults, and also to its qualities as a nutritive medium for bacteria, Dr. THRESH laid down the general principle that the points chiefly requiring attention are the healthiness of cows, the exclusion of dirt, and the maintenance of the milk at a temperature sufficiently low to check bacterial multiplication. In order to secure these essentials he would have all tuberculous cows destroyed under veterinary inspection, with compensation to owners in proper cases; and he would enforce the cleanliness of cowsheds, the purity of all water employed in or about a dairy, the regular grooming of cows, with careful removal of dung from their flanks or udders, the cleanliness of pails, milking-stools, and other utensils, and the cleanliness of the hands and clothes of milkers. The milk drawn under such conditions, unless sold for immediate consumption, should then be cooled to a temperature of 40° F. and protected from adulteration in locked churns, while the railway companies should be called upon to supply sheltered storage for such churns and to convey them in such a manner that the preservation of a low temperature should be secured. For the maintenance of these conditions he would place the inspection of cowsheds and dairies under the local sanitary authorities of every district, rendering it a duty to be done instead of a possibility to be neglected, and would give an appeal to the county or other superior authority in every case in which neglect was imputed. Dr. THRESH's few references to preservatives and his belief in the efficacy of low temperature in checking bacterial growth justify the conclusion that he would entirely prohibit the addition of chemicals, and while he admits that his suggestions would only extend as far as to dealers he appears to think that the proper care of milk in the homes of the purchasers may in time be hoped for as a result of "education." He would, however, require retail milk-sellers to be licensed annually, and would render the renewal of the licences dependent upon the careful observance of such conditions of storage and exposure for sale as might be laid down from time to time by the proper authorities.

It is obvious that the first inquiry of a milk-purveyor, either upon a large or upon a small scale, if the trade were confronted with proposals for legislation of this kind, would be as to its probable effects upon the profits of his business, and from this point of view Dr. THRESH's views are decidedly encouraging. He asserts that his demands are "not only reasonable and practicable and in the interest of the general well-being of the community, but that they will also serve the best interests of the great dairy industry," and he rests this opinion upon his belief that the "amount of milk used at the present time is only a fraction of the amount which should be used, and which will be used when a purer milk is available." He quotes some figures supplied by Dr. G. SOWDEN, the medical officer of health of East Ham, a district with a population of over 100,000 persons, chiefly of the working class. Dr. SOWDEN found that the amount of fresh milk used daily averaged a little less than three ounces per person, or one pint per person per week. The 100,000 persons used 950 dozen tins of condensed whole milk and 1800 dozen tins of condensed separated milk per week. "The total consumption of milk of all kinds is under two pints per person per week, and of this very nearly half is imported milk and over one-fourth is skimmed milk." Dr. THRESH points out that, while nearly half of the milk consumed in towns is of the imported variety, its cost is two or three times that of fresh milk of similar quality; and he argues that if "by gaining the sympathy of the public this sale (of imported milk) could be decreased, it would be of very great advantage to our milk producers and, what is even of greater importance, it would be to the advantage of the poor." There is abundant evidence to show the influence which a wholesome and sufficient milk-supply would be

Hastings, and Tunbridge Wells than elsewhere. Manchester and Glasgow were, as usual, the most sunless localities, but Birmingham and London were not much brighter. In London the total number of hours, 169, was 88 less than last year during the same period, and at Lowestoft the figure was 166 hours less.

MEASUREMENT OF RESPIRATORY MOVEMENTS.

OUR teaching concerning the mechanism of respiration has altered less in the last 50 years than that relating to any other subject embraced by the medical curriculum. To a large extent this apparent lack of progress has been due to the exhaustive and accurate account of the human mechanism of respiration published by Dr. Hutchinson in Todd's "Cyclopædia of Anatomy and Physiology" in 1852. With the introduction of x rays some nine years ago it was expected, and to a very considerable extent the expectation has been justified, that our knowledge of the respiratory movements of the diaphragm, ribs, and thoracic viscera would be revolutionised. As originally used, the x rays were too divergent in character to give accurate information as to the *extent* of these movements; for instance, earlier investigators estimated the total vertical movement of the domes of the diaphragm as varying from 75 millimetres to 90 millimetres (3 to 3½ inches). With more accurate instruments, such as Groedel's orthodiagraph, these movements are found to be much less than originally estimated. Working with this instrument Dr. J. F. Halls Dally[1] finds on examining 100 healthy individuals, varying in age between 15 and 35, that "the absolute range of movement of the diaphragm between deep inspiration and expiration in the adult male is, on the right side 34 mm., on the left side 32 mm. The range in adult females amounts to 27 mm. on the right side and 25 mm. on the left side." In all his measurements of the neck, clavicles, shoulders, and ribs, with the exception of the lateral expansion of the ribs over the left hypochondrium, Dr. Dally finds that the movements of the right side of the thorax exceed those of the left. Dr. Dally was amongst the first to recognise the importance of the "transradiant triangle" of the thorax. This is best seen when the thorax is examined obliquely; it corresponds to the posterior mediastinum of anatomical text-books, being bounded behind by the spinal column, in front by the posterior border of the heart and pericardium, and below by the shadow cast by the domes of the diaphragm and their contents. As an inspiration proceeds this triangle is seen to open up. The widening of the triangle was originally supposed by Keith[2] to be due to the inspiratory forward and downward swing of the heart, b Dr. Dally finds the widening of the triangle is due also to backward movement of the spinal column which takes pla towards the end of a full inspiration. In this movement th curvature of the dorsal region is undone to a certain degre Dr. Dally attaches a high importance to the spinal mov ment as a means of complete expansion of the lungs. I the paper just communicated to the Royal Society D Dally gives merely the average measurements of the respir tory movements. However useful such measurements ma be, only a complete statement of all his measurement with an accurate description of how they were obtained can be of real service to those who are at present investigating this subject.

THE ADMISSION OF WOMEN TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN official circular has been sent out by the Council of the College inviting Fellows and Members to give their opinion "Yes" or "No" on this subject. We are asked to say that an unofficial circular is about to be issued to Members regarding the admission of women to the *Membership* and *Fellowship*, and that in this circular it is suggested that Members should disregard the request of the Council of the College that the answers to the questions in the official circular should be in the form of simply "Yes" or "No." The authorities of the College hope that Members, with a view to avoiding confusion as regards the result of the poll, will record their answers on the official *balloting-card* in accordance with the instructions for voting contained thereon.

COST OF MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE East Sussex education committee on April 7th adopted the report of the special subcommittee appointed to draw up a scheme for the medical inspection of children. *When the subject first came* before the education committee a prophecy was made that the carrying out of the provisions *of the Act* would necessitate an expenditure of at least £500 a year, there being nearly 26,000 children in 176 schools in the committee's jurisdiction. *Proceeding on the most economical* lines, the subcommittee finds that the cost of the working *of the Act* will be £800 a year. The initial cost *for the first year* amounts to £1371 16s., the difference between this sum and £800 being the estimated cost of the appliances. *It has been decided to* appoint a superintending medical officer whose whole time shall be into "incurable" wards, or failing this that they should be discharged as at present, the committee being of opinion that advanced cases of this kind are less of a public danger than those who are less ill and therefore able to go about, a view which is hardly likely to appeal to those who advocate the segregation of advanced cases. In regard to the cost of its proposal the committee states that the average number of soldiers invalided annually for tuberculosis of the lungs is about 400, and it estimates that, excluding the advanced cases and those who refused to remain in sanatoriums, the number remaining for treatment would not exceed 350. The committee suggests that in order to allow of sufficient accommodation 200 beds should be retained, each being able to accommodate two patients a year. It is thought that the cost of maintaining a bed will average about 30*s*. a week and the scheme would thus entail an expenditure of £15,600 per annum. The committee therefore estimates that the total cost of the scheme will not exceed £20,000 per annum and that a part of this will be counterbalanced by the fact that tuberculous patients will remain in military hospitals for a shorter time than at present. It is suggested that at first the Army Council might make a reasonable contribution towards the extension of a sanatorium which proposed to increase its accommodation, such contribution, however, to be met by a corresponding reduction from the annual cost as estimated above.

---

[1] Proceedings of the Royal Society, Feb. 6th, 1908.

[2] THE LANCET, March 7th, 1903, p. 633.

The proposal to make some effective provision for the treatment of the tuberculous soldier is one with which we are in full sympathy. At present, after discharge from the army the unfortunate sufferer from pulmonary tuberculosis has either to seek admission to one or another of the civil charitable or paying institutions, with the chance that by the time he is admitted his disease is too far advanced to render him suitable for sanatorium treatment, or else to remain at home endeavouring to earn enough to support himself, in which he is handicapped by his lack of experience of civilian occupations. The scheme suggested by the committee, though obviously not perfect, is a serious attempt to deal with a difficult problem. The proposals are admittedly tentative and are doubtless capable of modification in detail if the general principle is accepted by the Army Council, for the committee states in its report that if it is so accepted it will proceed to elaborate it in detail. It seems to us that there are some few matters in connexion with the report which require careful consideration. The first is that the practical withdrawal from the civilian population of even 200 sanatorium beds is a serious limitation of the already scanty accommodation available for those of the poorer classes of the community affected with pulmonary tuberculosis, and in our opinion it ought clearly to be emphasised that a sufficiency of new beds should be established to avoid any such detraction from the resources provided for the civilian sufferers. It may be doubted whether, given the provision of means for treatment, the yearly number of cases will prove to remain at the low figure of 400, especially if very early and suspicious cases are at once drafted to sanatoriums, since there will be less likelihood of concealment of the disease on the part of the sufferers. The results achieved by sanatorium treatment under the proposed conditions should be very satisfactory, as the cases for the most part will be early cases in previously healthy adults, and a short period of observation in a military hospital should be of value in the proper selection of cases for sanatorium treatment. One defective feature of the scheme is the proposal in regard to advanced cases, for which more adequate provision is necessary if the army is going to assume responsibility for the tuberculous soldier. In civil life, apart from the Poor-law infirmaries and a few "incurable" wards or homes, little provision exists for treatment in institutions of advanced cases, and if the army is going to evade its responsibilities in regard to this section of its patients little advance has been made and it must not be forgotten that the failures from the sanatoriums will serve to swell the numbers of these "advanced" cases which, the view of the committee notwithstanding, are not the least dangerous from the point of view of infectivity.

Annotations.

"Ne quid nimis."

A GREEK MUNICIPAL HOSPITAL IN THE FIFTH CENTURY B.C.

IN THE LANCET of Jan. 12th, 1907, p. 104, a drawing was given, in illustration of "The Medical Art in the Homeric Period," of a scene depicted upon a Greek vase of Achilles binding up the wound of Patroclus. Since those notes were published M. E. Pottier has edited in the "Monuments and Memoirs" of the Paris Academy, funds for which were provided by the late M. Piot, a still more interesting, from the medical point of view, piece of ancient ceramics under the title of "Une Clinique Grecque au V^e Siècle." Several other delineations of the first aid applied to wounded warriors have previously been noted and some published—notably, the amphora in the Hope collection showing Sthenelos binding up the hand of Diomedes; a vase in the museum at Florence depicting soldiers binding each other's wounds; an Etruscan mirror at Bologna, showing Machaon, the primitive surgeon, performing the same office for Philoctetes; and a seated warrior having his limb dressed by a surgeon, engraved upon a seal given in the "Dictionary of Antiquities" of M. Saglio. There are also some figures of wounded legionaries having their limbs bandaged upon the Roman column of Trajan.[1] It will be noted that all these instances are connected with injuries received in warfare, while the new vase, for a reproduction of which we are indebted to M. Pottier, depicts a scene in a hospital, or clinic, of some city, probably Athens, in times of peace, and so is unique. We know from the classics, but more particularly from inscriptions, that the Hellenic cities used to have public places supported by the citizens where physicians and surgeons, provided with the necessary appurtenances, attended to the medical needs of the poorer members of the community. The cost of such arrangement, including the payment of the operators, was defrayed by a special impost. The *ἰατρικόν*, and the post or edifice placed at the disposal of the surgeons was termed an *ἰατρεῖον*. This physicians' tax is often mentioned in Græco-Egyptian papyri but there was devoted to paying salaries to the civic medical officers who had to take part in post-mortem examinations, to combat epidemics, and to give certificates of births and deaths. M. Pottier, fortified by the advice of Dr. Pozzi who, he tells us, in addition to his qualities as a practitioner, possesses the ardour of an antiquary, is quite certain that the scene depicted upon the new vase is to be considered as being cutting off the nose and ears. They were skilful in performing Cæsarean section and other abdominal operations, and are said to have practised inoculation against small-pox and to have discovered the art of cataract couching. The surgeon was recommended to acquire manual dexterity by cutting flowers, the hollow stems of plants and bladders filled with paste, and by putting sutures on skins. Health was thought to be promoted by the exhibition of an emetic once a fortnight, a purgative once a month, and blood-letting once a year. Among the causes of disease Karma, or Fate, was thought to take a prominent place. The murderer of a Brahmin was said to suffer from anæmia and a cow-killer from leprosy, thus assigning a physical cause for moral delinquency. In diagnosing disease palpation, percussion, and auscultation were recognised. In the palmy days of Buddhism in India, during the reign of Asoka in the third century, hospitals were erected and a regular system of medical administration was established throughout the country. With the decline of Buddhism these institutions disappeared. The contempt of the Mahomedan conquerors of Hindustan for the scientific knowledge of the Hindus and the diffusion of the European system of medicine contributed to a decline of Hindu medicine and surgery. The Sanscrit works became more inaccessible; imperfect copies were substituted, so that confidence was diminished, while superstition and quackery increased. Turning to the present condition of Hindu medicine Dr. Kugler describes native physicians in uncomplimentary terms. In a large majority of cases they are said to kill the patient by over-drugging or by poisoning with aconite, arsenic, or mercury. The excessive use of mercury accounts for the commonness of cases of ankylosis of the jaw, necrosis of the maxillary bones, and gangrene of the cheek. The native "doctors" frequently take advantage of the superstitions of the people who attribute many forms of nervous and mental diseases to devils. Hence the exorcising of devils and other methods of witchcraft are still practised. To-day there are comparatively few Hindu practitioners who endeavour to combine the modern European system with the teachings of the Ayur Veda. The majority practise hypocrisy and deception. Dr. Kugler hopes that as the years go by more attention will be paid to Ayur Veda medicine by all Indian students of medicine, so that what is good in it may be incorporated into a new system which, belonging neither to the East nor to the West, may be a universal system of medicine having for its object only the amelioration of human suffering and the prevention of disease.

---

[1] There is also a vase now at Athens representing wounded athletes to which we propose to refer on another occasion.

INFANTILE AND JUVENILE TABES.

IN an interesting paper published in the *Wiener Medizinische Wochenschrift* of March 21st Dr. Otto Marburg discusses the general characters of infantile and juvenile tabes and records a case in a girl aged two years. The patient was the fifth child of a man who had contracted syphilis 20 years before. The child was born healthy and developed in a normal manner until after the age of one year, when it was noticed that she did not see as well as before. Ophthalmoscopic examination at the time revealed the existence of atrophy of the optic nerve. It was also found that the child could no longer lift herself up or keep her head up, and that although the arms and legs could be moved she could not walk. Shortly afterwards she developed peculiar attacks of dyspnœa with crowing inspiration and marked cyanosis. She was admitted to hospital under Professor Escherich. On examination the child was noticed to be pale, fairly nourished, and of normal development. She lay quietly on her back and was quite unable to speak; she heard sounds, laughed from time to time, and took her food naturally. The pupils were of less than medium size, the left being larger than the right, and the reaction to light was sluggish. There was no disturbance of the sensibility to pain. The power of the movements of the limbs was apparently not disturbed but the muscles of the back and of the neck were weak, so that the child could not sit upright or hold her head erect. The muscles were in general hypotonic and the tendon reflexes were absent. From time to time attacks of laryngeal spasm developed. Electrical examination did not afford any evidence of tetany and the characteristic macular changes found in the Tay-Sachs form of amaurotic family idiocy were wanting. The case was therefore regarded as one of infantile tabes following on congenital syphilis. Dr. Marburg, who in 1903[1] was able to collect 34 cases from the literature, now gives references to 17 additional cases and discusses the general features of the condition as recorded in the total of 51 cases which he has thus collected. In 34 of these there was a history of congenital syphilis, while in four syphilis had been acquired; in the remainder either no details were given or there was no evidence of infection. In only 12 of the cases was there a history of tabes or paralysis in the parents. One very striking example is of special interest: a tabetic mother had a family of three, of whom the eldest son suffered from juvenile tabes, the second son from paralysis, and the daughter from cerebral syphilis. In the 50 cases in which the sex was stated 29 were girls and 21 were boys—a striking contrast to the sex incidence in adults. The greater the number of cases studied the more the general similarity of the symptoms to those of adults becomes apparent. Disturbances of sensation were observed in 64 per cent., Argyll Robertson pupils in 74 per cent., and loss of reflexes in 86 per cent.—figures which are strikingly similar to those in adults. An exception, however, must be made in regard to ataxy and Romberg's sign which were present only in 56 per cent. and then not in any great degree. It is possible, according to Dr. Marburg, that this peculiarity may be due to the relatively mild course of infantile tabes. Optic atrophy, on the other hand, occurred in 44 per cent. of the cases, which is more than double the frequency of that condition in tabes in adults. Disturbances of micturition occurred in 48 per cent. of the cases and in some these appeared to be the initial symptom. Dr. Marburg lays stress on the importance of congenital syphilis as the basis of severe organic affections of the nervous system and on the necessity for careful observation of unusual nervous manifestations in children of syphilitic inheritance.

THE EARLY HISTORY OF THE HOME DEFENCE MOVEMENT.

AT the moment when the old order is giving place to the new in regard to the military forces for home defence it may be interesting to recall the fact that the Volunteer movement of 1852 owed its origin in no small degree to the active interest of the late Sir John Charles Bucknill, M.D., the alienist, whose name, coupled with that of Dr. Hack Tuke, are household words in the early history of scientific psychology. In the year 1852 a meeting was convened at Exeter, presided over by Lord Fortescue, to consider the necessity for the enrolment of a corps of citizen soldiers, especially with relation to coast defence. It was pointed out at that meeting that the last successful invasion of England—namely, that by William of Orange—was achieved by the landing of an army on the South Devon coast. Dr. Bucknill was the active spirit in this agitation and a motion was carried unanimously in favour of memorialising the War Office asking for permission to raise a force to be known as the Exeter and South Devon Volunteers. The required powers having been obtained, Dr.

ral dissolution he is subjected to the cruel act of purgation. urgative for everything and to everyone. The suckling abe, the hardy adult, and the decrepit old, everyone eceives a purge for any distemper, imaginary or real." he second factor in the prevention of appendicitis is, n Mr. Harris's opinion, the attitude adopted in defæcation y natives of India, and he has illustrated this by reproductions of two photographs. These show that the native athers up the fringes of his cloth into a ball and presses hem on the ilio-hypogastric region. He then squats down, he right foot pressed firmly on the ground and the right high pressing firmly on the right ilio-hypogastric region. he left foot is placed behind, resting on the toes, so that he left thigh forms a large angle with the left abdominal all. In this attitude *the cæcum is well compressed, the* egurgitation of fæces or gas from the lower bowels is prevented, and a stimulus to downward peristalsis is kept up; hus the cæcum is thoroughly emptied and the contents are riven lower. Then the native changes so that the position f the lower limbs is reversed, the left thigh being sharply exed and the right thigh extended; in this way the lower owel is emptied. Thus Mr. Harris maintains that frequent urgatives and the rational posture adopted by the Indian in he act of evacuation are the two main causes *that help to* he rarity of appendicitis among the Indians. We are nclined *to think that both of the* facts mentioned really ave an influence in preventing appendicitis. Constipaion certainly has a tendency to block the opening of the ppendix or to force fæcal materials into it. Therefore a egular emptying of the cæcum must tend to diminish he probability of appendicitis. The phraseology adopted is ccasionally rather peculiar. For instance, in objecting to the suggestion that the use of steel rollers in *grinding flour* is a cause of appendicitis in England, the writer says, "If there could be any lien *on such* a bleb of a cause, I can point out much more formidable ones in India." In speaking of the presence of particles of stone in the meal he says: "Leaving aside the direct pathological consequences the chances of swallowing small stones which the unskilled cook fails to remove from the rice are very great. A slow eater and a careful masticator when confronted with them after exhausting his ire on the household, might remove or spit out the offender and continue his meal when alone. In an assembly or in a public feast to put *one's finger* into the mouth to remove the stone or spit it out is a pollution and is indicative of low birth. In preference to this stigma one would easily wash in any number of them with impunity."

PROLONGED CONJUNCTIVITIS FOLLOWING CALMETTE'S OPHTHALMO-REACTION.

EVIDENCE is beginning to accumulate that the ophthalmoreaction of M. Calmette, which is most valuable and has attained world-wide popularity in such a short time, is not quite so innocuous as he has claimed. In THE LANCET of March 7th (p. 716) Dr. A. Maitland Ramsay has reported a case in which a violent reaction accompanied by ulceration of the cornea occurred and a considerable opacity, seriously impairing vision, remained. In the *Boston Medical and Surgical Journal* of March 12th Dr. Malcolm Mackay has recorded the following case. A woman came under observation on Nov. 23rd, 1907, complaining of "rheumatism" of the left knee. For one and a half years she had been troubled with a good deal of pain upon walking, although active and passive movements while sitting down were practically painless. At night she was often kept awake by aching in the joint and at times was awakened by the pain. Examination showed moderate diffuse swelling in and about the joint which was held slightly flexed but could be straightened. There was no redness or heat and the patella was not floating, although lateral movements produced a soft crepitus. There was marked tenderness over the head of the tibia at the external tuberosity about three-quarters of an inch below the articular surface. A cough had existed more or less for two years and there was a family history of tuberculosis. Examination revealed a "pulmonary lesion" and evidence of old spinal disease at the lower dorsal and upper lumbar region. A few tubercle bacilli were found in the sputum. As the patient wished the diagnosis of tuberculosis to be confirmed by an expert she was sent to one, and on Dec. 14th one drop of Calmette's 1 per cent. solution was placed in the right eye. The reaction promptly appeared and was very marked: photophobia, *lacrymation, and gumming of the eyelids* were very troublesome. A lotion of boric acid was used and the condition remained about the same for ten days and then subsided. On Jan. 20th there was recrudescence; the conjunctiva was red and the eye was partly closed. On the 25th the inflammation was severe, the bulbar and palpebral conjunctiva being involved with chemosis and gumming of the lids. Boric acid and zinc drops were prescribed and a boric acid ointment was applied to the lids which developed a row of small pustules. On Feb. 26th, more than ten weeks after the instillation, the conjunctiva was red and there was slight photophobia with some narrowing of the palpebral fissure. The conjunctivitis was confined to the eye into which the tuberculin was put. The patient had never previously had any trouble with her eyes.

THE WEATHER: DEC. 1st, 1907, TO MARCH 31st, 1908.

THE appended figures represent the chief meteorological elements from Dec. 1st, 1907, to March 31st, 1908, in various parts of the kingdom, some of the stations being well-known seaside resorts, others inland resorts, and others again some of the chief centres of population. Compared with the corresponding figures for the same localities published in THE LANCET a year ago the temperature and rainfall show an increase, while the number of hours of sunshine, owing to a much less sunny March, was considerably less. Compared with the average, however, the divergence of temperature was slight, as was also that of rainfall and sunshine for a great many of the stations, but several places in the south-west were a good deal drier than usual and some in the north and north-east appreciably wetter. The mean daily temperature ranged from 50° F. at the Scilly Isles and 49° or 48° at some other resorts in the south-west and at Sandown, Isle of Wight, to 44° at Tunbridge Wells, Blackpool, Glasgow, and Aberdeen, and 43° at Harrogate, while the mean cold of the nights varied from 44° at Scilly and 41° at Falmouth to 33° at Nottingham and Harrogate. Over the country generally the mean diurnal range was small, less than during the same period last year, the highest figure, 12° at Nottingham, being just twice as large as the lowest, 6° at Scilly. The difference in the mean warmth between Harrogate, the coldest place represented in the table, and Falmouth, the warmest place *on* the mainland, was 6·8°, while between Harrogate and Scilly the difference was just 9°. Sandown, Isle of Wight, was a trifle cooler than Torquay at night, but warmer than Bournemouth and Hastings both during the night and day. It will be observed that at Scarborough the mean temperature figures were almost identical with those in London and that both Dublin and Douglas, Isle of Man, were milder than Hastings and the south-east coast of England, while Blackpool had practically the same temperature as Aberdeen. Folkestone, Hastings, and Lowestoft had the least rain, and Falmouth, Glasgow, and Douglas, Isle of Man, the most, while the sunshine was more prevalent at Sandown, Isle of Wight, Jersey, provides a penalty for anyone not qualified as above who "takes or uses the title of veterinary surgeon or veterinary practitioner, or any name, title, addition, or description stating that he is a veterinary surgeon or a practitioner of veterinary surgery or of any branch thereof or is specially qualified to practise the same." The Kingston magistrates, who stated a case for the consideration of the Divisional Court, were of the opinion that the inscription used by the defendant could not be said to "state" that he was "specially qualified" to practise a branch of veterinary surgery but the Divisional Court, presided over by Lord Alverstone, has now held otherwise and the case has been remitted to the magistrates in order that they may convict. It was a point of some difficulty in the opinion of the Divisional Court, and although the Lord Chief Justice was strongly of the opinion that the magistrates had decided wrongly Mr. Justice Darling and Mr. Justice Ridley, who sat with him to hear the appeal, felt grave doubts and were by no means ready to follow him. Lord Alverstone was of opinion that the legislature meant that a person is not to indicate that he is specially qualified to treat diseases of dogs unless he has the necessary qualification, and he went so far as to say that in his opinion the Veterinary Act was intended to stop the treatment of domesticated animals in return for fees by persons who are not qualified unless they tell the public so. A point for the defence which required consideration lay in the wording of the section quoted which forbids the person using the inscription to "state" that he is specially qualified. The preceding section, intended to prevent false representations that a person is a Fellow or Member of the Royal College of Veterinary Surgeons, imposes a penalty for "stating or implying" by means of any title or description added to a personal name that its owner is such a Fellow or Member. The omission of the word "implying" in the 17th Section was dwelt upon on behalf of the defendant as being intentional and as demanding that the statement of special qualification should be definite and not merely made by implication. However, the Divisional Court has given a decision which should not merely protect the Royal College of Veterinary Surgeons against the invasion of its privileges but should also have considerable effect in protecting dumb animals against unnecessary suffering at the hands of unqualified persons, for the practice of the unqualified must always depend to a large extent upon his power to advertise his alleged skill. The case has considerable interest for members of the medical profession in that it calls attention to the weakness of the protection afforded to them by their own Act of 1858, as compared with that granted in 1881 to veterinary surgeons. The medical man and the human beings who are his patients are only protected against the quack who uses titles or descriptions implying that he is registered according to the law and not against one who states that he is qualified in such terms as those used by the defendant at Kingston. But apparently Mr. Justice Ridley would not approve of any further effort to protect the medical profession and the public, for he is reported in the *Daily Mail* to have said that "there was many a quack who was as good as a doctor."

A Herbalist Sued Unsuccessfully by the Society of Apothecaries.

At the Edmonton county court recently an action was brought by the Society of Apothecaries to recover a penalty of £20 from W. T. Gregory, a herbalist at Old Charlton, for attending, advising, and supplying medicine as an apothecary to a Billingsgate fish salesman who had died while being treated by him. The deceased had contracted blood poisoning through pricking his finger in handling skate, and after being attended by a medical man called in the defendant, who at one time was a fish salesman. Gregory undertook to cure him and applied plasters compounded with resin, turpentine, marsh-mallows, elderberries, and parsley. The defence was raised that the treatment thus accorded was surgical and not that of an apothecary, and his honour, Judge Tindal Atkinson, accepted this view of the matter, being of opinion that the case was surgical because the injury was sustained through an external cause, and because he thought that the defendant had acted as a surgeon in the treatment of what, he said, might be called a "minor surgical case." He accordingly gave judgment for the defendant, holding that he was not liable to pay the penalty claimed by the Society of Apothecaries. The case, like that of the "canine specialist" referred to above, shows the difficulty which such bodies as the Society of Apothecaries labour under in the effort to protect the public and their own members, difficulties which arise to some extent out of the use of loose and general expressions in Acts of Parliament. The decision arrived at seems to imply that acts which no surgeon would perform are surgical acts, and although the case no doubt required surgical treatment it cannot be said to have received it. The treatment afforded was, of course, not that which any "apothecary" of the present day would supply, but was at least as near akin to the treatment which an apothecary might be deemed likely to use as it was to that of a surgeon.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 17th, 1830.

MEDICAL CORONERS—CASE OF JAMES BUTLER.

To the Editor of The Lancet.

Sir,—The interest and advantage with which I have perused the excellent observations contained in your Journal, on the subject of non-medical coroners, induce me to submit to your notice some observations on a recent melancholy case, in which the life of an unhappy individual might have been saved, had there been in the country any public functionary whose peculiar duty was the investigation of such branches of jurisprudence as are connected with scientific knowledge.

The case to which I refer is that of James Butler, executed July 27, 1829, for firing the floor-cloth manufactory of Messrs. Downing at Chelsea, under very strong presumptive evidence as to his guilt, contradicted indeed by his strongest protestations of innocence to the last. When I first perused the details of his trial in the month of October last, I felt no difficulty in assigning as the probable cause of the conflagration for which he suffered, the spontaneous ignition of some of the material used in the process of the oil-cloth manufacture. Linseed-oil, lamp-black, and tow (substances largely used in the manufacture), are, under peculiar circumstances of juxta-position, very favourable to this phenomenon, as may also be considered the scrapings of the floor-cloth, often permitted to accumulate in considerable heaps upon the floor.

Such an opinion, if stated at the time of the trial, and supported by the various cases in which combustion has been known to arise spontaneously, and produce many lamentable conflagrations, could not, I consider, fail to have excited the attention of the judge and jury on the occasion; and although they might not by them have been deemed sufficient ground for another trial, would yet have arrested their decision, and excited an additional inquiry. This opinion I some time since stated in a letter to the editor of a morning paper, which was the cause of my introduction to a benevolent individual who had commenced an investigation into the case, and who has since, by rebutting every part of the moral evidence produced against Butler at his trial, succeeded in establishing the fact of his innocence beyond a doubt, and convinced me of the correctness of my opinion, as to the accidental origin of the conflagration.

I do not consider that, from the nature of the evidence before the jury, their verdict can, in any way, be impugned; a mystery hung over the case, which could only be removed by referring the calamity to a cause, of the existence of which they were unacquainted; but it is a melancholy instance of a case in which an irreparable injury has been inflicted upon an individual and his family, because no competent authority existed to intercept the necessary uncompromising denouncement of our penal code. As such, deeming that public justice requires that publicity should be given to the case, I beg to submit my observations to the readers of your invaluable Journal.

I am, Sir,
Your obedient servant,
A. Booth, Operative Chemist.

20, Church-street, Shoreditch,
April 3.

Mr. Booth's talents as a chemist, and the importance of the subject on which he writes, are sufficient to claim immediate insertion for his letter. It is right, however, to add, that we have but a slight acquaintance with the facts to which the writer adverts.—Ed. L.

devoted to the duties, the salary to be £400 per annum, with an allowance of £40 per annum for travelling expenses; also a male assistant medical officer at a salary of £250 per annum, with an allowance of £40 per annum for travelling expenses. The clerical work is to be carried out in the office of the secretary of the education committee. How the total of £1371 16*s.* is made up is shown by the following:—

	£	*s.*	*d.*
Officers' salaries and expenses	730	0	0
176 weighing machines, at £1 5*s.*	220	0	0
176 height measuring standards, at 3*s.* 6*d.*	30	16	0
360 copies of Snellen's test type (two patterns), at 10*s.* per dozen	15	0	0
176 screens, at 10*s.* each	88	0	0
15,000 cards, at 20*s.* per 1000	15	0	0
240 card cabinets (tin)	90	0	0
352 registers	50	0	0
15,000 notices to parents	7	10	0
Five medical officers' note-books, at 2*s.*	0	10	0
Sundries	125	0	0
	£1371	16	0

BACILLARY DYSENTERY.

WE have received a copy of a pamphlet on Bacillary Dysentery written by Dr. A. E. Taylor as a thesis for the degree of M.D. Cambridge. It is based upon an analytical study of 325 cases observed at Outtrim, South Gippsland, Australia, between August, 1902, and April, 1907. Dr. Taylor held the post of surgeon to the Outtrim and Jumbunna collieries, but in addition treated practically all the cases of illness in the inhabitants of the surrounding district, so that his observations are of special interest as a record of the general health of the population of the district, which comprised about 4000 persons. He gives a list of some of the more important conditions observed which include, in addition to the cases of dysentery, 116 cases of diarrhœa, 193 of infantile diarrhœa, 27 of enteric fever, and 19 of appendicitis. He is of opinion that defective sanitation is the chief factor concerned in the propagation of bacillary dysentery and, as an example, its rapid spread among the colliers is attributed to the fact that until recently there were no sanitary conveniences in the coal-pits and the pit water therefore became infected. The disease was most prevalent in the autumn months, chill and exhaustion being very potent predisposing causes. There was a slight preponderance of the cases among males, which is attributed to the greater frequency of exposure to infection and of predisposing debilitating conditions. The evacuations were examined microscopically and bacteriologically in a large number of cases and in no instance were amœbæ found, but invariably a motile bacillus was present the characters of which were in the main identical with those of the Shiga bacillus as given by Kitasato, save that it was more actively motile and was non-pathogenic to dogs. Dr. Taylor, referring to the work of Ohno,[1] who found when working in Manila that there are 15 varieties of the dysentery bacillus all shading into one another but distinguishable by fermentative, agglutinative, and other bacteriological tests, suggests that the bacillus varies in character in different parts of the world. He further believes that some degree of immunity to the disease is not uncommon; on the other hand, he states that one attack so far from leading to immunity seriously predisposes towards subsequent attacks. The duration of the incubation period in his cases usually varied from two days to a week and was most often three days; in one case, however, it was apparently as long as 20 days. Five of the cases were fatal but in only one of these was a necropsy allowed and in this one there was extensive ulceration of the mucous membrane of the whole of the large intestine. Rectal examination by means of a speculum was made in a few of the cases, revealing extensive ulceration in some of them, while in others nothing was seen except scattered areas of inflammation without ulceration. Three types were observed clinically—mild, ordinary, and severe. The onset was usually sudden and associated with severe pain and great prostration. The motions were at first those of foul diarrhœa, soon changing to mucus, pure or blood-stained. Blood appeared in them in 150 of the cases, slough-like membranes in 17, and pus in 21. Tenesmus of more or less severity occurred in 271 and vomiting in 163. The urine was usually dark in colour, of high specific gravity, but free from albumin, sugar, or casts. In three cases, however, a definite cystitis was present. On examination of the abdomen there was usually tenderness at some spots over the large bowel, varying in individual cases, and shown in a diagram appended to the pamphlet with their relative frequency. Relapses and second attacks were found to be very common. The cases lasted from two days to a week as a rule but exceptional cases extended to a period of several months. In regard to treatment, Dr. Taylor states that the mild variety requires at most a slight purge. For the ordinary and the severe cases he commenced treatment by giving a purge; for this purpose he recommends calomel in preference to castor-oil or sulphate of magnesium. If abdominal pain were severe a hypodermic injection of morphine was given at once but if possible hot fomentations with or without laudanum were used in preference. In the majority of cases this treatment proved effective but when it was inadequate rectal injections of boric acid, one drachm to the pint, were given. At first these caused pain and were rapidly rejected but they soon gave relief if they were persevered with and repeated every three hours. If this treatment failed an injection of silver nitrate (ten grains to the pint of water) was given three times daily. Dr. Taylor is to be congratulated on the use that he made of his opportunities for studying the disease and on the interesting record which he has made of his cases.

ANCIENT AND MODERN HINDU MEDICINE.

IN the March number of the *American Journal of Pharmacy* Dr. Anna S. Kugler deals in an interesting manner with ancient and modern Hindu medicine. The Hindus claim that the antiquity of their medical science exceeds that of any other people. It is comprised in the Ayur Veda, or "Science of Life," a work divided into 100 sections, each containing 1000 stanzas. Brahma communicated the Ayur Veda to Dakshprajapati who in turn passed it on to the Ashoini Kumars, the twin sons of the Sun. The oldest extant treatise on Indian medicine is that ascribed to a son of the Vedic saint Atreya, and hence called the Atreya Samhita. When asked questions by one of his pupils on the origin and treatment of disease, Atreya explained that the Ayur Veda could not be fully explained within the limits of human life and that his pupils would have to be content with his own composition which was completed within 1500 stanzas. The two most frequently quoted ancient medical writers among the Hindus are Charaka and Susruta, who dealt respectively with medicine and surgery. Charaka gave a list of 600 drugs which cause vomiting and purging, and described how remedies should be introduced into the body by means of enema syringes. No less than 125 surgical instruments are described in ancient Hindu works but the ancients are said to have understood so well the properties of drugs that surgical methods were seldom resorted to. Thus, abscesses were treated by plasters or poultices and urinary calculi by antilithics and diuretics. The Hindus were expert in plastic surgery, their operations including the transplanting of sensitive skin flaps and the forming of new ears and noses. Their skill in this direction was due to the punishment then so common in India of

* Including membranous croup.

Bucknill was enrolled as the first recruit in the first regiment of Volunteers established on the new system in the United Kingdom. The corps was officially named the 1st Exeter and Devonshire Rifle Volunteers and proved the nucleus of the system which has now given place to the Territorial Force. His services in connexion with the movement were recognised by the erection by public subscription of a memorial embellished with a medallion portrait of the distinguished alienist in Northernhay, near Exeter Castle. It was unveiled by H.R.H. the Duke of Cambridge in 1895.

THE Ingleby lectures in connexion with the Faculty of Medicine of the University of Birmingham will be delivered on Thursdays, May 7th and 14th, at 4 o'clock, in the Medical Lecture Theatre of the University, by Mr. Christopher Martin, surgeon to the Birmingham and Midland Hospital for Women, who has taken for his subject Myoma of the Uterus.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary Comitia was held on April 13th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

A communication was received from the secretary of the Burlington Fine Arts Club requesting the loan for exhibition of an illuminated manuscript Psalter in the possession of the College. The request was acceded to.

The PRESIDENT then delivered his annual address, in the course of which he referred to the Royal honours that had been conferred on Fellows, and also mentioned the medals and scholarships which had been given by the College during the year. The Harveian oration and the lectures delivered during the year were then mentioned and the gifts presented to the College were again acknowledged. A brief review was also given of the principal events which had occurred in relation to the affairs of the College. The President then read obituary notices of those Fellows who had died during the year: Dr. W. H. Ransom, F.R.S., Dr. E. Markham Skerritt, Dr. Robert Barnes, Surgeon-General Sir Joseph Fayrer, Bart., Dr. Julius Dreschfeld, Sir W. H. Broadbent, Bart., Dr. G. F. Elliott, Dr. H. Montague Murray, Sir Alfred B. Garrod, Dr. F. Willcocks, and Dr. Oswald A. Browne. The President then expressed his thanks to all the officers of the College for their services during the past year and acknowledged the courtesy which he had always received from the Fellows.

Dr. J. E. POLLOCK proposed a vote of thanks to Sir R. Douglas Powell for his address and for the services which he had rendered to the College during his year of office. This was seconded by Dr. NORMAN MOORE and carried unanimously.

The REGISTRAR (Dr. E. LIVEING) read the by-laws regulating the election of President. A ballot for President then took place, when Sir R. Douglas Powell was re-elected by a large majority.

The SENIOR CENSOR (Dr. D. FERRIER) delivered to Sir R. Douglas Powell the insignia of the office of President, and the PRESIDENT gave his faith to the College. He expressed his thanks to the Fellows for having re-elected him.

The PRESIDENT then dissolved the Comitia.

MEDICINE AND THE LAW.

The Legal Liability of the Anæsthetist.

THE legal aspects of the anæsthetist's position when death occurs during anæsthesia produced with a view to the performance of a surgical operation were discussed at some length by Mr. R. Henslowe Wellington in his paper on the subject read before the Medico-Legal Society and reported in THE LANCET of April 4th, p. 1003. In conclusion, the learned coroner summed up his views by saying that the administration of any anæsthetic, whether for a local or a general anæsthesia, by unqualified practitioners, which was carried on to a very large extent throughout the kingdom, was a grave public danger and should, perhaps, be made a penal offence by statute. He had before dealt with the present position of the person administering the anæsthetic in cases in which death has followed its use and had defined the circumstances rendering him criminally liable by a quotation from Archbold's "Criminal Pleadings," where the editor says that "It seems that if a person, whether he be a regular practitioner or not, honestly and *bonâ-fide* perform an operation, or use a dangerous instrument, which causes the patient's death, he is not guilty of manslaughter; but if he be guilty of criminal misconduct arising from gross ignorance or criminal inattention, and not from a mere error of judgment then he will be guilty of manslaughter." Mr. Henslowe Wellington, although he made reference to the anæsthetist's liability to a civil action for damages, had before him mainly throughout his paper the question of a possible liability to prosecution upon a charge of manslaughter, rather than the risk of being sued under Lord Campbell's Act for civil damages. This, however, is a very real risk, and whether he deserves it or not an anæsthetist may be asked to pay damages by a widow in respect of the loss of her husband, and he may have a verdict found against him by a jury upon the civil question, although he has not been prosecuted for manslaughter and could not have been so prosecuted with any likelihood of conviction. The question of fact whether he has been guilty of negligence is one which a jury decides after the law has been explained by the judge, and a jury which might hesitate to send a fellow man to prison might desire that he should compensate a widow with an orphaned family for the result of an act which, to use general terms, he ought not to have done, or ought to have done better. Juries are composed of men with human sympathies and are not too always closely bound by legal definitions. The person without a medical qualification who administers an anæsthetic naturally and rightly runs more risk of an adverse verdict than the medical practitioner who does the same without having specially qualified himself to do so. Neither, however, can in any conceivable circumstances claim that he did not know that what he was doing involved possible danger to human life and each must be held to be aware to some extent of his own limitations. Without going into the question raised by Mr. Henslowe Wellington as to whether dentists qualified as such only should administer anything beyond nitrous oxide, it may be pointed out that anyone registered as a medical man or as a dentist who administers an anæsthetic has to consider that should a fatality occur it is quite possible that it will be suggested that he is liable for it criminally or, still more probably, civilly, and that he may then have the case put against him thus: that he undertook to do that which his training and experience did not qualify him to carry out successfully except in favourable circumstances; that at the same time his training and experience qualified him to know that unfavourable circumstances might arise and that a fatal result not only might but would be likely to follow upon his failure to recognise and to deal with them. The administration of anæsthetics by unqualified persons, referred to by Mr. Henslowe Wellington as a fit subject for legislation, is a public danger easily removeable. The present situation is that only persons duly qualified and supervised may sell certain deadly drugs, but that once sold they can be used with more or less dangerous effect by any person who may be rash enough to trifle with them. Inquiry of some kind into his conduct will ensue in all probability if death results from it, but not otherwise.

The Case of a "Canine Specialist."

The Royal College of Veterinary Surgeons is to be congratulated upon having won an appeal of considerable importance to it. Some little time ago it prosecuted under the Veterinary Act, 1881, a man who treated the diseases of dogs at a house in Cambridge-road, Kingston-on-Thames. He displayed his name there on a board, with additions thus: "M. Collinson, Canine Specialist. Dogs and Cats treated for all Diseases." He was not a Member of the Royal College of Veterinary Surgeons and was not on the Register of veterinary surgeons, nor did he hold the veterinary certificate of the Highland and Agricultural Society of Scotland, and he was prosecuted under Section 17 of the Statute referred to, which

Office, educational establishments, &c., £22,600. 5. Medicines, instruments, &c., except as in 1 and 2, £18,000. 6. Barrack services for hospitals, £29,000. 7. Hospital provisions, medical comforts, &c., £115,000. 8. Fuel, light, and water for hospitals, £25,000. 9. Hospital clothing, £2000. 10. Hospital stores and field hospital equipment, £10,700. 11. Works services, except maintenance of barracks included under (1), £81,800. Total, £1,434,700. The following shows the pay and allowances (for servant, lodging, fuel and light, and forage and stabling) per annum of medical officers in the army at home: Surgeon-General, £1447 16*s.* 3*d.*; Colonel, £1008 16*s.* 1*d.*; Lieutenant-Colonel (promoted before Jan. 9th, 1907, and specially selected for increased pay after eight years' service abroad), £802 9*s.* 7*d.*; Lieutenant-Colonel, £711 4*s.* 7*d.*; ditto (after three years' service if promoted on or after Jan. 9th, 1907), £802 9*s.* 7*d.*; Major, £583 9*s.* 7*d.*; ditto (after three years' service as such), £629 2*s.* 1*d.*; ditto (after 20 years' service if promoted before Jan. 9th, 1907, £702 2*s.* 1*d.*; Captain, £372 1*s.* 9*d.*; ditto (after seven years' full pay service), £399 9*s.* 3*d.*; ditto (after 10 years' full pay service), £472 9*s.* 3*d.*; Lieutenant on probation and Lieutenant, £325 19*s.* 2½*d.*; Quartermaster (minimum), £234 14*s.* 2½*d.*; ditto (maximum), £387 5*s.* 10*d.*

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions and admissions to the Indian Medical Service:—Captains to be Majors: Victor Edward Hugh Lindesay (dated July 29th, 1907), Chintaman Ramchandra Bakhle, Roger Parker Wilson, Krisnaji Vishnoo Kukday, Christopher Dering Dawes, Clarence Barrymore Harrison, Nicholas Purcell O'Gorman Lalor, Thomas Henry Symons, Ernest Reinhold Rost, Hugh Ainsworth, Frank Addinsell Smith, John Wolfran Cornwall, Alfred Miller, Frederick Arthur Lucas Hammond, Sydney Price James, and Peter Dee (dated Jan. 29th, 1908). Lieutenants to be Captains: Arthur Francis Hamilton, Arthur Denham White, Michael Foster Reaney, Ralph Koper White, Norman Methven Wilson, John Stevenson O'Neil, Mathew Robert Cecil MacWatters, William Herbert Boalth, George Allick Soltau, John Cunningham, Herman Falk, and Charles Joseph Coppinger (dated Feb. 1st, 1908). To be Lieutenants: Hugh William Acton, Vivian Bartley Green-Armytage, Arthur Norman Dickson, Alexander Glover Coullie, Alexander James Hutchison Russell, Robert Ernest Wright, Dewan Hakumat Rai, William Hunter Riddell, Arthur Batoum Zorab, Arnold Thomas Densham, Frederic Allan Barker, Arthur Waltham Howlett, Arnold Newall Thomas, and Francis Shingleton Smith (dated July 27th, 1907).

The promotion of Major Robert Frazer Standage is antedated to Jan. 29th, 1907.

The King has approved of the retirement from the service of the following officers: Surgeon-General William Richard Browne, C.I.E, (dated April 1st, 1908); Lieutenant-Colonel William Frederick Thomas (dated Jan. 6th, 1908); Lieutenant-Colonel Sir Richard Havelock Charles, K.C.V.O. (dated March 20th, 1908); Lieutenant-Colonel Alfred William Alcock, C.I.E. (dated Dec. 29th, 1907); Lieutenant-Colonel Francis Wyville Thomson (dated Feb. 28th, 1908); Lieutenant-Colonel Frederick George Maidment (dated March 21st, 1908); and Lieutenant-Colonel John Charles Lamont (dated March 10th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Banff: Surgeon-Lieutenant John H. Stephen to be Surgeon-Captain (dated March 13th, 1908). 6th Lancashire: Surgeon-Captain Francis W. Bailey resigns his commission (dated March 9th, 1908). Francis William Bailey (late Surgeon-Captain) to be Captain (dated March 9th, 1908).

Rifle: The Queen's Rifle Volunteer Brigade, The Royal Scots (Lothian Regiment): Surgeon-Major John Pirie resigns his commission (dated March 16th, 1908). 2nd Volunteer Battalion, The Northumberland Fusiliers: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Adam Wilson (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Tyne Volunteer Infantry Brigade) resigns his commission with permission to retain his rank and to wear the prescribed uniform (dated March 4th, 1908). 24th Middlesex Volunteer Rifle Corps: Surgeon-Major Charles Graham Grant to be Surgeon-Lieutenant-Colonel (dated March 16th, 1908).

THE TERRITORIAL FORCE.

An Order in Council published in the *London Gazette* of April 10th gives the names under which certain medical units will be known on transference to the Territorial Force:—

Units of Volunteers.	Units of the new Territorial Force.	Name of County Association.
Aberdeen Companies, R.A.M.C. (Volunteers).	1st Highland Field Ambulance, R.A.M.C.	City of Aberdeen.
Seaforth and Cameron Bearer Company.	Highland Mounted Brigade Field Ambulance, R.A.M.C.	Inverness-shire.
Gordon Bearer Company.	2nd Highland Field Ambulance, R.A.M.C.	City of Aberdeen.
Black Watch Bearer Company.	3rd Highland Field Ambulance, R.A.M.C.	City of Dundee.
Glasgow Companies, R.A.M.C. (Volunteers).	Lowland Mounted Brigade Field Ambulance, R.A.M.C.	City of Glasgow.
Argyll and Sutherland Bearer Company.	1st Lowland Field Ambulance, R.A.M.C.	
Highland Light Infantry Bearer Company.	2nd Lowland Field Ambulance, R.A.M.C.	
1st Lothian Bearer Company.	3rd Lowland Field Ambulance, R.A.M.C.	City of Edinburgh.
Manchester Companies, R.A.M.C. (Volunteers).	1st East Lancashire Field Ambulance, R.A.M.C.	Lancashire.
Manchester Bearer Company.		
North-East Lancashire Bearer Company.	2nd East Lancashire Field Ambulance, R.A.M.C.	
Lancashire Fusilier Bearer Company.	3rd East Lancashire Field Ambulance, R.A.M.C.	
Liverpool Bearer Company.	1st West Lancashire Field Ambulance, R.A.M.C. 2nd West Lancashire Field Ambulance, R.A.M.C.	
Lancaster and Border Bearer Company.	3rd West Lancashire Field Ambulance, R.A.M.C.	Lancashire and Westmorland.
Cheshire Bearer Company.	Welsh Border Mounted Brigade Field Ambulance, R.A.M.C.	Cheshire.
Welsh Border Bearer Company.	South Wales Mounted Brigade Field Ambulance, R.A.M.C.	Herefordshire.
Welsh Bearer Company.	1st Welsh Field Ambulance, R.A.M.C.	Glamorganshire.
South Wales Border Bearer Company.	3rd Welsh Field Ambulance, R.A.M.C.	Monmouthshire.
Leeds Companies, R.A.M.C. (Volunteers).	1st West Riding Field Ambulance, R.A.M.C. 2nd West Riding Field Ambulance, R.A.M.C.	West Riding of Yorkshire.
South Yorks Bearer Company. West Yorks Bearer Company.	Yorkshire Mounted Brigade Field Ambulance, R.A.M.C.	
Sherwood Foresters Bearer Company.	1st North Midland Field Ambulance, R.A.M.C.	Derbyshire.
Leicester and Lincoln Bearer Company.	2nd North Midland Field Ambulance, R.A.M.C.	Leicestershire.
Stafford Bearer Company.	3rd North Midland Field Ambulance, R.A.M.C.	Staffordshire.
Home Counties Bearer Company.	1st South Midland Mounted Brigade Field Ambulance, R.A.M.C.	Buckinghamshire.
Worcester and Warwick Bearer Company.	1st South Midland Field Ambulance, R.A.M.C.	Warwickshire.
Wilts and Dorset Bearer Company.	1st South-Western Mounted Brigade Field Ambulance, R.A.M.C.	Wiltshire.
Gloucester and Somerset Bearer Company.	2nd South-Western Mounted Brigade Field Ambulance, R.A.M.C.	Somersetshire.
Devon Bearer Company.	1st Wessex Field Ambulance, R.A.M.C. 2nd Wessex Field Ambulance, R.A.M.C.	Devonshire.
Bedford Bearer Company.	Eastern Mounted Brigade Field Ambulance, R.A.M.C.	Bedfordshire.
Harwich Bearer Company.	1st East Anglian Field Ambulance, R.A.M.C.	Suffolk.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between April 3rd and April 10th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscribers of Ten Guineas.

William Price, Southerndown, near Bridgend.

Subscribers of Five Guineas.

A. B. Duffin, London.
East Anglican Branch B.M.A., per John Gutch, Ipswich.
T. L. Morgan, Clydach Vale.
South-Eastern Ireland Branch of B.M.A., per R. B. Carey.

Subscribers of Three Guineas.

Sir William H. Bennett, London.
A. G. Davies, Gowerton.
Sir Thomas Smith, London.
T. J. Webster, Merthyr Tydvil.

Subscribers of Two Guineas.

G. Fielding Blandford, London.
J. C. Bowie, Cardiff.
H. Radcliffe Crocker, London.
Bertrand Dawson, London.
Alfred Eddowes, London.
E. P. Evans, Mountain Ash.
Folkestone Medical Society, per J. H. G. Wilgress.
D. Griffiths, Pontardulais, Glam.
G. T. Trevor Jones, Aberdare.
Martin Jones, Aberdare.
H. Betham Robinson, London.
Charles Ryall, London.
Owen Williams, Burry Port.

Subscribers of One and a Half Guineas.

S. and F. Knaggs, Huddersfield.

Subscribers of One Pound, Two Shillings, and Sixpence.

Chorley and District Medical Society, per J. W. Maskell.

Subscribers of One Guinea.

Joseph Ashton, London.
Barton, Hayward, and Ford, Wimbledon.
E. Clifford Beale, London.
E. W. Du Buisson, Hereford.
E. M. Callender, London.
J. Walter Carr, London.
H. W. Carson, London.
F. H. Clarke, Dumfries.
M. C. Corner, London.
John Cropper, Chepstow.
Rhys Davies, Swansea.
J. J. MacWhirter Dunbar, London.
George Eastes, London.
T. Eastes, Folkestone.
G. D. Edwards, Woodford Green.
T. H. Edwards, Huddersfield.
A. Evans, Lampeter.
W. A. Evelyn, York.
J. H. Ewart, Eastbourne.
G. H. Fagge, London.
Percy Flemming, London.
H. T. George, Cardiff.
W. H. C. Green, London.
Cornelius A. Griffiths, Cardiff.
J. C. Guthrie, Tunbridge Wells.
E. L. N. Hopkins, Bedlinog, Glam.
Joseph Hunter, Dumfries.
H. Irving, Huddersfield.
L. G. T.
C. M. Jones, Troedyrhiw.
Dep. Insp.-Gen. L. H. Kellett, R.N., Chatham.
Kidderminster Medical Society, per B. Addenbrooke.
David Lloyd, Newcastle Emlyn.
George R. Livingston, Dumfries.
J. R. Lownds, Newcastle-on-Tyne.
J. B. McCutcheon, Blaengarw, Glam.
David MacEwan, Dundee.
J. J. Macgregor, Cardiff.
W. L. W. Marshall, Huddersfield.
Albert M. Martin, Newcastle-on-Tyne.
Gould May, London.
H. Paterson, Cardiff.
D. R. Price, Ammanford.
R. D. Prichard, Resolven, Glam.
Chauncy Puzey, Liverpool.
C. Reidy, Bargoed.
J. S. H. Roberts, Swansea.
F. W. Robinson, Huddersfield.
J. D. Robson, Dumfries.
Sir Alexander Russell Simpson, Edinburgh.
W. Cecil Sharpe, Matlock Bath.
Thomas Smailes, Honley.
J. Bissett Smith, Ashton-under-Lyne.
A. E. Tonks, Newport, Mon.
Messrs. Trotter, Holmfirth, Yorkshire.
Alice Vickery, London.
N. B. Whitmore, London.

Subscribers of One Pound.

Peter MacDonald, York.
T. W. MacDowall, Morpeth.
E. Rice Morgan, Morriston.
W. T. Rees, Builth Wells.
H. S. Renshaw, Sale, Cheshire.

Subscribers of Half-a-Guinea.

J. W. Ashworth, Heaton Moor, near Stockport.
F. Beaton, Morpeth.
S. Biggart, West Hartlepool.
P. B. Considine, Middlesbrough.
J. W. Cooper, Kenfig Hill.
Kilner Crosland, Huddersfield.
H. Dickie, Morpeth.
J. R. H. Dyson, Honley.
E. R. Evans, Mostyn, N. Wales.
A. L. Foote, Kidderminster.
Ernest H. Fothergill, London.
S. Price Hosegood, North Walsham.
H. J. Hott, Bromley, Kent.
F. J. Jayne, Talgarth.
Francis Johnston, Birkenhead.
W. R. Jones, Senny Bridge.
M. Lloyd, Llanarthney.
Henry C. Martin, Caerleon, Mon.
R. H. Moffit, Aberaman.
Llewellyn Phillips, Cairo, Egypt.
J. P. Philip, Morpeth.
E. S. Robinson, Kidderminster.
Horace Sworder, Luton.
William George Sym, Edinburgh.
J. Meredith Thomas, Merthyr Tydvil.
A. L. Vaughan, Diss.

Subscribers of Ten Shillings.

James Scrase, Newton Abbot.

Subscribers of Five Shillings.

Anonymous.
D. C. Burlingham, Hawarden, near Chester.
Thomas Clifford, Stalybridge.
J. E. H. Davies, Wrexham.
C. I. Faulkner, York.
J. E. B.
George MacDonald, Ruabon.
Edmund Murphy, Cork.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on April 9th, Mr. HENRY MORRIS, the President, being in the chair.

Dr. ARTHUR KEITH was introduced and he made the declaration required on his admission to the office of Conservator of the Museum.

The best thanks of the Council were given to Mr. R. H. Burne for his services in carrying on the duties of Conservator of the Museum during the illness and since the death of Professor C. Stewart and an honorarium was presented to him. Mr. Burne has been anatomical assistant in the Museum since 1892.

The best thanks of the Council were given to Dr. Albert A. Gray of Glasgow for presenting to the Museum his collection of specimens of the membranous labyrinths of vertebrata.

It was resolved to continue the arrangements for supplying tea in the library.

The Jacksonian prize for the year 1907 was not awarded. On the recommendation of the Jacksonian Committee the following subject was selected for the Jacksonian prize for the year 1909: The Treatment of Surgical Affections by Vaccines and Antitoxins.

A vote of thanks was given to Mr. Edmund Owen for having acted as visitor to the examinations of the Egyptian Medical School for the year 1907.

In accordance with the recommendation of the Nomination Committee it was resolved that the deans of the Medical Faculties of the Universities of Leeds, Liverpool, and Sheffield should be informed that the Council, having consulted the several medical schools in reference to the proposal to alter the date of the Primary Examinations for the Fellowship, and having considered the various suggestions made, is of opinion that it is undesirable to make any change. The opinions expressed by the several schools varied greatly. With regard to the spring examination at present held in May, five schools suggested no change, four suggested April, two June, two March, one school suggested March or July, and one July. With regard to the winter examination held in November, seven schools suggested no change, four schools preferred September, and four schools December.

The Council proceeded to elect to the Fellowship Members of 20 years' standing and the two following Members were chosen—Mr. Thomas James Walker, consulting surgeon to Peterborough Infirmary; and Mr. Henry Pottinger Keatinge, director of the Egyptian Government Medical School at Cairo.

Mr. Bernard Pitts was re-elected a member of the Board of Examiners in Dental Surgery.

The PRESIDENT reported the delivery of the Hunterian lecture by Mr. W. Sampson Handley and of the Arris and Gale lectures by Dr. F. A. Bainbridge and Mr. M. Greenwood, jun.

A letter was received from Mr. J. Ward Cousins reporting the proceedings of the Central Midwives Board during the year. The best thanks of the Council were given to Mr. Ward Cousins for his services as the representative of the College on the Central Midwives Board.

It was decided not to hold a Fellows' dinner this year.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING MARCH, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·8 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 9·1, 8·4, and 7·8 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hammersmith, Chelsea, Hampstead, Islington, Southwark, and Lambeth; and the highest rates in the City of London, Registrar-General are, I believe, very valuable. They show us, for instance, that as compared with such a common disease as pneumonia the deaths from anæsthetics are quite trivial in number (41,825 from pneumonia, as compared with 183 from anæsthetics in the year 1906). The figures would be even more reliable if the possibility of having public inquiry in each case could be done away with altogether and the ordinary certificate of death substituted. That the number of deaths from anæsthetics is increasing is perfectly true, but I think that everyone who has had any experience of the surgical activity of late years will support my view that the increase is not even now out of proportion to the enormous number of people who are daily put under anæsthetics for some reason or another. The real difficulty in making a comparison arises from the practical impossibility of ascertaining with scientific accuracy the exact number of operations performed in the course of a year, and no attempt seems to have been made to do so. A very rough approximation might perhaps be arrived at in the following manner. At the hospital to which I am attached there are 221 beds; we manage to keep records of about 70 per cent. of the cases anæsthetised (the balance consists for the most part of dental cases and out-patients that are not admitted to the wards). An average of five years of these records shows that this 70 per cent. represents 770 administrations per annum. It may fairly be said, therefore, that the number of administrations in this hospital of 221 beds is not less than 1000 per annum. Again, I am informed that at the London Hospital last year, with 927 beds, upwards of 17,000 administrations were recorded. It is clear, therefore, that the surgical activity of these two institutions, with under 1200 beds, is not less than 18,000 yearly. If the Medical Directory be consulted it will be found that, excluding the Poor-law infirmaries, the ophthalmic and dental hospitals, and many purely medical charities, at least 36,000 hospital beds are in use in England and Wales alone. Worked out on the above lines I think it may fairly be concluded that there cannot be less than half a million administrations every year. My own impression is that if a proper allowance be made for the above exceptions and for the private administrations undertaken throughout the country one million would not be an excessive figure. This is, of course, only a very rough approximation, but I have ventured to make it, imperfect as it is, because I am convinced that many who talk so glibly about the number of deaths from anæsthetics have not, even in their own minds, attempted to form any conception of the ratio of those deaths to the number of operations actually performed.

Classification.—The next difficulty which arises in connexion with this inquiry is that of assigning to the anæsthetic its exact share in any fatality that may occur upon the operating table. Neither the post-mortem room nor the pathological laboratory affords us any information of a positive character upon this point. In other words, it is impossible to say, by examination of a body after death, whether a patient did or did not die from an overdose of an anæsthetic. The only evidence that we have to rely upon is clinical evidence obtained under conditions of stress and strain which are not conducive to accurate observation or correct interpretation. As examples of the difficulty to which I am now referring I may perhaps instance the following typical cases. A man meets with an accident necessitating an immediate operation, during the course of which he succumbs. In such a case an inquest must, and should, be held, but in my opinion the inquiry should be confined to the "accident" alone and should not be allowed to wander off into side issues as to whether or no the anæsthetic was properly administered. If the latter course be pursued there can be no logical limit to the inquisition; the judgment, skill, and qualifications of the operator must be investigated, as well as the conduct and resources of the institution. From every point of view such a proceeding seems to me intolerable. Again, it is very well known that certain pre-existing conditions render the performance of an operation and the administration of an anæsthetic more dangerous than usual; for instance, Graves's disease, acute septic conditions (especially about the neck), advanced diabetes, status lymphaticus, &c. Of these the pathological condition known as "status lymphaticus" has of late been very prominently brought before the medical world, some people going so far as to assert that its presence, or suspected presence, in any given case should absolutely contra-indicate the administration of any anæsthetic whatever. There can be no question as to the pathology, but the clinical significance of the morbid condition is rather more doubtful, and it is certainly premature to point to any one symptom or sign, such as the swelling of the papillæ at the base of the tongue, as a contra-indication to the administration of chloroform. In this connexion it is not a little curious to note that in the first descriptions of the disease the condition was put forward as an explanation of many cases of sudden death, irrespectively of anæsthetics or operations. In any event it is obviously absurd to assume that the anæsthetic is alone to blame for the deaths which occur in patients who are operated upon in these states, nor should the administrator alone be called upon to bear the brunt of the inquisitorial investigations. In my experience the above cases form the basis of the majority of the sensational reports which appear in the lay press under the heading "Death from Anæsthetics"; not only so, but I am inclined to think that they constitute a considerable number of the deaths included by the Registrar-General under the heading "Anæsthetics for Operation."

There is still a third class of case to which a certain, though I believe a small, number of deaths must be ascribed. I allude to them with some trepidation, but at the present juncture it would not be right to ignore them altogether; I mean the cases in which the death is due to some error of judgment on the part of the operator, or to some unforeseen accident occurring during the course of the operation. Why is the administrator to be made the "whipping boy" in such cases? and how is it possible to avoid doing so unless in every instance the highly objectionable plan be adopted of insisting upon a public investigation in each case that dies during or within a few hours of an operation?

If due allowance be made for the above "borderland" cases, and if the enormous number of administrations be taken into account, I believe that every unprejudiced person must come to the conclusion that the evidence in favour of creating a public scare on this point is insufficient. I am myself much more inclined to the opinion that the public is, on the whole, to be congratulated upon the skill and care displayed in its service, and that the profession has every reason to be proud of the results obtained under difficult and dangerous conditions. I deprecate most emphatically all endeavours to prejudge the point at issue by sensational appeals to the public and protest against its being put forward that "some anæsthetists" *object to* any inquiry being made into their methods and results. It is one of the most cherished traditions of the medical profession that it has never required such *unseemly stimulation* and there is no reason to believe that the administrators of anæsthetics have ever shown themselves behindhand in maintaining this tradition.

Remedies.—Those who are responsible for raising the present discussion have suggested various remedies for what they term the excessive death-rate.

First we have a series of remarkable recommendations made by the coroner for the City of London. The chief proposal is that an inquest should be held in every case of death during anæsthesia (at present some coroners, very properly, I think, exercise a discretion in the matter). Bound up with this proposal are others which, if adopted, would not only place the administrator on his trial before the coroner in every case, but would make the latter the official censor, not only of all hospitals and public institutions, but also of the whole body of the medical profession. This may not have been the original intention of these secondary proposals, but I feel sure that it would be their effect in practice. If once this principle were accepted in regard to one particular department of practice the coroners themselves would find it difficult to resist suggestions to hold an inquiry into all deaths taking place in public institutions. Whether this will ever be considered advisable or not the proposal is, to say the least of it, somewhat premature. It seems also to be proposed to constitute the coroner's court into a sort of scientific "court of inquiry" into the whole question; such a proposal is, of course, simply ludicrous, as anyone who has had any experience of the procedure in a coroner's court must agree.

The next proposal is that it should be made a penal offence for an unregistered medical practitioner to administer an anæsthetic. Apart from difficulties connected with the education of medical students, this proposal must, I am afraid, be looked upon as one of those "counsels of perfection" which it is so easy to formulate and so difficult to put into practice. In the first place, it would involve the repeal and re-enactment of the Medical and

Bethnal Green, Stepney, Poplar, Deptford, Greenwich and Lewisham. A further considerable decline in the prevalence of scarlet fever was recorded last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Stoke Newington, Bethnal Green, Stepney, Poplar, Deptford, Lewisham, and Woolwich. The Metropolitan Asylums hospitals contained 3150 scarlet fever patients at the end of last month, against 4956, 3866, and 591 at the end of the three preceding months; the weekly admissions averaged 336, against 458, 423, and 410 in the three preceding months. The prevalence of diphtheria has also showed a continued decline in recent months; the greatest proportional prevalence of this disease last month was recorded in Fulham, the City of London, Bethnal Green, Poplar, Wandsworth, Greenwich, and Lewisham. The number of diphtheria patients remaining under treatment in the Metropolitan Asylums hospitals, which had been 1168, 1135, and 1184 at the end of the three preceding months, had declined to 1081 at the end of March; the weekly admissions averaged 131, against 155, 150, and 49 in the three preceding months. Enteric fever was slightly less prevalent than it had been in the previous month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Pancras, Bethnal Green, Battersea, Wandsworth, and Greenwich. There were 73 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 119, 96, and 79 at the end of the three preceding months; the weekly admissions averaged 10, against 18, 12, and 10 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Finsbury, Bethnal Green, Stepney, and Greenwich. The 16 cases of puerperal fever notified during the month included two belonging to Fulham, two to Poplar, and two to Camberwell. Of the eight cases notified as cerebro-spinal meningitis two belonged to Finsbury and two to Camberwell.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending March 28th the deaths of 5910 persons belonging to London were registered, equal to an annual rate of 16·1 per 1000; in the three preceding months the rates were 15·2, 17·5, and 17·4 per 1000. The death-rates last month in the several boroughs ranged from 9·8 in Hampstead, 12·4 in Woolwich, 12·8 in Wandsworth, 13·0 in Lewisham, and 13·6 in Fulham, to 19·1 in Finsbury, in Bethnal Green, and in Southwark, 20·3 in Shoreditch and in Bermondsey, 20·6 in St. Pancras, 20·8 in Holborn, and 25·1 in the City of London. The 5910 deaths from all causes included 455 which were referred to the principal infectious diseases; of these, 135 resulted from measles, 50 from scarlet fever, 65 from diphtheria, 135 from whooping-cough, 10 from enteric fever, and 60 from diarrhœa. The lowest death-rates last month from these diseases were recorded in Paddington, Kensington, the City of Westminster, Hampstead, Stoke Newington, and Holborn; and the highest rates in St. Pancras, Fulham, Finsbury, Shoreditch, Bethnal Green, Stepney, and Lewisham. The 135 deaths from measles were 100 fewer than the corrected average number in the corresponding periods of the five years; this disease was proportionally most fatal last month in Hammersmith, Fulham, Hackney, Shoreditch, Stepney, and Lewisham. The 50 fatal cases of scarlet fever exceeded by 20 the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from this disease was registered in St. Marylebone, Finsbury, Shoreditch, Bermondsey, Wandsworth, and Deptford. The 65 deaths from diphtheria were six in excess of the corrected average number for the corresponding weeks of 1902–06; the highest death-rates from this disease were recorded in Fulham, Hackney, Finsbury, Bethnal Green, Battersea, and Deptford. The 135 fatal cases of whooping-cough showed a decline of 54 from the corrected average number; this disease was proportionately most fatal in St. Pancras, Finsbury, Bethnal Green, Stepney, Poplar, Southwark, Greenwich, and Woolwich. The ten deaths referred to "fever" were slightly fewer than the corrected average number in the corresponding period of the five preceding years; of these ten deaths, two belonged to Hammersmith, two to Fulham, two to Greenwich, and one each to Islington, Finsbury, Bethnal Green, and Battersea. The 60 fatal cases of diarrhœa were equal to the average number; the greatest proportional mortality from this disease was recorded in St. Marylebone, Hackney, Finsbury, Bethnal Green, Southwark, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 22 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 98 per 1000. No deaths among children at this age were registered in the City of London. The lowest rates of infant mortality were recorded in Hammersmith, Chelsea, Hampstead, Deptford, and Woolwich; and the highest rates in Paddington, the City of Westminster, St. Pancras, Stoke Newington, Bethnal Green, Southwark, Bermondsey, and Battersea.

THE SERVICES.

APPOINTMENT OF DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE ROYAL NAVY.

Inspector-General James Porter, M.D., C.B., has been appointed Director-General of the Medical Department of the Royal Navy in succession to Inspector-General Sir Herbert M. Ellis, K.C.B., who has resigned. The new Director-General entered the service as surgeon in 1877, was promoted to Staff Surgeon in 1889, and Fleet Surgeon in 1898. In 1900 he was promoted to the rank of Deputy Inspector-General and two years ago he became Inspector-General. He has been principal medical officer at Gibraltar, Chatham, and Haslar, while in a recent issue of THE LANCET we called attention to the constant war services of this distinguished officer. The official record in "The Royal Navy List" is as follows:—

Surgeon of *Orontes* during Egyptian war, 1882 (Egyptian medal, Khedive's Bronze Star); served on shore with the Royal Marine Battalion defending Suakin, from May, 1884, till the battalion was recalled in May, 1885, and was engaged in the operations in the Eastern Soudan, 1884–85; present at the actions at Hasheen, March 20th, 1885; attack on Sir J. McNeil's Zareba, Tulufik, March 22nd; the attack on the square of Guards and Marines, March 24th, and at the taking and burning of Tamaai, April 3rd (Suakin, 1885, To Frek Clasps); landed from the *Doris* during the Boer war, 1899–1900, and was in medical charge between Oct. 20th, 1899, and Oct. 12th, 1900, of the naval forces employed—(1) in defence of Stormberg; (2) in Lord Methuen's advance from Belmont to Magersfontein; (3) in Lord Roberts's advance from Enslin to Belfast *viâ* Klip Drift, Paardeberg, Pretoria, &c.; (4) with General French's column from Belfast to Barberton *viâ* Carolina; medal with eight clasps inscribed "Belmont, Modder River, Relief of Kimberley, Paardeberg, Driefontein, Johannesburg, Diamond Hill, Belfast"; present at Graspan (with the assault), Magersfontein, Poplar Grove, Capture of Pretoria; twice mentioned in despatches; promoted to Deputy-Inspector of Hospitals, November, 1900, for above services; C.B., June 26th, 1902.

We feel assured that the Medical Department of the Royal Navy will be strengthened by all possible means under his dispensation.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Inspector-General: T. D. Gimlette, C.B., to Haslar Hospital. Surgeon: A. R. Schofield to the *Ringdove* on recommissioning. Civil Practitioner: H. H. Jackson to be Surgeon and Agent at Newbiggin. Fleet Surgeons: John Menary to the *Vengeance*, on recommissioning; and H. B. Marriott to the *Doris*. Staff Surgeons: R. W. Stanistreet to the *Pandora* and to the *Perseus*, on recommissioning; C. J. E. Cock to the *Pandora*; and E. F. Mortimer to the *Vindictive*, on recommissioning. Surgeon: H. B. German to the *Vengeance*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Major R. J. Blackham has been appointed to officiate as specialist sanitary officer, Western Area, Southern Command, during the absence on four months' leave of Lieutenant-Colonel Caldwell.

Lieutenant-Colonel Delaware L. Irvine is placed on retired pay (dated March 28th, 1908).

MEDICAL AND HOSPITAL SERVICES FOR THE BRITISH ARMY.

Accompanying the army estimates for the financial year commencing April 1st, 1908, is a statement summarising the total provision made therein for medical and hospital services as follows: 1. Medical establishment (officers, £576,700; warrant officers, non-commissioned officers, and men, £344,900; nurses, civilians, &c., £113,100), £1,034,700. 2. Royal Army Medical Corps, Militia, £21,900. 3. Medical establishment of the Territorial Force, £74,000. 4. Medical staff at War happened to be a small quantity the coroner and jury seem satisfied, and *vice versâ*, not knowing that the amount used is of less importance than the method of using, and that a good administrator may successfully anæsthetise a patient in the same time that a bad one may cause a fatality, although the latter may have used only a fraction of the quantity employed by the former.

I am, Sir, yours faithfully,
J. D. MORTIMER.
April 11th, 1903.

HUMANE SLAUGHTERING OF ANIMALS.

To the Editor of THE LANCET.

SIR,—In the excellent article on this subject in your issue of March 28th I think the description of the Chatham abattoir is somewhat misleading. It is stated "at Chatham the animals are brought to a place just outside the walls of the great hall, here they are felled and then only is a sliding door opened and with the aid of ropes and pulleys the carcass is promptly drawn into the large hall." The method of slaughtering adopted at Chatham is, however, different from this description. The animals are brought into the waiting pens, then taken into the slaughter hall, where they are felled and bled, the carcasses are then dragged into the large meat-dressing room and afterwards conveyed on overhead runners to the cooling room. After each operation the slaughter hall is cleansed from blood and other animals brought in from the waiting pens. This arrangement entirely conforms to the recommendations of the Commissioners on Humane Slaughtering. The slaughter hall is divided into four slaughter pens by dwarf brick walls, thus preventing any animal from seeing another being killed, or from the sight or smell of blood. These walls only extend to half the width of the court, allowing ample space for circulation and the veterinary inspectors, whilst it also allows the superintendent's office to be placed in such a position that this official can have full command over the slaughter hall, practically without leaving his office.

I am, Sir, yours faithfully,
R. STEPHEN AYLING F.R.I.B.A.
Dartmouth-street, Westminster, S.W., April 1st, 1903.

OSCILLATORY CURRENT CAUTERY.

To the Editor of THE LANCET.

SIR,—In the *Daily Telegraph* of April 4th appears a communication from its Paris correspondent upon the experiments now being carried out on wireless telephony at the Eiffel Tower by Dr. Lee de Forest. The final paragraph of the communication is of very great interest to the medical profession generally, so it may be as well to quote the salient points :—

> Incidentally Mr. de Forest has made what may be considered a new discovery. The current from his apparatus had burnt his hands, and he at once concluded that this would be a very simple way of cauterising wounds with electricity and without pain. He made some demonstrations at the Saint Louis Hospital in the presence of Dr. Pozzi and other well-known surgeons, who, he says, were quite enthusiastic over his discovery.

Now, we, in England, are not in the least indebted to either France or America for this discovery, insomuch as it was anticipated in England as far back as December, 1906, when I was experimenting with continuous oscillations of electricity with a view to their therapeutic application. I very soon found that, whenever the retardation was more due to the inductance of the shunt circuit than the capacity thereof, any fingering of the solenoid, constituting the inductance, invariably resulted in the smell of burnt flesh and subsequent destruction of the epidermis of the fingers implicated, and this without any pain at the moment of contact. It occurred to me that, in this phenomenon, we have a means of rapidly and practically painlessly destroying malignant growths, and nævi, situated in spots which are inaccessible to other applications of electric or radio-active measures, such places, for instance, as the inner canthus of the eye.

In order to ascertain the length of time in which such a destruction of tissue would be repaired and in order to give some guide by which we might forecast a cure, on Dec. 28th, 1906, I submitted the first metacarpo-phalangeal knuckle of my right hand for a few seconds to the fat, hot spark from the inductance solenoid. At once and absolutely without pain a small hole was drilled clean through the skin. There was no eschar, as in an ordinary burn, but a simple circular tunnel as if of a drill through steel. I protected the spot by simply covering it from the air and daily watched the process of healing. At first nothing occurred but a very slight moisture or exudation of clear lymph. In about ten days the circumference was slightly raised and elastic and in a little more than a fortnight the exuded lymph formed a scab. At the end of rather more than five weeks the scab fell off and left a smooth skin beneath ; and now, at the end of 15 months, it is very difficult to see where the lesion was produced. I did not immediately rush off to demonstrate this phenomenon, but with British phlegm have been busying myself in steadily perfecting the method, so that it may be used with the greatest effect and with the greatest safety to the patient. The apparatus is now complete.

I do not wish for a moment to detract from the merit of Dr. de Forest's discovery of this phenomenon, which is absolutely original and independent of mine, but I do wish to show that electro-therapeutics in England maintain their place in the front rank and that this so-called new discovery in Paris was anticipated in England at least 15 months previous to the present announcement.

I am, Sir, yours faithfully,
HORACE MANDERS, M.D. Brux.
Harley-street, W., April 6th, 1903.

THE TREATMENT OF "MANIA" (?).

To the Editor of THE LANCET.

SIR,—Dr. Robert Jones's able and thoughtful letter in your last week's edition on this topic must, I feel sure, be welcomed by everyone interested in the treatment of mental disease. More especially must this be the case when it is recognised that after 30 years' experience as a medical attendant in huge asylums for the insane he is so definitely of opinion that "the proper treatment of insanity must be the study of each case upon its merits." This is the gospel I have preached during a period of 35 years' experience of insanity, and that experience makes me more and more impressed with the stern necessity for an intimate study of the temperament, character, and habits of each patient if a successful issue of one's treatment is to be hoped for. Pathological research may some day help us and guide us in our treatment I admit, but in my humble opinion never so much as careful individual clinical study.

Hard and fast rules as to rest, change, drugs, diet, &c., are impossible, and the idea that a physician can in half an hour's consultation map out a definite line of successful treatment in any case of mental disorder is to my mind quite fallacious. I am the greatest believer in "the influence of one mind upon another, whereby qualities such as insight, tact, common sense, inspired by a feeling of brotherhood and sympathy" are made so valuable, but such influence must be the outcome of knowledge of the character, the temperament, and the absolute workings of the mind of your patient. To obtain this knowledge individual attention is necessary, and how this can be gained in the huge asylums of to-day passes my comprehension. The study of the evolution of delusion in many recent cases of insanity is an individual one, and the value of such study cannot be over-estimated.

Dr. Henry Maudsley, in making his munificent offer to the London County Council, has emphasised all these facts, and it is to be sincerely hoped that when the House of Commons has sufficient time to discuss the serious question of the present legalised treatment of insanity it will do all in its power to give facilities for the early and individual treatment of mental disease.

I am, Sir, yours faithfully,
LIONEL A. WEATHERLY, M.D. Aberd.
Bournemouth, April 12th, 1903.

OPEN WINDOWS AND ADENOIDS.

To the Editor of THE LANCET.

SIR,—In one of your annotations last week attention was drawn to Professor William Thomson's observations with regard to cold and damp air. His researches appear to me to corroborate my contention that the method of ventilating rooms by keeping the windows open on cold and damp nights is a serious error. For among other things he points out that dried and heated air has a much more powerful oxidising influence on the blood than cold and damp air. His observations should, I think, be considered by those who on *a priori* grounds believe that open windows in cold and damp weather can have nothing to do with adenoids, unless it be in the way of preventing them. If the various other arguments and figures which I brought forward should not be considered sufficient to establish the fact that children brought up on the open window principle suffer much more frequently

THE RECOGNITION OF THE MEDICAL PROFESSION IN THE ARMY.

Referring to the compliment paid so graciously to Colonel D. Bruce, C.B., R.A.M.C., when Queen Alexandra and the Dowager Empress Marie of Russia visited his laboratory at the Royal Military Hospital recently, the *Army and Navy Gazette* says it "was richly deserved. ...... Early in his career as an army medical officer he came to recognise the extent of the mischief done to human life by diseases which he held to be preventable, and he set to work in a modest way to do what he could to alleviate suffering. At that time the War Office had scarcely been brought to realise that the army doctor had any cause to complain of the position assigned to him in our military system. He was regarded as a 'grumbler' only, no thought being paid to the real reasons for his dissatisfaction with his position—that it gave him no proper opportunities for the exercise of professional skill. When changes came in the attitude of those at headquarters Colonel Bruce was one of the first to avail himself of his chances for prosecuting his inquiries, and the success which has hitherto attended his investigations may be taken as proof of the soundness of the better methods that now prevail."

THE COOKING ARRANGEMENTS AT CHATHAM NAVAL HOSPITAL.

Mr. Jenkins, in the House of Commons, recently asked the Secretary to the Admiralty whether he was aware that at the Chatham Naval Hospital there are at present only one cook and an assistant engaged in serving the 320 patients and nine officers, which results in badly cooked food being served to the patients, thus retarding their recovery; and whether he would take steps to have a more adequate staff provided. Mr. E. Robertson, in his reply, said that the staff actually employed, which consisted of one cook and two assistant cooks, was considered adequate and compared favourably with those at Haslar and Plymouth. He could not find that there was any justification for the suggestion contained in the honourable Member's question. Parliamentary answers are so often evasive that we hardly think Mr. Robertson expected to be understood literally in his reply. Bearing in mind that in a large general hospital, always having a certain proportion of serious cases under treatment, the services of a trained cook are indispensable both night and day, it can scarcely be maintained that the Admiralty scale, as stated by Mr. Robertson, errs on the side of extravagance or even of liberality. And when we compare the number of cooks and cooks' mates allotted in a flagship, for example, to the admiral's mess, ward-room mess, gun-room mess, and warrant officers' mess, it leaves us with the impression that this matter merits careful inquiry by some competent and impartial authority.

SOLDIERS' TEETH.

It has been decided that a soldier who as the result of (*a*) injury received whilst on duty otherwise than through his own fault or (*b*) wound or injury directly attributable to active service incurs loss of teeth may in future be provided with artificial teeth at the public expense.

Correspondence.

"Audi alteram partem."

THE CASE OF CROPPER v. STOKES.

To the Editor of THE LANCET.

SIR,—In reference to the recent action, in which I was defendant, will you allow me to take advantage of your space to thank the numerous kind friends who have interested themselves on my behalf, and especially those gentlemen who have been good enough to sign the memorial to Judge Edge. The case has been already briefly but fully detailed by Dr. B. G. Morison in THE LANCET of April 4th, p. 1031, so I need not enter further into it. All I have to state is that acting under the advice of the Medical Defence Union, in whose hands I fully believed my interests to be secure, I resisted an effort on the part of executors to avoid payment of certain reasonable fees for medical attendance. My action in this case has throughout been perfectly simple and straightforward; the position which I adopted at the outset I still maintain and have nothing to retract. With regard to the judgment itself, as such, I take no exception, although I cannot concur in it. The preponderance of evidence, as is almost unavoidable in many actions of this kind, was on the side of the plaintiffs, and it was perhaps to be expected, although a great surprise to me, that Judge Edge gave a verdict in their favour. I submit, however, that a mere deficiency of evidence is not sufficient basis on which to found the denunciations which were levelled against me. I maintain that his remarks, which have caused me great pain and annoyance, and very probably injury as well, were entirely undeserved by me and were not justified by the circumstances of the case.

I am, Sir, yours faithfully,
Highbury-place, N., April 13th, 1908. H. FRASER STOKES.

DEATHS DURING ANÆSTHESIA.

AN ANÆSTHETIST'S POINT OF VIEW

To the Editor of THE LANCET.

SIR,—At somewhat irregular intervals the question of the mortality which occurs from or during the anæsthetic state becomes the subject of acute discussion in professional circles. On the last occasion (about 18 years ago) the point at issue was simple and scientific and strictly germane to the subject of anæsthetics; it was whether the immediate cause of death was cardiac or respiratory failure. At the present moment there seems to be a tendency to start another discussion upon "Deaths under Anæsthetics," but from the way the matter has been raised the side issues involved seem to have become of far greater importance than the original question itself.

Statistics.—Complaint is made that the figures furnished by the Registrar-General afford no criterion of the number of deaths which actually occur during the inhalation of an anæsthetic. But even if such be the case, it only tends to prove that those who furnish him with his facts hesitate to put down under this particular head cases in which there is a reasonable doubt as to the immediate or most important cause of death. It would surely be much more misleading to include under the heading "Anæsthetics for Operation" such cases as severe accident or advanced disease. In this, as in any other case, the figures of the Registrar-General can only be used for purposes of comparison with other causes of death or with deaths from the same cause in other years. It seems to me that it would be just as reasonable to complain that the figures given for the deaths from pneumonia or scarlet fever for any one year are inaccurate because the diagnosis might be open to question in some cases and, in any event, had not been verified by a coroner. Used in the way I have indicated —i.e., for purposes of comparison—the figures of the

As a consequence of the decrease of disease among the loose women of the town the Würtemberg army is the purest of the German Empire. The number of Würtemberg soldiers contracting venereal disease during the course of a year only amounts to 6·4 per 1000. On the other hand, the Prussian, Saxon, and Würtemberg army included give an average of 19·4 cases per 1000. In the French army the proportion is 29·9 per 1000; in the Austrian army 57·5 per 1000; in the Italian 91·5 per 1000; and in the British army 122 per 1000. For ten years now the Würtemberg army has shown the lowest figures in regard to venereal disease. This is probably due to the method of constantly arresting not recognised prostitutes but any woman who is suspected and of examining not merely for syphilis but also for gonorrhœa. A small platinum spoon is introduced in the urethra to collect secretions for microscopic examination; also after the menses the cervical secretions are examined for gonococcus. The full details concerning every woman examined are carefully entered in a register, so that a complete sexual history is kept. Red strokes relate to syphilis and blue strokes to gonorrhœa. Such records spread over many years and by the coloured lines reference is quickly made. When a woman is found to be diseased she is forced to go to the hospital. Here there is a special ward and these patients are carefully separated from the other female patients. If the nature of the disease is not infectious the woman may be treated at home but the attendant medical adviser must certify to the police once a week that there is no danger. Finally, it should be mentioned that there is a female member of the police force present at the examinations of the women, and she endeavours to persuade them to lead a better life.

Of special interest to the British public is the history of the Stuttgart public slaughter-house. In England the whole question of meat-supply has to be dealt with and the experience at Stuttgart may be considered useful as showing "how not to do it." According to old church records a public slaughter-house was built at Stuttgart in the year 1509. A stone bearing an inscription still remains and it is dated 1585. The words carved in the stone are:—"Oh! flish das ider meizer Tesh nit alzeit Pflung hut das rech ich Got," which might be translated as: "Oh! flesh that in the butcher's pocket not always has *fins* that I leave to the revenge of God." In other words, Divine wrath is called down on the unscrupulous butchers who attempt to sell diseased meat. It would seem as if the slaughter-house remained public or municipal property up to July 18th, 1738, when it was sold to the Butchers' Union for the absurdly low price of 600 florins. In those days, and for many years, only sufficient cattle were killed for the needs of the town. But in the course of time and as the facilities of communication increased people came from the outskirts for their provisions. The accommodation then became insufficient. The slaughter-house was too small and a nuisance to the neighbouring dwellings. Therefore in 1866 the Butchers' Union built an abattoir near the King's wood garden which was intended only for the slaughtering of cattle. In time, however, the city authorities interfered and ordered the butchers to take the smaller animals, such as sheep, to the abattoir. As early as 1869 the accommodation of the new slaughter-house was already found to be totally insufficient. Not only were cattle from outlying districts brought in but they arrived from abroad, from Holstein and from Russia. New stabling had to be provided and the Butchers' Union built a stable for 200 cattle some distance away. In the course of time, and enlightened by the example of other German cities where the building of municipal abattoirs had proved so great a success both from the sanitary and from the financial point of view, the municipality and people of Stuttgart realised what a serious blunder was committed when the public slaughter-house was sold to the Butchers' Union. But now a vested interest had been created and it could not be abolished without making great sacrifices. The abattoir monopoly, which had been sold to the Butcher' Union in 1738 for 600 florins, was bought back by the city for the sum of 775,000 marks. It was in 1890 that the city determined to build a modern and model abattoir with a cattle market large enough to satisfy the requirements of a population of 380,000 inhabitants. The contract stipulated that the city might take possession of the abattoir belonging to the Butchers' Union in 1900 and use it until they had built their own which is to cost 5,000,000 marks (£204,000).

When the new abattoir is ready for use the fees charged for slaughtering will be increased, for the slaughter-house must be made to pay. Some years ago a municipal commission made special arrangements with the butchers to establish a price for the retail sale of meat. This meat tariff does not work well. The butchers consented to its establishment so as to get rid of the *octroi* or town dues that used to be levied on all animals brought in. The Stuttgart *octroi* was abolished in April, 1905, and the tariff for the sale of meat has four years more to run and will probably not be renewed. In 1849 and at other times the State and the local authorities have endeavoured to fix the retail price at which meat should be sold, but it does not seem to work satisfactorily. Laws of Jan. 12th and March 30th, 1905, appointed the commission to regulate the price of meat. A veterinary surgeon nominated by the city presides; then there are one member of the Butchers' Union, one representative of the cattle dealers, one representative of the dealers in smaller animals, and the business manager or economic superintendent, as he is called, of the slaughter-house. This commission met no less than 153 times in 1906. Not only is the price of meat fixed but great care is taken to see that it is only sold when sound and in a wholesome condition. Thus in 1906 there were at Stuttgart 247 retail butchers and they received 2878 surprise visits from inspectors. Then there are 885 retail stores, not regular butcher's shops, but places where some kinds of meat, and more especially sausages, are sold; the number of visits and examinations made amounted in all to 8885. At the 14 fish and poultry dealers 167 inspections were made. At the public market and during fairs 35 more inspections took place. Thus, taken altogether, commendable activity was displayed. Yet with all this only in 165 cases was it found necessary to prosecute and these proceedings were nearly all settled by the payment of fines.

Though the butchers will have to pay higher fees for slaughtering in the new abattoir, this will be compensated by the much greater profits which it is believed that they will derive from the bye-products. They have been authorised to form a trust for the conjoint working of the various industries connected with these bye-products and this is one of the most profitable phases of the whole business connected with the slaughtering. The municipal statistics show what is the extent of the abattoir business and also they demonstrate the increase of poverty and depression in Germany. In 1905, 142,402 animals (weighing 12,252,398 kilogrammes) were slaughtered, but in 1906 there were only 138,281 animals (weighing 12,187,409 kilogrammes) slaughtered. This, in spite of a constantly increasing population, indicates a falling off in the consumption of meat which in 1906 amounted to 64,989 kilogrammes. If Cannstatt and the other suburbs are included, the grand total is 162,652 head in 1905 and 156 970 in 1906, or 5683 animals less. But what is more significant than the number of animals killed for food is the character of these animals. A far greater proportion of cows and heifers were brought in for slaughter. Then, as there is more poverty and therefore less demand for the expensive portions of meat, many of the best cuts are imported from the surrounding districts. Now of the animals killed in 1905, the number found to be diseased was 21,527; but in 1906, out of a smaller number killed, a greater number were diseased—namely, 22,865, showing an increase of 1338. In 1906, there were 7528 cases of tuberculosis, as against 6533 in 1905, an increase of 998. Of these animals, after destroying the diseased parts, there were left for consumption 21,697 kilogrammes in 1906 and 20,373 kilogrammes in 1905, an increase of 1324 kilogrammes. Of what was left to be sterilised and cooked by the *Freibank* there was no change worth mentioning—1036 animals in 1905 and 1065 animals in 1906, an increase of only 29 animals. The number of animals that are totally destroyed as absolutely and in every part unfit for food is, of course, less where the *Freibank* exists, though it is doubtful if the British poor would consent to purchase food known to have been diseased, however carefully it might be sterilised. With the increase of distress the number of horses, as well as of inferior cattle, consumed as food naturally augmented—namely, 277 in 1906, as against 255 in 1905; but counting the carcasses brought in from the outside there was an increase of 26 horses used as food in 1906.

Finally, the financial situation must be considered, and the growth of abattoir business may be illustrated by the fact that the fees paid for slaughtering amounted to 8335 florins in 1866, to 67,763 marks in 1876, to 60,491 marks in 1866, to 88,317 marks in 1896, and to 105,900 marks in 1906. If we take the budget for this last-mentioned year the

Dental Acts, for, as is well known, these Acts do not forbid anyone to practise; they merely afford a *minimum* of protection to the public, and indirectly to those who are duly qualified. I quite agree, of course, that it is very desirable that the Acts should be re-enacted in this sense so as really to protect the public and discourage quackery, but I can hardly believe that it will be possible to do this on the side issue of anæsthetics. Nor am I quite convinced that the advantage, as far as anæsthetics are concerned, would be worth the trouble involved. I am extremely doubtful whether many administrations are undertaken by unqualified people in the present day, the risks are too great, and it is even more doubtful whether many, if any, deaths can be attributed to this form of illicit practice. I have no doubt, too, that a good deal of opposition will be met with from the dental side unless the holders of the L.D.S. are specifically included in the term "registered practitioner." In these circumstances it does not seem to me to be very dignified or wise "to cry for the moon."

The proposals which have my most hearty sympathy are those which urge upon the medical examining and educational bodies the absolute necessity of affording the medical student additional facilities for obtaining experience and practice in this particular branch of practice. The proposals now made run very much upon the lines laid down by me in a paper published in THE LANCET of May 28th, 1892, p. 1176. Since that date the Society of Anæsthetists has been largely instrumental in obtaining considerable improvement, but no doubt there is still room for more to be done in this direction, and I gladly welcome the revival of the movement. As an addendum to the education of the medical student I would myself put forward the importance of educating the public. The lay mind is apt to run from one extreme to the other in anæsthetic as in other matters—from carelessness to abject fear—and I am not quite sure which is the worst condition.

Under the head of carelessness I would include insistence upon being given an anæsthetic for trivial examinations and operative procedures; the demand which patients sometimes make for chloroform for simple tooth extraction, and the occasional development of the "chloroform habit" in those who suffer from neuralgic pains. But the form of carelessness to which I would particularly draw attention is that in which a patient who is about to be operated upon ties the hand of the operator and embarasses the practitioner in attendance by insisting upon the latter giving the anæsthetic. I firmly maintain that this is wrong, and that only in exceptional circumstances should the anæsthetic be given by anyone who has a personal or professional interest in the operation to be performed, the danger being, of course, that his attention is apt to be distracted from the anæsthetic to the work of the surgeon. I do not in any way wish to imply that a specialist should always be called in, that is often quite impossible and unnecessary, but I do think that in such cases a neighbouring and disinterested practitioner should be asked to undertake the responsibility. As an example I may perhaps briefly relate a personal experience. A good many years ago I gave an anæsthetic for the examination of a lady by a particularly enthusiastic gynæcologist. A considerable degree of relaxation was necessary. On passing the speculum a very interesting and unusual pathological condition was discovered and nothing would content my enthusiastic friend but that I should come to the foot of the bed and look at the curiosity. On my return to my proper position I found the patient slightly livid and the respirations obviously failing. Slight pressure on the chin, &c., quickly restored matters, and at this distance of time I cannot remember exactly whether *anyone* but *myself* was aware of the jeopardy in which the patient's life had been placed, but I think not. This exemplifies what may, and I believe often does, occur, and I was that day taught a lesson which I hope I shall never forget. This too, I fancy, is one of the reasons why accidents are more common at the hands of the junior members of the profession, who are generally much more keen about the surgical procedures than about the somewhat monotonous process of administration. In hospital practice especially some of the most troublesome cases are those in which the patient comes to the operating theatre in a condition of mortal dread of the anæsthetic. It is in such cases that extremely sudden, and I believe quite unavoidable, death is apt to occur in the practice of any anæsthetist, however great his skill, however large his experience; it is the sword of Damocles that hangs over the head of each one of us. To a great extent this state of terror is engendered and enhanced by the sensational paragraphs and headlines of the lay press and by the injudicious utterances of people "clothed in a little brief authority," against which I would earnestly protest.

The City coroner suggests that a Royal Commission should be appointed to consider the question of deaths under anæsthetics. If the terms of reference to such a commission could be so arranged as to include an inquiry into the desirability of adopting the Scotch inquisitorial system, or, at any rate, of holding the coroners' courts *in camerâ*, I fancy that the medical profession would nearly unanimously accept the suggestion.

I am, Sir, yours faithfully,
J. FREDK. W. SILK, M.D. Lond.,
Anæsthetist and Teacher of Anæsthetics at King's College Hospital.
April 11th, 1908.

To the Editor of THE LANCET.

SIR,—I have thought that the outcome of a fairly extensive experience, not only as an anæsthetist to general and special hospitals but also as a general practitioner, may be worth contributing to this discussion. I would say that I agree thoroughly with every proposition laid down by Dr. J. F. W. Silk and in the main with those of Mr. H. Bellamy Gardner, but I would limit their application to administrations conducted by those who can claim to be considered specialists. As regards the knowledge, either theoretical or practical, of the "average medical man"—recently qualified or otherwise—I have been driven to conclude that there is much room for improvement and that many belong not merely to "those who don't know" but to that much more dangerous class "those who don't know that they don't know." Mistakes are commonly committed and remarks are commonly made which show only too evidently an ignorance of the first principles of the subject. Cases have occurred, even fatal ones, in which an anæsthetist of any experience would have foreseen great difficulties, whereas he by whom the duty was undertaken obviously failed to do so and was unable to cope with them when they arose. Although it is true that faulty administration is comparatively very seldom the direct or sole cause of death, one hears much too often of instances where it has caused considerable anxiety and materially interfered with the success of the operation.

Until the examining bodies take this matter more seriously I am afraid one cannot hope for much alteration. In the stress of preparation for examination a student can hardly be expected to trouble much about a subject which, as he would say, "does not pay," for even when instruction is required there is little probability that a single question will be asked, and if it be that much importance will be attached to his answer. This has an unfortunate effect as regards the inability of many practitioners and men on the junior staff to give an anæsthetic for a simple operation without causing discomfort to the patient and trouble to the surgeon, even if worse results be avoided. But when improvement takes place the fact will still remain, as pointed out by "F.R.C.S." in THE LANCET of Feb. 8th last, that "for the proper conduction of a large proportion of operations done at the present time special skill and experience are as needful in the anæsthetist as in the surgeon, and the average practitioner cannot expect to be any more capable of replacing the one than the other."

Practitioners in this country are not usually expected to undertake a lithotrity or a gastro-jejunostomy, and it should be more generally realised by them, and by such surgeons as *Dr. T. D. Luke* describes, that for the average medical man the field of anæsthetisation has its limits no less than the field of surgery. It seems to me, therefore, that every student should be made to go through such instruction as would enable him to act in cases not requiring special skill and should be made aware of the circumstances under which special skill is needed and should be procured except in emergencies. I do not see how more can be accomplished during the ordinary five years' course, but his knowledge to this extent should be thoroughly tested.

As regards the present system of inquiry into deaths which have occurred during anæsthesia, it can hardly be doubted that it is unsatisfactory, and Dr. F. J. Waldo's paper only strengthens this impression. On reading the reports one cannot help being in many cases struck by the futility of the questions and by the danger of the little knowledge possessed by the coroner. For example, the administrator is often asked, "How much chloroform did you give?" and if this it was decided to recommend the education committee to arrange for the inspections to be carried out by the medical officers of health. *It does not seem to have been considered necessary to provide for any general supervision or control of the inspections.* This is to be regretted and it will be a great mistake if any attempt is made to collate the reports of the inspecting medical officers in the offices of the committee by an official who is not a medical man and who would not therefore be able to appreciate the importance of the results that it is anticipated will be obtained by the systematic inspections which it is proposed to make.

Special Accommodation for Convalescent Lunatics.

The chairman of the committee of visitors of the Three Counties Asylum for Carmarthenshire, Cardiganshire, and Pembrokeshire recently proposed to the committee that arrangements should be made for the treatment in a separate building of those patients who it might be expected would within a reasonable period be restored to health. He expressed the opinion that it was especially depressing for this class of patient to be constantly associated with those whose condition was hopelessly incurable. In order to give practical effect to his proposal he suggested that a new house should be built for the medical superintendent whose present residence might then be utilised for the convalescent lunatics.

Flogging Sentences at Glamorgan Assizes.

The large number of robberies with more or less violence which have occurred in the streets of Cardiff has been a matter of concern for some time not only to those whose business it is to keep down crime but also to those residents who have been obliged to traverse certain parts of the borough in the neighbourhood of the docks and in the centre of the town. During the past year there have been no fewer than 27 persons committed for trial for the offence referred to. It is satisfactory, therefore, to find that at the assizes held at Cardiff Mr. Justice A. T. Lawrence has shown his determination adequately to punish those who are convicted before him of such a crime by sentencing them not only to terms of imprisonment but to receive in addition a flogging with the cat. In sentencing one prisoner who had been found guilty of brutally assaulting and robbing a haulier his lordship said: "It is a very serious offence and one I should not be doing my duty if I did not attempt to repress as far as lies in my power. I know there are some humanitarian people who object to the use of the lash, but when we have to do with persons of *your class I do not think there is* any other way of teaching you and of convincing you that it is a game that is not worth the candle. You must know that if you come to this court for committing a robbery with violence you will assuredly suffer not only imprisonment, about which you do not appear to care very much, but also by your person receiving chastisement."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Suggested Colony for Sane Epileptics in Scotland.

AT a recent meeting of the adjustment committee of the parish councils of Edinburgh, Glasgow, and Govan, a remit was submitted from Edinburgh parish council in favour of the establishment by joint action of the three parishes and of other large parishes in Scotland of a colony for the treatment of sane epileptics. From the returns it is seen that at Jan. 1st, 1900, there were in Scotland 443 chargeable sane epileptics, and returns from the three parishes for 1905 showed that the number chargeable in Edinburgh was 29, in Glasgow 74, and in Govan 46, making a total of 149. Out of this total 15 from Edinburgh, 34 from Glasgow, and 20 from Govan were recommended as suitable for the proposed colony. It was decided by the committee that the figures relating to the three parishes did not justify any urgent necessity for the establishment of a joint colony, and also that in view of the Royal Commission on the Poor-law and the Feeble-minded further consideration should be deferred.

The Water-supply of Aberdeen: Important Report.

There have just been issued to the members of the Aberdeen town council copies of the report prepared by *Professor* D. J. Hamilton and Professor Matthew Hay embodying the results of their examinations of the water-supply of the city. The report shows that chemical and bacteriological examination of the water-supply was carried out weekly for a period of 14 months, commencing with November, 1906. The water, as was already well known, was found *to contain a remarkably* small proportion of saline matter and is in that respect much above the usual *standard of water-supplies.* During the first three months of 1907 there was a somewhat curious increase of chlorides to nearly double their usual amount. This was apparently not due to sewage pollution, *however, for a sample of water from the Dee* above Braemar gave also an increase of chlorides. The amount of "free ammonia" and of "albuminoid ammonia" was usually within the limits for a potable river water, but on some occasions the limit for albuminoid ammonia was exceeded. As regards the bacteriological examination the results were more decisive, especially in reference to the bacillus coli. The number of germs or germ colonies growing at 20° C. varied from 90 to 2770 in one cubic centimetre of the water, but both these figures were exceptional, *the usual range being from about 200 to 700.* The maximum limit for *a good river water* is usually stated at 500. The number of germs growing at the temperature of the human body varied from 2 to 58, but was seldom above 20. The maximum limit for a good river water is put at 50. The bacillus coli was on many occasions detected in as little as one cubic centimetre of the water, whereas really first-class water should not give evidence of the bacillus coli in the centrifugal residue of 100 cubic centimetres of water. Much of this pollution is probably due to surface drainage from grazing lands occupied by cattle or sheep and to cultivated land that has been recently manured, but part is *almost certainly due to* domestic sewage. Professor Hamilton and Professor Hay conclude their report as follows. "In view, therefore, *of the results* of our examination of the water-supply and of our knowledge of the impracticability of adequately protecting the river *against* domestic pollution, we have no hesitation in expressing the opinion that the water-supply of the city in its present *condition* is dangerous, and that steps should be taken *either to* filter the water or to obtain a supply from a source *not open to* domestic pollution. Filtration of the present *supply* is, in any case, advisable in order to remove the turbidity which is so frequently observed after wet weather."

April 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland: Election of Examiners.

A MEETING *will be held on Tuesday,* May 5th, at 4.30 P.M. to elect examiners. Graduates of any University which may be *from time to time recognised* by the College will be eligible for election as examiners in the subjects of general education. All the other *examiners* will be Fellows or Licentiates of the College or *professors or lecturers* in any school of medicine recognised by the College. Candidates are requested to lodge their applications in writing with the registrar, at the College, on or before Tuesday, April 28th, at 10 A.M.

Dublin Abattoir and Slaughter-houses.

The claims of the Dublin abattoir on popular favour are about to be tested sharply. The expenditure *on that* institution is said to increase, while the income is surely decreasing, and *so* "the concern is farther off than ever from paying its expenses." So says the report of the estates and finance committee of the corporation of Dublin *for the* year ending March 31st, 1908. Three causes have been assigned by the superintendent, each of which is of high interest to the public from both the sanitary and the financial point of view. 1. *The tolls from the* army authorities have dropped from *50s. weekly to 10s. The contractor* was bound to kill there all the animals of which the meat was supplied to the army; *the change made in the* contracts results in the supply of tinned meat in the proportion indicated by the above-*mentioned decrease of* tolls. 2. The second, "perhaps the most important, cause, and one which is remediable, it *appears, is the system* adopted by a large number of owners of private slaughter-houses of subletting their premises *either at a* weekly rent or at so much per head of cattle slaughtered. This system, which is largely on the increase, *has a very serious* effect on the earnings of the abattoir." A from adenoids than those who sleep with closed windows, it may at least be admitted that they, together with Professor Thomson's observations, show that serious and immediate attention should be given to the subject. The hope was expressed that Professor Thomson's paper would be "carefully considered and its lessons acted upon." To do this surely we should be justified in advocating that windows ought not to be kept open on cold and damp nights, in the sleeping rooms of children at least. I believe that from 80 to 90 per cent. of "adenoids" could be almost immediately prevented by the promulgation of this doctrine, for there is no doubt that mothers would willingly adopt it at once if they had the sanction and authority of the medical profession. I am, Sir, yours faithfully,

Wimpole-street, W., April 13th, 1903. J. SIM WALLACE.

SMALL-POX AND DISINFECTION ON BOARD SHIP.

To the Editor of THE LANCET.

SIR,—Your correspondent "J. F. B.," whose letter on the above subject appeared in your issue of March 21st, asks for reference to articles or records of experiments indicating the value of formalin as a disinfectant in such circumstances. Klein, Sommerville, and others have done experimental work on the germicidal efficiency of formalin. In the *British Medical Journal* of July 2nd, 1904, experiments are recorded by Sommerville in which formalin is put in competition with carbolic acid in the destruction of B. typhosus and the results show that the coefficient of formalin is 0·4, taking that of carbolic acid as 1·0. In the *Sanitary Record* of Nov. 29th, 1906, Sommerville and myself, working with a modification of the above method, in which various organic matters (serum, gelatin, mucin, &c.) are introduced, record a coefficient for formalin ranging from 0·2 to 0 3; and in the same journal of May 9th, 1907, working with larger quantities of organic matter, we find the same coefficient for this body—viz., 0·2 to 0·3.

It is clear that fumigation with any body of such low germicidal strength must be a most unsatisfactory method of disinfecting ships. The same remark applies to fumigation with SO_2. Nearly 30 years ago the whole question of the disinfectant value of this gas (SO_2) was investigated in Germany by Koch, Wolfhügel, Hüppe, and Proskauer, and the report of these experts stated that sulphur dioxide, with or without water, dry or damp, was entirely useless for the disinfection of spores and quite unreliable for the disinfection of sporeless organisms in the presence of any superficial protection. It was further demonstrated that in practice the unequal diffusion of the gas and its loss through various causes rendered the disinfectant value much less than in the laboratory experiments, and these scientists strongly recommended that disinfection by sulphur dioxide should be entirely abandoned. Dujardin-Beaumetz, Cassedebat, Sternberg, and others have described the use of this gas as wholly unreliable, a farce, and simply ridiculous. The vapours of formalin and sulphur dioxide, lacking, as they are, so largely in germicidal efficiency, are now superseded by the application of liquid disinfectants of high coefficiency. A mop or spray and warm watery dilution of one of these form the most effective implements for the disinfection of the various apartments, berths, &c., aboard ship.

I am, Sir, yours faithfully,
J. T. AINSLIE WALKER, F.C.S.

Kew Gardens, April 11th, 1908.

SUSSEX MILK-VENDORS FINED.—The sequel to samples of milk from Sussex being taken at Thornton Heath station, London, at the latter end of February, came before the Croydon magistrates on April 7th, when the Etchingham Milk and Cream Company, Limited, and John Everatt, of Cooksbridge, were fined, the former company £3 and costs and the latter defendant £2 and costs, for selling to retail dealers milk deficient of fat. In the case of the defendant company it was stated that the railway company (the South-Eastern and Chatham Railway) had complained of the condition of the churns; and in the other case the defendant said that he did not seal his churns because the railway company (the London, Brighton, and South Coast Railway in this case) reserved the right to inspect them. 8 per cent. of added water was found in the sample of milk from Cooksbridge and in the other case the milk was deficient of 40 per cent. of fat.

SANITATION AND THE SLAUGHTER-HOUSE AT STUTTGART.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

WINE FOR THE POOR.—MEDICAL INSPECTION OF SCHOOL CHILDREN.—SUCCESSFUL MEASURES AGAINST VENEREAL DISEASE.—THE WÜRTEMBERG TROOPS THE LEAST CONTAMINATED.—SALE AND RE-PURCHASE, AT GREAT LOSS, OF THE ABATTOIR.—INSPECTION AND CONTROL OF MEAT.—THE COST.

STUTTGART among its many attractions affords points of special interest to the student of sanitation. By reason of its importance and population it holds the twelfth place among the 36 largest towns of the German Empire. Since 1877 its medical officer of health has not been allowed private practice but must devote his whole time to the public service. In 1883 a second medical officer was appointed whose principal task is to attend to prostitutes and to prevent the spread of venereal disease. A third medical officer was nominated to superintend the insane and the poor-house. Finally, in 1903, a bacteriological institute was established. The chief medical officer of health has to watch over the work of the other officers. He has also to instruct and to advise the town councillors and the police in all matters relating to insanitary dwellings, drainage, factories, milk, food, and drug supplies, the care of the insane, &c. The city, which used to consist of only seven, has now 14 wards. There are several "doctors of the poor" who receive from the municipality £25 a year and have to give full medical attendance to the indigent living in their wards. They also have to advise in regard to the care of orphans and decide the amount and nature of the relief that should be given. Thus, in 1906 the food given to sick persons amounted to 13 500 portions and 4551 litres of wine. From this it will be seen how in Suabia wine is considered an important article of diet and a help in restoring the strength of the sick; indeed, this is another illustration of the fact that in wine-growing countries the fear of intemperance is not entertained.

In regard to the medical inspection of school children the question has not been neglected, but at the time of my visit the authorities were waiting to discover the right way of organising this service. There was a risk of a conflict of authorities. Dr. Krauss, the first medical officer of the city, was sent all over Germany to study what had been done elsewhere, but the results of his investigations were not at all satisfactory. In the meanwhile the chief medical officer of health receives twice a year in his own surgery all the school-children. The first examination is very thorough and conducted for the purpose of discovering any constitutional defect. If this is found, the medical officer decides whether the child should be sent to the salt baths, to a school colony in the country or on the hills, or what other mode of treatment is necessary. Whatever has to be done, it is done forthwith. The cost is at once defrayed by the city but the public authorities sometimes endeavour to recover the whole or part of the outlay from the parents. Also the cost is at times in part met by the insurance to which the parents contribute. In any case the treatment of the child is taken in hand at once and this is not delayed by questions as to who should pay the cost.

It is, however, in coping with venereal disease that the authorities at Stuttgart have been most successful. The system adopted differs considerably from that which prevails in most other towns. There are in Stuttgart, in spite of its population of 260,000 persons, only 16 women regularly inscribed as prostitutes. These women voluntary inscribe themselves so as not to be troubled by the police and present themselves for periodical examination. The real measure of protection adopted is that of establishing a very careful watch in the streets. Whenever there is reason to believe that a woman is practising prostitution she is arrested and examined. In 1906, the last year for which I was able to obtain figures, 1172 women were thus examined. Of these, two had soft ulcers; 118 had gonorrhœa, and of these 15 had syphilis as well; and there were 45 cases of syphilis. Thus there were 180 cases of venereal disease out of 1172 women examined. This represents a considerable decrease as compared to the figures given some years ago. The percentage of disease is now reckoned as 0·17 per cent. soft ulcers, 11·3 per cent. gonorrhœa, 5·1 per cent. syphilis; total, 16·6 per cent.

border of small vesicles, was excised, serum was administered twice, and the patient is doing well. It is believed that the disease was contracted when the man was working at a city hide store, in which some hides were being prepared for shipment. None of the workers in the same place up to the present are affected.

Hospital Abuse in Belfast.

For some time past there has been considerable dissatisfaction expressed by both general practitioners and hospital staffs in Belfast that people who are quite able to pay medical men receive gratuitous advice at the Belfast hospitals, more especially in the extern departments. Certain circumstances have accentuated this feeling. In the first place, there is undoubtedly a tendency always in a place like Belfast—where there is a medical school—to a plethora of medical men, and for the same reason a large number of medical men will be found specialising in every department. Further, the present business depression, due to the staple industry of Belfast—linen—being in a very unsatisfactory condition owing to the American money panic, has not improved matters for the medical profession. During the year 1907 there were 29,433 extern patients in the Royal Victoria Hospital. Some days the numbers exceeded 400, and the extern surgeons and physicians, struck with the fact that well-to-do people were sometimes attending, brought the matter before the medical staff and board of management with the result that a joint sub-committee of some of the staff and some of the board of management was formed to consider the matter, and after some very harmonious meetings decided [1] that the arrangement in regard to 1*d.* a week subscribers of *bonâ fide* working classes should remain as before. For at the various works in Belfast by paying 1*d.* weekly to the funds of the Royal Victoria Hospital the workers can themselves and their families be treated in the extern department or admitted to the wards, except when suffering from tuberculosis or any infectious disorder. A plan was adopted at the hospital many years ago under which obviously necessitous cases are treated on their merits and subscribers' "lines" should be given only to such necessitous people. Other patients should present a written communication from their own medical men. It was also arranged that when a case came to the extern department (not necessitous, or 1*d.* a week subscriber, or with an annual subscriber's recommendation) he or she should be examined and his or her medical attendant should be asked if the patient ought to be treated by the charity. Finally, it was agreed that the following notice should be hung up in the extern department of the Royal Victoria Hospital:—

NOTICE.

This is a charitable hospital and medical and surgical treatment is only intended for those who are unable to pay for it elsewhere. The visiting medical and surgical staff give their services free. It is desirable that patients should come to the hospital provided with either a subscriber's ticket or a note from their usual medical attendant.

A discussion was held on Hospital Abuse on Feb. 20th,[2] at which it was reported what steps had been taken by the staff of the Royal Victoria Hospital, and it was decided to send a circular to the practitioners in Ulster asking them to second the efforts now being made by the staffs of the various charitable hospitals to reduce hospital abuse by taking steps to prevent well-to-do patients from coming to these institutions. A small subcommittee of general practitioners appointed at this combined meeting of members of the Ulster Medical Society and of the Ulster branch of the British Medical Association to arrange details has advised: "1. That a circular be sent to the medical men in Ulster asking them to second the efforts now being made by the medical staffs of the various charitable hospitals to diminish hospital abuse by not sending their well-to-do patients to these institutions. 2. That the medical staffs of the clinical hospitals be asked to lay before their students, as opportunity arises, the evils of hospital abuse. 3. That with regard to those who are unable to pay the full consultation fee, some arrangement between the family doctor and consultant as to modification of same should be possible. 4. That we deplore the necessity which exists of requiring '1*d.* a week' subscribers who imagine that they are paying an equivalent to treatment received. 5. That a small committee be formed to wait on the boards of management of various hospitals to explain the difficulties under which the general practitioner labours owing to hospital abuse." This report will be considered at an early of the medical profession in Belfast. Under the 1*d.* week subscription the working classes subscribed to the Royal Victoria Hospital last year a sum of £3894, and it is calculated that for this they were accommodated to the extent of about two wards, or 64 beds, but it must be recollected that quite independently of such a subscription many of those admitted by this arrangement could, as in the case of sudden and severe accidents, *ipso facto* have entered the hospital. Apart from hospital abuse there can be no doubt that the Truck Act injured general practitioners very much in Belfast, as many medical men were formerly appointed to look after various works, an arrangement which ceased when that Act was passed. Although there are not so many clubs in Belfast as in similar large centres in England there is as much sweating and while in England a medical man with a club generally attends the women and children of the members, for which he gets additional pay, in Belfast he is not at all so sure of being called in by them.

Ulster Medical Society.

A meeting of this society was held in the Medical Institute, Belfast, on April 2nd. The first business was to receive the report of the committee on hospital abuse, when it was decided to send the recommendations to each member of the society and to call a conjoint meeting of the society and of the Ulster branch of the British Medical Association to consider them in May. Dr. A. Dempsey read notes of a successful case of Cæsarean Section. Dr. J. H. McKee of Harrogate read a short paper on Harrogate and its Treatment. Dr. Cecil E. Shaw brought forward a communication, "Squint in Childhood," a paper based on over 200 cases.

Municipal Grants in Aid.

THE Municipal Council of Paris during its recent sittings has voted various grants in aid, amongst which are the following. A sum of 3000 francs to children's dispensaries for the distribution of sterilised milk. The sum of 94,000 francs in aid of children's dispensaries in general. The sum of 169,800 francs for laboratories of bacteriology and radiography, for libraries, and for travelling scholarships. A sum of 3000 francs for bringing the laboratory of neurology under the care of Professor Albarran up to date for the congress of 1908. The sum of 1000 francs towards the International Polyclinic of M. Aubeau. A sum of 141,000 francs for the foundation of an oto-rhino-laryngological department at the Laennec Hospital. Lastly, a sum of 365,000 francs for carrying out the isolation of tuberculous patients in the hospitals.

A Medical Trial.

An interesting judgment was given by the Tribunal of the Seine on March 31st. Madame X sued Professor Berger for 110,000 francs damages in regard to an operation which that surgeon had not seen fit to conclude. The operation in question was undertaken to restore the nose of the daughter of Madame X. After Professor Berger had prepared the graft, which he had taken from a costal cartilage, he saw that it would be dangerous to do any more. Madame X, without listening to the excellent reasons which Professor Berger laid before her in defence of his conduct, sued him for 100,000 francs on behalf of her daughter whom she said had been irreparably damaged by his refusal to continue the operation, and also for 10,000 francs for herself. The Tribunal appointed three experts to consider the conduct of Professor Berger; they reported that they considered that he had acted perfectly correctly and Madame X was accordingly non-suited.

A Comparison of the Diagnostic Value of Pirquet's and Calmette's Reactions.

IN Professor Monti's out-patient department, where about 30 children are seen daily for the first time and about double that number of old patients, Dr. Kremer has made a series of comparative observations in order to ascertain whether eipts apart from these fees for slaughtering were: for rent standing room 8910 marks; weighing fees, 2323 marks; rage, 24,413 marks; stables, 17,587 marks; and food served the restaurant, &c., 26 519 marks; or a total of 166,660 rks, including the pfennigs, which are not given in the ove figures. Then to this must be added, though not so ectly connected with the abattoir business, the rents paid r various parts of the premises used for a saloon where meals d refreshments are served to all who have business or rk at the abattoir, or for dwellings, drying lofts, places examining meat, hide-sheds, altogether yielding 15,018 rks. The sale of dung for manure brought in 2195 marks d sundries 1640 marks. The interest on the reserve funds s 13,668 marks; sundry fees came to 806 marks; and odds d ends, 777 marks. Loans on bonds and shares refunded 43 marks, so that the grand total receipts were 250,101 rks. Then there were money transactions not directly nnected with the abattoir costing 16,169 marks and the yment of taxes 12,092 marks; salaries, cost of supersion, printed matter, stamps, &c., 67,693 marks. The st of hay, straw, coals, light, water, repairs, cleaning, moval of confiscated carcasses, 64,368 marks; sundries, 02 marks; various purchases, 484 marks; rent for adjacent ound, 3000 marks; purchase of bonds for reserve fund, ,868 marks; cost of refunding, 4894 marks; making a tal expenditure of 244,342 marks; cash in hand, 5758 arks; total balance, 250,101 marks. From all these figures will be easy to see at what cost the public abattoir is anaged and that it can be made a paying and going concern ven in the unfavourable circumstances existing at Stuttart. The building erected by the Butchers' Union is not, of ourse, in keeping with modern exigencies, but it is, neverheless, very preferable to the private slaughter-houses hich it supplanted. Now also that it is under municipal anagement the best use is made of it and every possible recaution is taken. Of course, the animals are carefully spected by fully qualified veterinary surgeons both before nd after slaughter. For this there is one chief veterinary urgeon and six fully qualified assistants with special nowledge of bacteriology. Only veterinary surgeons work n Stuttgart, though in the outlying suburbs ordinary meat nspectors were employed. Formerly a certain amount of neat was smuggled in from the outside and was not taken o the abattoir for inspection. One of the arguments in avour of an *octroi* was that it would stop this practice. Then in 1677 the *octroi* was established a special store had o be built where all the meat from the outside was deposited or examination and the levying of the town dues. To-day here is not only very strict examination at the abattoir but nspectors must go to all the retail shops at least once a week and see that everything is thoroughly clean. Thus the xample given at Stuttgart is certainly encouraging and worth taking into consideration.

(FROM OUR OWN CORRESPONDENT.)

Annual Meeting at the General Infirmary.

THE 140th annual meeting of the supporters of the Infirmary, which is the largest general hospital in Yorkshire, was held on March 25th, under the chairmanship of the treasurer, Mr. Charles Lupton. From the report of the work accomplished during the 12 months ending Dec. 31st, 1907, it appears that 7055 patients were treated in the wards, that number including 341 patients who remained in at the end of 1906. This number was just 34 ahead of the previous year, and probably represents the maximum number of cases that can be adequately dealt with under the present conditions as to accommodation. Of the new patients admitted 1348 were medical, 4420 were surgical, and 977 were ophthalmic and aural. The daily average number of beds occupied was 363, the average number of patients passed through each occupied bed was 19·26, and the average duration of treatment of each was 19 days. It will be noticed that the last figure is low and this is due to the fact that, especially from the surgical wards, large numbers of patients who have been operated on and who require skilled nursing are transferred to the two semi-convalescent hospitals at Cookridge at an earlier date than they could be taken to their own homes or removed to convalescent hospitals which are not provided with accommodation for patients who require so much supervision. The rate of mortality was 6·65 per cent., but deducting the 140 patients who died within 48 hours of admission the percentage works out at 4·68. There were 729 cases of accident admitted; of these 68 were burns and scalds, 53 being in children and 15 in adults, and the mortality in these distressing cases was 63·23 per cent. The new out-patients amounted to 40,418. The out-patient maternity department, which provides abundant facilities for the work of the students, has been carried on in the same way as in former years, and during the year there were 502 confinements. For a good many years an inquiry officer has been employed by the infirmary who devotes all his time to making investigations as to the financial position of applicants for relief and treatment at the institution. In the waiting hall in the case of 14,447 patients inquiries were made; of these 124 admitted their ability to pay and were not attended to. A percentage of those apparently suitable for infirmary treatment was made the subject of further inquiry at the addresses given. Of 967 thus investigated 876 were deemed suitable cases and 91 were unsuitable as they were found quite able to pay for the treatment required. It is a fact which is sometimes overlooked even by those who might be supposed to know better that the number of women and children treated in the infirmary is greater than at any other special or general infirmary in Yorkshire. In the out-patient department there were 11,332 children under 13 years of age and in the in-patient department 1412 under the same age, while the total number of women treated (exclusive of those in the maternity department) was 14,858. Turning to the finances the total receipts for the year 1907 were £29,361, as against £30,814 for the previous year. Benefactions showed a diminution of £2016. The total expenditure on the three institutions—that is to say, on the General Infirmary and on the Ida and Robert Arthington Hospitals—amounted to £36,215, so the expenditure has exceeded the income by £6854. To this must be added the amount of an adverse balance at the beginning of the year, so that the debit balance now amounts to the large sum of £14,946. This disproportion between income and expenditure has been partly met by the allocation of £11,843 from the investments held by the trustees of the Leeds House of Recovery to the use of the Leeds Infirmary. The money is retained by the Charity Commissioners and the income only paid to the infirmary, but it will meet the loss of income occasioned by the loss on the year's working. The chairman made an urgent appeal for more support, pointing out that the expenses must of necessity increase. The addition of ten nurses to the staff has involved an additional annual expenditure of £600, and the sum of £688 has been expended in the alteration of houses in the possession of the infirmary to provide accommodation for these extra members of the staff. It is certain that in the immediate future additional accommodation will be required in the way of operating theatres, but this cannot be undertaken until funds are forthcoming.

April 13th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Medical Inspection of School Children in Cardiganshire.

ONE of your local correspondents referred last week to this subject briefly. The position is as follows. At the last census the population of Cardiganshire was 60,237 and since the previous census there had been a decrease of about 2500 persons. The area of the county is 440,630 acres, or about that of Worcestershire where the population is approaching 500,000. There are thus difficulties attending the medical examination of school children in Cardiganshire which are not so pronounced in more densely populated English counties, and in order to find some way of overcoming them a conference of representatives of the county education committee, the sanitary authorities, and medical officers of health was recently held in Lampeter. Two proposals were considered. One that a medical officer should be appointed for the whole county and that his duties should be confined to the medical inspection of the school children, and another that the inspection should be carried out by the medical officers of health in their respective districts. It appeared to be considered by a majority of those present that the difficulty of getting from one part of the county to another was an insuperable objection to the appointment of only one official and ultimately

Thomas's Hospitals; John Hayward Paget, Charing Cross Hospital; Michael William Phipps, Queen's College, Cork, and London Hospital; Edward Philip Stibbe, Charing Cross Hospital; and Harold Skarratt Thomas, London Hospital and private.

At the second professional examination in Anatomy and Physiology held on March 26th, 27th, 30th, and 31st, 98 candidates presented themselves for examination, of whom 53 were approved and 45 were rejected. The following are the names of the successful candidates:—

Harold George Alexander, Middlesex Hospital; Sydney Vere Appleyard, St. Thomas's Hospital; Malcolm Barker, Charing Cross Hospital; Thomas Mulholland Bellew, Liverpool University; Jamshedji Sorabji Bhajiwalla, Bombay University, Middlesex and University College Hospitals; Arthur Brodie Hamilton Bridges, St. Thomas's Hospital; William Edgar Carter, Leeds University; Eric Edmund Chipp, St. Bartholomew's Hospital; Reginald Charles Clifford, St. Bartholomew's Hospital; Reginald Manchester University; Ellis Patrick Crozier, Ceylon Medical College and London Hospital; George Leslie Curnock, Charing Cross Hospital; Hubert Daw, Guy's Hospital; Arthur William Donaldson, Oxford University; William Alexander Dunn, Otago University and St. Thomas's Hospital; William Halley Eggar, Middlesex Hospital; Daniel Charles Evans, University College, Cardiff; Montague Albert Farr, Charing Cross Hospital; George Herbert Garlick, St. Mary's Hospital; Douglas Hamilton, King's College Hospital; Charles Herbert Hart, University College, Bristol; Henry Edwardes Griffiths, University College, Cardiff; George Holmes-Smith, L.D.S. Eng., King's College; William Henry Talfourd Jones, Guy's and King's College Hospitals; George Arthur Edward Kelman, Westminster Hospital; William Bertram Lawrence, University College, Cardiff; Tam Legge, Madras and London Hospital; Wilfred Edgar Levinson, Guy's Hospital; Edward Claude Linton, London Hospital; Bryen McDermott, Guy's Hospital; Reginald Kinloch MacGregor, St. Bartholomew's Hospital; Horace Lloyd Mann, St. Thomas's Hospital; Patrick John Monaghan, Guy's Hospital; Hubert Lewis Clifford Noel, London Hospital; Henry Clarence Wardleworth Nuttall, Liverpool University; Thaddeus Turner O'Callaghan, Guy's Hospital; John Francis O'Malley, L.R.C.P. & S. Irel., L.M. Dub., Dublin and King's College; William Howard Pickup, Birmingham University; Charles Edward Reckitt, Guy's Hospital; Edward Smeed, University College Hospital; Reginald Gershom Sparkes, St. Mary's Hospital; Alan Murray Stuart, St. Mary's Hospital; Richard Teodor Timberg, St. Thomas's Hospital; John Saint Andrew Titmas, L.D.S. Eng., Middlesex Hospital; John John Tozer, St. Mary's Hospital; John William Trevan, St. Bartholomew's Hospital; Arthur George Trott, Charing Cross Hospital; Percival Dillon Warburton, Sheffield University; Archibald Farrell Waterhouse, Sheffield University; Harvey Henry Vincent Welch, St. Thomas's Hospital; Herbert White, St. Thomas's Hospital; Walter George Wince, L.M. & S. Calcutta, Calcutta University and St. Bartholomew's Hospital; and Walter Ansley Young, Madras Medical College and London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the ordinary Council meeting held on April 9th the following diplomas were conferred upon the undermentioned gentlemen who have passed the necessary examinations and have now complied with the by-laws of the College:—

Diploma of Fellow.—Joseph Bernard Dawson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Birmingham University.
Diploma of Member.—Kenneth Douglas Panton, M.B. Toronto, Toronto University and London Hospital; Robert Kerr Paterson, M.D., C.M. Kingston, Queen's University, Canada, and London Hospital; and George Charles Edward Simpson, B.C. Cantab., Cambridge University and St. Bartholomew's Hospital.
Licence in Dental Surgery.—Andrew Robertson Walker, D.D.S. Pennsylvania, Pennsylvania University.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination held recently the following candidates passed in the subjects indicated:—

PART I.

Biology—R. B. F. Frazer, Charing Cross Hospital; R. H. Pettersson, Birkbeck College; and S. J. S. Reid, Royal Free Hospital.
Chemistry.—R. B. F. Frazer, Charing Cross Hospital; and S. J. S. Reid, Royal Free Hospital.
Materia Medica and Pharmacy.—E. Carter, Durham; H. R. Coombes, Cambridge and Westminster Hospital; F. C. Eberhardt, Edinburgh and Birmingham; and J. McManus, Belfast.

PART II.

Anatomy.—G. S. Bate and J. A. A. Boddy, Manchester; C. S. Foster, Westminster Hospital; E. A. S. Hoare, Charing Cross Hospital; A. J. V. Mathews, St. Mary's Hospital; and J. G. Reidy, Edinburgh.
Physiology.—G. S. Bate and J. A. A. Boddy, Manchester; J. Brearley, Leeds; P. Hirschbein, Guy's Hospital; E. A. S. Hoare, Charing Cross Hospital; J. B. Holmes, Manchester; J. G. Reidy, Edinburgh; W. G. Tickell, Middlesex Hospital; and C. B. Welsby, London Hospital.

UNIVERSITY OF DURHAM.—At the convocation held on April 4th the following degrees and diploma were conferred:—

Doctor in Medicine.—James Glenny Gibb, M.B., B.S. Durh.; Sampson George Victor Harris, M.B., B.S. Durh.; Arthur Holbrook Nott, M.B. Durh. (*in absentiâ*); John Cuthbert Pearce, M.B., B.S. Durh.; William Tait Sewell, M.B., B.S. Durh.; and Edward Tate, M.B., B.S. Durh.
Doctor in Medicine for Practitioners of 15 years' standing.—David Donald, L.R.C.P.&S., L.F.P.S. Glasg.; Benjamin William Nettlefold Gowring, M.R.C.S., L.R.C.P.; Robert Hudson, L.M.R.C.P.&S. Irel.; Walter Wingfield Nuttall, M.R.C.S., L.R.C.P.; and Robert George Reid, L.R.C.P. & S., L.F.P.S. Glasg.
Master in Surgery (M.S.).—James Glenny Gibb, M.B., B.S. Durh., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.
Bachelor in Medicine (M.B.).—Ronald Martyn Davies, Helen Mary Gurney, Arthur Henry Hogg, Ernest Lacey Markham, and Gertrude Ethel O'Brien, College of Medicine, Newcastle-upon-Tyne; Charlotte Purnell and Elizabeth Patteson, London School Medicine for Women; Hubert Shield, College of Medic Newcastle-upon-Tyne; Eric Frushard Waddington, University Leeds; Leslie Henry Walker and James Burrell Williams College of Medicine, Newcastle-upon-Tyne; and John Frankl Young, Guy's Hospital.
Bachelor in Surgery (B.S.).—Ronald Martyn Davies, Helen Ma Gurney, Arthur Henry Hogg, Ernest Lacey Markham, a Gertrude Ethel O'Brien, College of Medicine, Newcastle-upon Tyne; Charlotte Purnell and Elizabeth Patteson, London School of Medicine for Women; Hubert Shield, College of Medicine, Newcastle-upon-Tyne; Eric Frushard Waddington, University of Leeds; Leslie Henry Walker and James Burrell Williamson, College of Medicine, Newcastle-upon-Tyne; and John Franklin Young, Guy's Hospital.
Bachelor in Hygiene (B.Hy.).—Robert Samuel Trotter, M.D. Aberd.
Diploma in Public Health (D.P.H.).—Samuel Thomas Cochrane, M.B., B.S. Durh.; Lilian Mary Chesney, M.B., Ch.B. Edin.; Edward Guy Dru Drury, M.D., B.S. Lond.; George Pillans Harlan, M.D., Ch.B. Glasg.; and Robert Samuel Trotter, M.D. Aberd.

UNIVERSITY OF ABERDEEN.—The following degrees were recently conferred:—

Doctor of Science (D.Sc.).—John Wishart.
Bachelor of Science (B.Sc.).—Christian Davidson Maitland, James Fowler Tocher, Charles Cumming Calder, James Graham Darling, and Hugh Sinclair Robertson.
Doctor of Medicine (M.D.).—William Flett Croll, William Sim Garden, James Robertson, and Lieutenant-Colonel Henry Thomson.
Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—With First-class Honours: James Watt. With Second class Honours: Thomas Craig Boyd. Ordinary Degree: John Anderson, Alex. Andrew Bisset, John Brown, Donald Buchanan, James Barr Cruickshank, James Gordon Danson, George Davidson, Adam Gilchrist, James Alexander Hendry, M.A., B.Sc., Edward Johnson, James William Littlejohn, William George Macdonald, James Davidson Mackay, John Farquhar Macleod, Rae McRae, Allan Massey, William Mearns, Arthur James Milne, Thomas Burtonshaw Nicholls, Ian Ogilvie, Arthur William Rettie Pirie, Douglas Porter, John Rennie, Robert Ross, Andrew James Shinnie, William Alexander Watson, William Gordon Watt, Maurice Joseph Williamson, and Douglas Wood.

The following gentlemen have been awarded the *Diploma in Public Health*:—

William Begg, M.B., Ch.B. Aberd., John Hay Moir, M.B., Ch.B. Aberd., and George Scott, M.B., C.M. Aberd.

THE CENTRAL MIDWIVES BOARD.—At a meeting of the Central Midwives Board held at Caxton House, Westminster, on April 9th, Dr. F. H. Champneys was re-elected chairman and received the thanks of the Board, expressed by Mr. E. Parker Young, who said that the Board wished to recognise their appreciation of Dr. Champneys's work by re-electing him to the office of chairman. Mr. H. G. Fordham was re-elected honorary treasurer. The action to be taken on the Board's resolution of March 19th as to the payment of fees of medical practitioners summoned to assist midwives in emergencies was considered and the Board decided:—

1. That the Privy Council be asked to furnish the Board with a return showing the boards of guardians which have adopted the suggestions of the Local Government Board as to the payment of medical fees contained in the Circular of July 29th, 1907.
2. That it be referred to a meeting of the Standing Committee to frame a statement on the subject to be submitted to the Privy Council.
3. That when the return has been furnished the Privy Council be asked to receive a deputation of the Board (*a*) on the subject of the payment of the fees of medical practitioners summoned to assist midwives in emergencies, and (*b*) concerning the following propositions affirmed by the Board on March 19th: (1) That midwives (who are "a necessity") will be unable to make a living in many localities without extraneous aid; (2) that such localities are very often exactly those in which their presence is most necessary from the poverty and (in some cases) the sparseness of the population; (3) that voluntary contributions cannot be relied upon to supply the whole of the necessary financial aid; and (4) that for this purpose a Government grant is a necessity.

Letters were then considered from the medical secretary of the British Medical Association as to the statement in the Board's letter to the Privy Council of Feb. 15th referring to the hostility existing in some districts between the medical profession and midwives. The Board decided that the reply be that the statement referred to was founded on communications to the Board, on communications which have appeared in the *British Medical Journal* and Supplement thereof, in the medical and nursing press in general, and on facts within the knowledge of members of the Board. At the request of Mr. Parker Young the report of Miss F. M. Bernard-Boyce, inspector and superintendent of midwives for the county of Norfolk, was read from the issue of the *Eastern Daily Press* dated April 2nd, licial decision in the English King's Bench was said by law agent to make that subletting illegal. The point has, wever, been contested; and no action has been taken by public health committee so that the report before me nks that "they may find themselves later on held accounte for their inaction." 3. A better defined grievance is luded in the fact that "although several Royal Commis ns have urged the advisability of having all animals ttle, sheep, and pigs) slaughtered in public abattoirs, Department of Agriculture and Technical Instruction, in te of the corporation's protest, continue to cause pigs ilt with under the swine fever order to be slaughtered a private slaughter-house situate in a district where the pulation is very congested." The authors of the report nsider that if this procedure is persisted in "the matter ould be brought under the notice of Parliament by one of Members for the city." There is no doubt that, in any ent, the inevitable prominence which will be given to the estion of slaughter-houses, and their claims and uses, will nd to keep all such establishments all the more free from order—tangible, visible, or odorous.

Royal Victoria Eye and Ear Hospital, Dublin.

At the annual meeting of the friends and supporters of the yal Victoria Eye and Ear Hospital held recently the port of the council for 1907 showed that 1369 patients om all parts of Ireland were admitted to beds in the spital during the past year. The average period of atment of these was about three weeks. An average mber of 76 beds had been occupied throughout the year. e total aggregate of hospital residence exceeded by 2000 ys that of the record of 1906 and would have been eater but for the successive closing of wards while in the nds of painters. In the out-patient department 7267 new tients were registered, while 2816 patients returned who d been formerly treated, making a total extern attendance 10,083 for the year. The aggregate number of visits of ese patients was 41,167, which shows an average of 135·4 tern patients attended to by the surgical staff daily. Many f these were children, including infants of two and three onths; and a great number of parents had written to xpress their gratitude for the attention and benefits eceived, with appreciation of the arrangements for comforts nd general convenience. The previous annual report had entioned the consideration of plans for the erection of a pecial detached building for accommodation of the treatent of extern patients. The plans are now prepared and enders for the erection obtained. An increase of funds will e necessary to defray the cost of the building. Depreciaion of securities since the former report has lowered the alue of the investments which had been made for building purposes. This amounted on Dec. 31st, 1907, to £3852 only, or about one-third of the amount required for the erection and the equipment of the building. The council accordingly earnestly asks for special donations to the building fund for this erection. The income of the institution during the past year displayed an encouraging increase on that of 1906, amounting to £716, of which £473 came in the form of bequests and £212 as voluntary contributions. This item of the financial report is considered by the council to be highly satisfactory; but against it was the cost of painting (between £900 and £1000) which had to be provided. A portion of this considerable sum is chargeable to revenue and another part to capital; a portion has already been paid, but as the work was finished but a few weeks ago a considerable proportion of the expense necessarily passes into the accounts of this year. The necessity for meeting the additional strain of this item resulted in an excess of expenditure over income for the year which has just been concluded amounting to £80. The income from bequests would have been much greater but for the depreciation of the value of securities which had taken place and which caused a complete loss to the hospital of one bequest of £2000 which would have otherwise passed into its funds.

Medical Contracts for Unions and Dispensaries.

Politics always get into Irish affairs. The following communication has been sent by the Local Government Board of Ireland to certain boards of guardians which had expressed their desire of limiting their attention to the tenders for drugs and other medical and surgical necessaries to those offered by Irish firms:—

> SIR,—The attention of the Local Government Board has been drawn to the advertisement issued by the Board of Guardians of —— Union, inviting tenders for the supply of medicines and medical and surgical appliances to the workhouse and dispensary districts of the union for the year commencing on the 1st prox., in which it is stated that tenders will be only considered from Irish firms. In reference thereto the Local Government Board have to point out that one-half of the expenditure is recouped to the union out of the Local Taxation (Ireland) Account in respect of drugs or appliances procured under prescribed conditions; and they desire to explain that unless the competition for the contracts be thrown open, so as to enable the guardians to obtain the best drugs and appliances in the market on the most advantageous terms, the Board would feel precluded from recouping from public funds any portion of the expenditure incurred in such restricted contracts.

It is impossible not to sympathise with the patriotism of the guardians and with the economy of the Government department.

Country Life for Pauper Children.

Mrs. J. Wyse Power, one of the most practical as well as devoted of Irish philanthropists, and the wife of a leading journalist, has for some years been a member of the board of guardians of the North Dublin Union. This lady has been largely instrumental in inducing her board to try the experiment of boarding out the workhouse children. Taking their stand on the fact that from every point of view, moral, physical, and mental, it is better for a child who must be put on the rates to be reared in a healthy, decent country home than in a workhouse however well conducted, Mrs. Power and her colleagues arranged in the first place to send early in 1905 27 children to Piercestown, where arrangements had been made by the parish priest to receive them. Tinahely parish received 16 on May 26th, 1906; Killinick, 17 on July 29th, 1907; and Lucan two instalments on Nov. 22nd, 1906, and April 26th, 1907, making a total of 37. And on March 10th of this year 21 were sent to Gorey. So there are now 118 children boarding out beyond the confines of the union and 127 others in North County Dublin. Mrs. Power has now discussed the results in the *Freeman's Journal* and there is surely reason to feel proud of the record. Not one of the children has died; they are all practically members of the families in which they have been placed; "and they have," she says, "the same prospects of growing up to be industrious, self-respecting, and useful members of the community, as have the children of their foster parents." She contrasts this state of things with the training afforded by the union life and its schools in the following words: "Life in the institution over, they are sent out to face the world without any experience where they must do everything for themselves and where incapacity to fight their own battle against all odds inevitably means failure and its consequences. No wonder that the results are what we know them to be and that the prison cell and the able-bodied workhouse ward—especially in the female divisions—are occupied by so many pauper-reared children grown to maturity." The economics of the experiment seem to be correspondingly encouraging. Mrs. Power tells us that although figures are not available the cost of the maintenance of the boarded-out child is actually less than if he or she had been kept within the precincts of the workhouse.

Housing of the Dublin Poor.

In an article recently published in the Dublin evening papers by Mr. T. J. Stafford, F.R.C.S.I., and Mr. La Touche, full prominence was given to the gruesome conditions of the homes of the working-classes. Not more than 12 per cent. were found to have "housing accommodation which could be regarded as satisfactory in respect of air space, sanitation, or cleanliness, and almost 60 per cent. of them lived in one room each." And the average number of the individual families caged in such rooms was five. At the corporation meeting of April 14th Mr. Lorcan Sherlock successfully moved:—

> That a special committee be now formed to inquire into, and report to council upon, the housing conditions of the workers of Dublin; that the committee report as to what action, if any, should be taken to give effect to the recommendations of the Mansion House Conference Report; that the committee be empowered to obtain legal opinion as to the powers at present possessed by the corporation and obtain information as to powers possessed by local authorities in Belfast and the large cities of England and Scotland; that the committee be requested to make suggestions which will tend to end the discreditable and dangerous condition of housing at present existing in Dublin under which over 20,000 families live in one room each.

The subject has also been brought before the corporation by Dr. J. C. McWalter and there is anticipation that measures will be taken.

Anthrax in Belfast.

A man suffering from anthrax was admitted into the Royal Victoria Hospital on April 10th. The black, dry, depressed eschar on the forehead, surrounded by a slightly elevated art is fostered and the workshops and factories, so that they may "feed" each other and support each other in the education and utilisation of industrial artists. In respect of buildings and material with the object of practical art Berlin was considered to hold the lead, but was followed closely by other continental cities. The committee also states that "Doctors, who need drawing for purposes of demonstration, and lawyers, who not only have to understand its common uses in the trades but may be called upon to judge and plead in matters affecting the Fine Arts, are for the most part unprepared for these duties." Local exhibitions in preparation for the congress are now being held or organised throughout the country. The offices of the committee are at 151, Cannon-street, London, E.C.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of the directors of the above society was held on April 8th at 11, Chandos-street, Cavendish-square, W., Dr. G. F. Blandford, the President, being in the chair. 16 directors were present. Five new members were elected and the death of one was reported. Since the last court two widows, annuitants of the charity, had died. One had been on the funds since 1873 and had received in grants £1500; her husband had paid in subscriptions £19 19*s.* The other had been in receipt of grants since 1905 and had received £205; her husband had paid in subscriptions £52 10*s.* A letter of condolence was sent to Lady Agnes Cooper on the death of her husband, Sir Alfred Cooper, who had been a director of the society. The report and audited accounts of the society for 1907 to be submitted at the annual general meeting were approved. The secretary reported that he had since the last court received eight letters from widows of medical men asking for relief, but this had in each instance to be refused, as their husbands had not been members of the society. Relief is only granted to the widows or orphans of deceased members. Any registered medical practitioner who at the time of his election is residing within a 20-mile radius of Charing Cross is eligible for membership. The subscription is £2 2*s.* a year, paid in one sum or in two half-yearly ones of £1 1*s.* each. Full particulars may be obtained from the secretary. The invested funds of the society amount to over £99,000. The annual general meeting will be held on May 14th, at 5 P.M., at the offices of the society.

The New Manchester Infirmary.—An important meeting of the people of Manchester and the surrounding districts convened by the Lord Mayor of Manchester was held on April 7th in the town-hall for the purpose of considering the present financial condition and the future requirements of the new infirmary. The estimated expenditure on the new building in Oxford-road and on the provision of a central branch is £525,000, towards which there is a sum available of £425,000, including the £400,000 from the corporation, the purchase price of the old infirmary, so that £100,000 to complete the undertaking must be raised. The estimated cost of maintenance is £34,500, while the available income is £22 500, leaving a further annual sum of £12,000 to be provided. This looks a formidable undertaking but the Lord Mayor has attacked it with courage. The accommodation at the old infirmary was limited to 292 beds and so could not do nearly the amount of work required of it. The Lord Mayor said that he approved of the erection of the present building, for it would not have been wise to build an infirmary too small for present requirements. He saw no signs of extravagance in the new building itself and the money had been so spent "that 20*s.* had never been spent where 19*s.* would have done." He reminded the meeting that the infirmary had claims on the whole of Lancashire, Cheshire, South Yorkshire, and Derbyshire and concluded by proposing a motion expressing the sense of the meeting of the value of the services of the infirmary for a century and a half to the sick poor of Manchester and the neighbouring counties. The Bishop of Manchester followed with a strong and logical speech in support of the view expressed by the Lord Mayor, that the strongest though perhaps the lowest of all sentiments, that of self-interest, commended work like that of the infirmary to support. It benefited not only the poor but the wealthy. Other speakers followed and at the close of the meeting it was announced that considerably over £24,000, including amounts promised during its course, had been the response, so far, to the special appeal. The Lord Mayor thought it an exceedingly good start that s much had been raised before a general appeal to the publi had been made. It is to be hoped that the response w come largely from those who cannot give large sums and ye do not wish to be deterred from giving what they can. A the Bishop said, he could not, out of the "fatal opulence" o a Bishop, promise anything like £1000, but he would do all he possibly could for their great cause.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Progress of Legislation

Nearly 200 Bills have been introduced in the House of Comm since the meeting of Parliament in the end of January, but comparatively few of them have yet received a second reading. Several measures, including the Children's Bill with its provisions direc against juvenile smoking, have reached the committee stage. Mr. Higham's Coroners' Inquests Bill is also before a standing committee. Several unsuccessful attempts have been made by Sir John Batty Tuk and those associated with him to induce the House to assent to the second reading of the Prohibition of Medical Practice by Companies Bill after 11 o'clock at night. Objection has invariably been raised, the consequence of which at such an hour is to delay the progress of the Bill. Amongst the measures which are now on the notice paper of the House awaiting second reading are the Coroners' Inquests (Railway Fatalities) Bill, the Housing and Town Planning Bill, the Nurses Registration Bill (Mr. Claude Hay's measure), the Nurses Registration (No. 2) Bill (Mr. Munro Ferguson's measure), the Parochial Medical Officers (Scotland) Bill, the Pharmacy Bill, the Public Health Bill (Mr. G. J. Cooper's measure), the Publ Health Officers Bill, the Purity of Milk-Supplies (Scotland) Bill, the Sale of Food and Drugs Acts (Amendment) (Scotland) Bill, the Sale o Whisky Bill, and the Vivisection Bill.

In the House of Lords the number of Bills introduced is far less than in the Commons. One measure which their lordships have read a second time is the Poisons and Pharmacy Bill. A joint committee o both Houses of Parliament is engaged in taking evidence on the point raised in it.

Inspection of Factories and Workshops.

The supplement to the annual report of the Chief Inspector o Factories and Workshops for the year 1906, which has just been issue as a Parliamentary paper, is rather belated, but it gives statistic information with regard to the work carried out by medical officers o health in this period under the Factory and Workshop Acts. It i stated that 1855 reports of medical officers of health were due to b received from England and Wales for the year 1906 but only 1811 came to hand at the Home Office. From Scotland 325 reports were due to b received and of them 322 actually were received. For Ireland 72 reports were due but only 303 actually came to hand. The number o inspections made by medical officers of health during the year i pursuance of their duties with regard to factories, workshops, an workplaces is set down as 459,856 for the United Kingdom. It i recorded that 373,116 were made in England and Wales, 70,418 i Scotland, and 16,322 in Ireland.

The Reconstructed Ministry.

The resignation of Sir Henry Campbell-Bannerman of the post o Prime Minister and the reconstruction of the Ministry unde the leadership of Mr. Asquith have brought about several im portant changes in the Government. Mr. Lloyd George becom Chancellor of the Exchequer and Mr. Churchill succeeds hi as President of the Board of Trade. Lord Tweedmouth takes th position of Lord President of the Council and Mr. McKenna is th new First Lord of the Admiralty, whilst Mr. Runciman succeed him as Minister for Education. The Earl of Crewe takes up the duti of Colonial Secretary, with Colonel Seely in the House of Commo as his under-secretary. Mr. Gladstone remains as Home Secretar with Mr. Herbert Samuel as the under-secretary. Mr. Bur continues as President of the Local Government Board a Mr. Masterman takes the office of Parliamentary Secretary this department in place of Mr. Macnamara, who is now Secretary the Admiralty. There are a few other changes, but the ones enumerat are the most important. Medical men will be interested in the elevati of the position of the President of the Local Government Board to fir class official rank, as evidenced by the proposed increase of salary, the State Medicine of the country is administered in this department.

Easter Vacation.

The House of Commons met on Tuesday in order that the writs f the elections necessitated by the Cabinet changes might be ordere There were a large number of questions on the notice paper, includi one or two of medical interest, but these were not answered. T House adjourned until Monday, April 27th.

almette's and Pirquet's reactions were of equivalent value not. He divided the individuals into three distinct oups—namely, cases of tuberculosis with positive clinical mptoms, cases of suspected tuberculosis, and non-berculous cases. In each group the observations were ade at the same time. The first group consisted of 33 cases, whom 17 were treated by Pirquet's method of cutaneous oculation with tuberculin and 16 were treated by Calmette's ethod of instillation of a drop of a solution of tuberculin of per cent. into the conjunctival sac. Pirquet's method gave positive and two negative results while Calmette's method ave 12 positive and four negative results. The patients cluded cases of meningitis, peritonitis, lupus, cold abscess, aries of bone, pulmonary tuberculosis, and lymphoma of the eck. The last-named cases gave negative results by Pirquet's ethod whilst Calmette's method failed to produce any action in these as well as in the cases of lupus and caries of one. The second group consisted of 35 cases, 18 of which ere treated by Pirquet's method with 15 positive results, hilst 17 were treated by Calmette's method with 12 positive sults. The patients comprised cases of bronchitis, pleuritis, næmia, and catarrhal disease of the lungs. The third roup consisted of 25 cases free from any suspicion of uberculosis. Of this group 14 patients were treated by irquet's method with four positive results whilst 11 were eated by Calmette's method with two positive results. r. Kremer took care to select cases as much as possible imilar to each other for the control tests. Wherever ossible both tests were used in the same individual at the ame time. Pirquet's reaction sometimes showed itself five ours after the inoculation but as a rule, the effect was roduced in 24 hours and lasted from four to six days. Once t was visible for 11 days. Calmette's reaction occurred, as rule, six hours after application but in one instance only After 24 hours; it lasted mostly from four to five days but n two instances for eight and 12 days respectively. In five ases the cutaneous reaction was positive whilst the ocular reaction failed to show the presence of tuberculous disease, and in four cases the eye was severely affected for some days. Dr. Kremer therefore concludes that of the two methods the cutaneous one is the more trustworthy, the easier, the less severe, and the less painful.

Legislation Concerning Phosphorus Poisoning.

The efforts of the sanitary and health departments with regard to the inspection of factories have resulted in the issuing by the Government of new regulations for the manufacture of matches and other articles in which the poisonous yellow phosphorus is used. The following points are worth mentioning. No person under 17 years of age and no woman who is either more than four months pregnant or has been confined within the preceding six weeks may be employed on the premises. The workers must be employed by turns in the different departments, being engaged in each for only four weeks, so that they do not come in contact with the phosphorus emanations oftener than every three months. Special attention is paid to ventilation and the regulations require it to be inspected daily. The premises where articles manufactured with phosphorus are stored must be provided with double doors and the persons engaged there must also change their occupation every few weeks. The factory workers must have special prophylactic and hygienic facilities. They must, for instance, have suits of working clothes with sleeves fitting closely at the wrist; ablution rooms and mouth-rinsing utensils must also be provided by the owner of the factory, their teeth must be regularly inspected, and a first-aid box containing antidotes must always be at hand.

Osteomalacia and Adrenalin.

An interesting discussion took place recently at a meeting of the Lemberg Medical Society when several cases of osteomalacia were exhibited. Dr. Groebel showed a woman aged 40 years who had been confined to bed since her last labour six years ago because she had pain in her bones and could not walk. The measurements of the pelvis and other bones had not changed during treatment, which consisted of daily injections of adrenalin in increasing doses, beginning with half a cubic centimetre (eight minims) of a solution of strength 1 in 1000. The result of 25 injections was very satisfactory as the patient could walk about without experiencing any unpleasant sensations. In addition to this example of chronic osteomalacia another patient was shown suffering from the acute type; she also was unable to walk and could hardly move her lower limbs. Tenderness on pressure was present and a marked feature was that all the long bones and the ribs could be bent on pressure. When she first came under observation she was seven months pregnant. Following Bossi's suggestion she was at once treated with one daily injection of one cubic centimetre of a solution of adrenalin of strength 1 in 10,000. During the first four days headache, high blood pressure, and a red hue of the face were noticed, but after the first week these effects disappeared until an increased dose was given which always caused unpleasant symptoms. Altogether 54 injections were given, with the result that the pains disappeared, the bones became hard, and the pelvis did not change its shape. In the discussion it was maintained that different observers had obtained different results, perhaps on account of using adrenalin obtained from different manufacturers. The danger of the indiscriminate use of this substance was pointed out, as in some animals, especially rabbits, arterio-sclerosis could be produced by injections of adrenalin. The use of phosphorus and salts of lime was recommended for the treatment of osteomalacia. This disease was said to be very rare in some countries and to be most often met with in marshy districts.

Congress on Thalassotherapy.

The Fourth International Congress on Thalassotherapy will be held at Abbazia on the Austrian coast of the Adriatic sea. The therapeutic use of natural mineral waters will be included among the subjects and the discussions will deal not only with the treatment of disease by sea air, sea water, and sea voyages but with hydrotherapy and balneological questions. The congress will meet from Sept. 28th to 30th and will no doubt attract many medical men from the Riviera, from Italy, and from the Netherlands.

Surgery of the Lungs.

At a recent meeting of the Brünner Medical Society Dr. Herzka gave an interesting synopsis of the present condition of the surgery of the lungs. He said that the prevalent idea that pneumothorax must be avoided was the chief obstacle to the development of this branch of surgery. Sauerbruch's low-pressure apparatus, Brauer's high-pressure apparatus, and Kühn's method of producing high pressure by per-oral tubage had now made the way for the surgeon an easy one, but all these methods were too complicated for ordinary operators. The same object was attained by suturing the costal and pulmonary pleuræ together. The principal danger of pneumothorax was the sudden change of blood pressure in the lesser circulation and not the diminution of the respiratory surface of the lung. The most favourable results were obtained in operations on gangrenous cavities or abscesses of the lung. For the cavities of bronchiectasis the prognosis was worse and those associated with tuberculosis were unsuitable for operation. Tumours had not often been treated surgically as the diagnosis was difficult and the prognosis was doubtful. The production of pneumothorax for the treatment of pulmonary tuberculosis had been advised by Murphy and practised sometimes with injection of nitrogen rather than of air, because the latter was absorbed too quickly. The method was useful only in unilateral cases. The latest development in this direction had been achieved by Trendelenburg who attacked a thrombus of the pulmonary artery artificially produced in a calf and succeeded in saving the animal's life.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy of the Conjoint Examining Board held this month the following gentlemen were approved :—

Henry Bardsley, Liverpool University; John James Harkness Beckton, St. Bartholomew's Hospital; Alfred William Beris, St. Mary's Hospital and private; Henry Dyer Scott Close, St. Thomas's Hospital; William Russell Cooper, University College; Reginald Branch Dawson, Guy's Hospital; Frederick Dunphy, Westminster Hospital and private; Frank Austin French, St. Mary's Hospital; Herbert Wilks Heasman, Guy's Hospital; John Keith Anderton Helm, Guy's Hospital; Joseph Arthur Alexander Kernahan, St. Bartholomew's Hospital; Bhagat Ram Khanna, London Hospital and private; Robert Lloyd, Sheffield University and private; Richard Turner MacRae, London Hospital; Valentine Cave Martyn, St. Mary's Hospital and private; Percy Uredale Mawer, St. Bartholomew's Hospital; Reginald Arthur Morrell, St. Thomas's Hospital; Michael Wellwood Morrison, Bristol, Middlesex, and St.

Notes, Short Comments, and Answers to Correspondents.

CHAMPAGNE AT 1s. PER PINT BOTTLE.

AT Bow-street police court recently George Henry Kemp was summoned for selling at an address in High Holborn foreign wine without a licence and also with selling "sweets" and "made wines" without a licence. The defendant pleaded guilty and the explanation was offered on his behalf that he was duly licensed to manufacture British wines and to sell foreign wines at Walthamstow and that he thought that the latter licence covered sales made at his address in High Holborn. He was fined £20 with 2s. costs. Incidentally to the prosecution for selling without a licence it was proved that the attention of the Inland Revenue authorities had been attracted by advertisements in the newspapers offering champagne at 1s. per pint bottle and representing that the wine was made in England from imported grapes under Government supervision. It was explained that the Commissioners of Inland Revenue repudiated the last statement, as they exercised no supervision over any such manufacture, but it may be suggested that the licence under which the wine was produced and which probably prompted the vendor to claim some sort of Government authority for its production has a parallel in the stamp which is placed on "patent medicines" for revenue purposes and which, as is well known, deceives ignorant people into a belief that such *nostrums* are compounded under the direct authority of the Government. In the case in question the description of the wine as "champagne" constituted it a foreign wine for the purpose of the prosecution. "Champagne" indicates a country of origin, just as the name "port" is properly applicable only to the wine made in a certain district of Portugal and shipped from Oporto. Possibly a qualifying statement such as that made in the advertisement mentioned above to the effect that the "champagne" sold in High Holborn was made in England may protect the seller of "sweets" (as such wines are called technically) from legal proceedings of the kind taken with regard to "port" from Spain and mentioned recently in THE LANCET (March 21st, p. 907), but it is worth noticing that wine called "champagne" and sold in bottles made up to resemble bottles containing champagne can be made, advertised, and sold at the modest price of 1s. per pint, and it may be suggested that any use of the term "champagne" on what is apparently a champagne bottle may deceive ignorant purchasers as to the nature and quality of what they are obtaining. The matter is of some interest to medical men who on occasions may order champagne to be drunk by persons not able to afford high prices, or may permit it to be drunk, or may be called upon to treat persons who have drunk it.

LONGEVITY AT BRIGHTON.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 4th, p. 1041, I see you have a note on longevity and you make mention of Jeremiah Simmons, who is a most remarkable man for his years. On the day he reached centenarianism he was up and dressed by 8 o'clock in the morning, shaved himself (as he does daily), read his paper without spectacles (he has never worn glasses of any kind), signed his name at least 50 times, received dozens of visitors, went to bed at 9.30, and told me that it was one of the happiest days of his life and that he felt no fatigue from the excitement of the day.

I have been taking notes recently at Brighton respecting longevity, because there can be no doubt that the splendid air of Brighton is conducive to longevity, and also because I notice that men of 80 years of age (whom I have known since I was a boy) are still pursuing their ordinary avocations, strong, vigorous, and energetic. Only last week an old person (Mrs. Baker) died there in her ninety-ninth year and her faculties were unimpaired to the end. Since 1900 the following centenarians have died at Brighton, the majority of whom had been lifelong residents:—Charles Green, 101 years; Miss Shergold, 105 years; Mrs. Walter Cobbold, 100 years; Miss Margaret Baker, 100 years; Mrs. Fairman, 100 years; Surgeon-Major Bowron, 101 years; Mrs. Colwell, 101 years and seven months; Mrs. Priestley, 100 years; Captain W. Sitwell, 100 years (all but ten weeks); and Mrs. Harbor, 100 years. I know of three men aged 98 years and four women 98, 97 (two), and 96 still living there, and old John Sorrell, 96 years of age, walked a mile in the rain last December to receive a poor-box bounty. I believe no other town can show similar figures.

I am, Sir, yours faithfully,
J. P. BACON-PHILLIPS.

Crowhurst Rectory, Sussex, April 10th, 1908.

ROYAL HOSPITAL FOR INCURABLES, DONNYBROOK: A CURIOUS CASE.

A REMARKABLE object-lesson was given to the public by the result of an inquiry held at the Royal Hospital for Incurables, Donnybrook (Dublin), as to the circumstances attending the death of an inmate, which took place on April 11th. On the morning of that day the medical officer of the institution had his attention arrested by finding the deceased man in a deep sleep, which was unusual, as he was in a very emaciated and restless, as well as hopeless, condition. He was awakened by the medical officer who asked him whether he had taken any soporific. He denied having done so, but on searching the bed a bottle of chlorodyne and some five-grain tabloids of sulphonal were discovered. On being asked how these came into his possession he said that they had been given by a lady visitor. This statement was promptly denied by the lady named when inquiry was made and no further information on that head could be obtained. The patient died at 6 P.M., the medical officer stating that the drugs hastened death but a very short time. Death was attributed by the medical officer to "cardiac failure, accelerated by the action of drugs." The coroner expressed the hope—with regard to bringing in the drugs—"that whoever has done this will if it reaches their ears be warned for all time against doing such a thing." The jury found a verdict in accordance with the medical evidence, adding: "We desire to condemn in the strongest way the practice of any visitor introducing drugs or other medicines into the hospital without the knowledge of the medical staff, and we further desire to place on record our appreciation of the skill and care bestowed by the medical staff of the institution in their treatment of the patients."

JORDAN WATER.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me where I can procure a small quantity of Jordan water for baptismal purposes?

I am, Sir, yours faithfully,
A. B. C.

April 7th, 1908.

"WOLSEY" UNDERWEAR.

WE have received from Messrs. R. Walker and Sons of Leicester samples of their "Wolsey" underwear in different thicknesses. We have given the garments, which answer to the tests for pure wool of good quality, a thorough trial and we recommend them to our readers. They have a soft finish which makes them very comfortable to wear and they are thoroughly well cut. They are guaranteed unshrinkable and the manufacturers inform us that the goods are made in their factories under the most hygienic conditions. A member of our staff who fences regularly says that the garment which we asked him to try for us—it was a jersey of medium thickness—is the most comfortable jersey in which to fence that he has yet worn, and anyone who knows how profusely the fencer sweats and how essential it is that his movements should be made with the utmost rapidity will recognise that the testimony is of value. We consider that in their "Wolsey" underwear Messrs. Walker and Sons are providing the public with excellent wares.

Calmette's and Pirquet's reactions were of equivalent value or not. He divided the individuals into three distinct groups—namely, cases of tuberculosis with positive clinical symptoms, cases of suspected tuberculosis, and non-tuberculous cases. In each group the observations were made at the same time. The first group consisted of 33 cases, of whom 17 were treated by Pirquet's method of cutaneous inoculation with tuberculin and 16 were treated by Calmette's method of instillation of a drop of a solution of tuberculin of 1 per cent. into the conjunctival sac. Pirquet's method gave [illegible] positive and two negative results while Calmette's method gave 12 positive and four negative results. The patients included cases of meningitis, peritonitis, lupus, cold abscess, caries of bone, pulmonary tuberculosis, and lymphoma of the neck. The last-named cases gave negative results by Pirquet's method whilst Calmette's method failed to produce any reaction in these as well as in the cases of lupus and caries of bone. The second group consisted of 33 cases, [illegible] of which were treated by Pirquet's method with [illegible] positive results, whilst 17 were treated by Calmette's method with 12 positive results. The patients comprised cases of bronchitis, pleuritis, [illegible], and catarrhal disease of the lungs. The third group consisted of 25 cases free from any suspicion of tuberculosis. Of this group 14 patients were treated by Pirquet's method with four positive results whilst 11 were treated by Calmette's method with two positive results. Dr. Kremer took care to select cases as much as possible similar to each other for the control tests. Wherever possible both tests were used in the same individual at the same time. Pirquet's reaction sometimes showed itself five hours after the inoculation but as a rule the effect was obtained in 24 hours and lasted from four to six days. Once it was visible for 11 days. Calmette's reaction occurred, as a rule, six hours after application but in one instance only after 24 hours; it lasted mostly from four to five days but in two instances for eight and 12 days respectively. In five cases the cutaneous reaction was positive whilst the ocular reaction failed to show the presence of tuberculous disease, and in four cases the eye was severely affected for some days. Dr. Kremer therefore concludes that of the two methods the cutaneous one is the more trustworthy, the easier, the less severe, and the less painful.

Regulations Concerning Phosphorus Poisoning.

The efforts of the sanitary and health departments with regard to the inspection of factories have resulted in the issuing by the Government of new regulations for the manufacture of matches and other articles in which the poisonous yellow phosphorus is used. The following points are worth mentioning. No person under 18 years of age and no woman who is either more than four months pregnant or has been confined within the preceding six weeks may be employed on the premises. The workers must be employed by turns in the different departments, being engaged in each for only four weeks, so that they do not come in contact with the phosphorus emanations oftener than every three months. Special attention is paid to ventilation and the regulations require it to be inspected daily. The premises where articles manufactured with phosphorus are stored must be provided with double doors and the persons engaged there must also change their occupation every few weeks. The factory workers must have special prophylactic and hygienic facilities. They must, for instance, have suits of working clothes with sleeves fitting closely at the wrists; [illegible] rooms and mouth-rinsing utensils must also be provided by the owner of the factory, their teeth must be regularly inspected, and a first-aid box containing antidotes must always be at hand.

Osteomalacia and Adrenalin.

An interesting discussion took place recently at a meeting of the Lemberg Medical Society when several cases of osteomalacia were exhibited. Dr. [illegible] showed a woman aged [illegible] years who had been confined to bed since her last labour [illegible] years ago because she had pain in her bones and could not walk. The measurements of the pelvis and other bones had not changed during treatment, which consisted of daily injections of adrenalin in increasing doses, beginning with half a cubic centimetre (eight minims) of a solution of strength 1 in 1000. The result of 25 injections was very satisfactory as the patient could walk about without experiencing any unpleasant sensations. In addition to this example of chronic osteomalacia another patient was shown suffering from the acute type; she also was unable to walk and could hardly move her lower limbs. Tenderness on pressure was present and a marked feature was that all the long bones and the ribs could be bent on pressure. When she first came under observation she was seven months pregnant. Following Bossi's suggestion she was at once treated with one daily injection of one cubic centimetre of a solution of adrenalin of strength 1 in 10,000. During the first four days headache, high blood pressure, and a red hue of the face were noticed, but after the first week these effects disappeared until an increased dose was given which always caused unpleasant symptoms. Altogether [illegible] injections were given, with the result that the pains disappeared, the bones became hard, and the pelvis did not change its shape. In the discussion it was maintained that different observers had obtained different results, perhaps on account of using adrenalin obtained from different manufacturers. The danger of the indiscriminate use of this substance was pointed out, as in some animals, especially rabbits, arterio-sclerosis could be produced by injections of adrenalin. The use of phosphorus and salts of lime was recommended for the treatment of osteomalacia. This disease was said to be very rare in some countries and to be most often met with in marshy districts.

Congress on Thalassotherapy.

The Fourth International Congress on Thalassotherapy will be held at Abbazia on the Austrian coast of the Adriatic sea. The therapeutic use of natural mineral waters will be included among the subjects and the discussions will deal not only with the treatment of disease by sea air, sea water, and sea voyages but with hydrotherapy and balneological questions. The congress will meet from Sept. [illegible] to 30th and will no doubt attract many medical men from the Riviera, from Italy, and from the Netherlands.

Surgery of the Lungs.

At a recent meeting of the [illegible] Medical Society Dr. [illegible] gave an interesting synopsis of the present condition of the surgery of the lungs. He said that the prevalent idea that pneumothorax must be avoided was the chief obstacle to the development of this branch of surgery. Sauerbruch's low-pressure apparatus, Brauer's high-pressure apparatus, and Kuhn's method of producing high pressure by peroral tubage had now made the way for the surgeon an easy one, but all these methods were too complicated for ordinary operators. The same object was attained by suturing the costal and pulmonary pleuræ together. The principal danger of pneumothorax was the sudden change of blood pressure in the lesser circulation and not the diminution of the respiratory surface of the lungs. The most favourable results were obtained in operations on gangrenous cavities or abscesses of the lung. For the cavities of bronchiectasis the prognosis was worse and those associated with tuberculosis were unsuitable for operation. Tumours had not often been treated surgically as the diagnosis was difficult and the prognosis was doubtful. The production of pneumothorax for the treatment of pulmonary tuberculosis had been advised by Murphy and practised sometimes with injection of nitrogen rather than of air, because the latter was absorbed too quickly. The method was useful only in unilateral cases. The latest development in this direction had been achieved by Trendelenburg who attacked a thrombus of the pulmonary artery artificially produced in a calf and succeeded in saving the animal's life.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready *means of* finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the *Office not later than* Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or *Subscriptions* should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other *Railway Bookstalls* throughout the United Kingdom. Advertisements are also received by them and all other *Advertising Agents.*

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

8, in which it was stated that she understood "that medical men in the county of Essex have refused attend any emergency summons from a midwife. Also the East-End of London the medical men have issued ir refusals, and from correspondence she had received fears that the same movement is unfortunately spreading Norfolk." A letter was considered from Dr. C. J. Nepean ngridge suggesting that midwives should possess some owledge of the warning symptoms of cancer of the uterus. the request of the Board the chairman undertook to draft eaflet on the subject for distribution to midwives, teachers, d local supervising authorities. A letter was considered m the Clerk of the London County Council as to the prosed inspection of the maternity wards of the Poplar workuse. The Board decided that the Local Government Board ould be requested to reply to the questions comprised in the structions to the Board's inspector so far as applicable.

Association of Medical Men Receiving sident Patients.—The annual general meeting of this sociation was held at 26, Bryanston-street, W., on arch 31st, Dr. David Walsh, the President, being in the chair. e honorary secretary reported a considerable increase in e number of applications from persons desiring to place ident patients with medical men, and also of medical men shing to join the association. One effect of transferring e secretaryship from Bournemouth to London had been at it was found possible to expedite the work of bringing plicants and medical men into contact with each other, d consequently the number of patients placed with embers of the association had shown a distinct increase. he balance in hand was substantial and there were no utstanding accounts. The honorary secretary was thanked r the time and trouble which he had given to the work of the ssociation and various alterations which experience showed be advisable were made in the rules. The amount ayable by members for joining the association was reduced rom £1 10s. 6d. to £1 1s., the subscription in subsequent ears being retained on the old basis—namely, 5s. The inciple that no member should take less than three guineas week for a patient, except under exceptional conditions, was reaffirmed. A discussion took place as to the means for making the association more widely known, as it was felt that owing to its voluntary nature and its government by members, all of whom are registered medical practitioners, the profession would gladly support the association even more warmly than in the past if they were better acquainted with it.

Practical Training in Food and Meat Inspection.—A special course of training for commissioned officers and professional men preparing for the examination for inspectors of meat and other foods, conducted by the Royal Sanitary Institute, will commence on Monday, April 27th, at 7 P.M., and will consist of practical training in the inspection of foods and meat, including demonstration on live cattle and sheep, slaughtering and dressing of animals, names and situations of the organs, diseases of animals, methods of stalling, arrangement of markets and byres, &c., at a cattle market. Demonstrations will also be arranged at a knackers' yard, where instruction regarding the flesh and organs of the horse will be given. The course will include ten lectures and demonstrations by Mr. James King, M.R.C.V.S., veterinary inspector of the Metropolitan Cattle Market, on Meat Inspection, of which the six lectures will be delivered in the Parkes Museum, at 5.30 P.M., on the following dates: Tuesday, April 28th; Wednesday, April 29th; Tuesday, May 5th; Tuesday, May 12th; Wednesday, May 13th; and Friday, May 15th. The four demonstrations will be given at the Metropolitan Cattle Market at 3 P.M. on Saturday, May 2nd; Saturday, May 9th; Saturday, May 16th; and Saturday, May 23rd. Two lectures will be delivered by Professor H. R. Kenwood in the Parkes Museum at 5 P.M. on Monday, May 11th, and Thursday, May 14th, on Tinned and Potted Food, and Milk, Butter, and Cheese respectively. Four lectures will be delivered by Colonel J. Lane Notter, R.A.M.C., in the Parkes Museum at 5 P.M. on the following dates:—Monday, May 18th, Fish, Eggs, Tea, Coffee, Cocoa and Chocolate, and Lime Juice; Tuesday, May 19th, Wheat, Rice, Arrowroot, and other Grains, Potatoes, Flour, Bread, Biscuits, and Sugars; Wednesday, May 20th, Succulent Vegetables and Fruits, Jams, the Condiments—Vinegar, Pepper, Mustard, and Prepared, Concentrated, and Preserved Foods; and Thursday, May 21st, Alcoholic Beverages—Beer, Wines, Whisky, and Brandy. On Friday, May 22nd, a visit to a factory for preparation of concentrated and preserved foods has been arranged. In addition to the special lectures the students will have the privilege of attending the lectures and demonstration (in connexion with the course for sanitary officers) given in the Parkes Museum, Margaret-street, W., during April and May by Major J. A. Meredith, F.R.C.V.S., Dr. E. Petronell Manby, medical inspector, Local Government Board, and Mr. King. Inspection and demonstration in fish inspection and in knackers' work will also be given in this course, for which the fee is £5 5s. Those desirous of attending the course are requested to send in their names at once to Mr. E. White Wallis, the secretary of the institute, Margaret-street, W., who will supply more detailed information.

British Balneological and Climatological Society.—The annual provincial meeting of this society will be held at Harrogate on Saturday, May 16th, at 3.15 P.M., when the Fellows will meet at the Royal Baths, where they will be received by the Mayor and Bath officials. A reserved corridor carriage will leave King's Cross Station, London, at 10 A.M., arriving at 2.15 P.M. Short papers will be read on the Meteorology and Geology of Harrogate by Mr. Fox Strangways, and on the Therapeutics of the Waters and Treatment by Dr. Frederick Lever, President of the Harrogate Medical Society. At 4 30 P.M. the society and its guests will inspect the Harrogate Baths. At 7 P.M. the Fellows' dinner will be held at the Hotel Majestic, Harrogate, and at 9 P.M. the Fellows and their guests are invited by the Kursaal Committee to attend the entertainment at the Kursaal without charge. On the following day (Sunday) with the coöperation of Mr. G. R. Green, medical officer of health of Ripon and a member of the society, a trip by train or motor-cars will be made to Ripon which will be reached in time for the service at 11 A.M. at the historic cathedral. At 1 P.M. lunch will be taken at the Spa Hotel, Ripon, by invitation of the proprietors of the hotel, free to Fellows only. At 2 30 P.M. a visit will be paid to Studley Royal, the seat of the Marquis of Ripon, and the monastic ruin of Fountains Abbey. The return to Harrogate will be made in time for dinner. On Monday, May 18th, a train will leave Harrogate at 10 10 A.M. for the return journey to London. Fellows may take their wives and daughters and are allowed to invite medical guests who will all be permitted to dine at the Fellows' dinner and their hotel expenses will be charged at the same rate as for the Fellows—viz., 1 guinea each from Saturday afternoon to Monday morning, including all meals excepting lunch on Sunday. The honorary secretaries are Dr. S. P. Sunderland, 11, Cavendish-place, Cavendish-square, London, W., and Dr. F. A. de T. Mouillot, Elm House, Harrogate, who desire to learn as soon as possible the number of Fellows and guests likely to be present.

International Drawing Congress.—The British committee of this congress, of which the patron is H.R.H. the Prince of Wales, and the chairman Sir J. E. Gorst, K.C., LL.D., is finding some difficulty in making its significance known in this country and arousing the local interest and activity which are necessary to prepare for it. Foreign Governments assist their own delegates and some 25 countries will be represented, but as far as this country is concerned the expenses of the congress must be defrayed by voluntary subscription and towards the £5000 required only about £1700 have been given or promised. The first congress was brought about in Paris during the exhibition of 1900 by the Friendly Association of Teachers of Drawing (L'Association Amicale des Professeurs de Dessin). The second congress was held at Berne in 1904 and was attended by 400 members of the association whose expenses were partly defrayed by the French Government. The British representatives at these congresses were deeply impressed by the enthusiasm of their foreign colleagues, by the very liberal measure in which continental schools are assisted by public funds, and by the clear and strong claims made and allowed for drawing, first as an educational exercise and then as a preparation for industrial and professional life. The committee states that it is not the usual practice in this country to correlate art with other studies and that business men in general have not been taught to think of art as a practical thing. Closer coöperation is desired in this country between the schools where applied of distilling or to the good canary wine employed in the mixing.

A tablet in memory of Francis Anthony, who lived in St. Bartholomew's-close, may be seen on the north wall of the Church of St. Bartholomew the Great. Gwinne had at least four famous colleagues at Gresham College—namely, Henry Briggs, the great mathematician, who improved Napier's table of logarithms; John Bull, the organist and composer and the latter's successor as Gresham professor of music; Thomas Clayton, who became professor of physic and anatomy at Oxford. He had the reputation of being a great linguist "to whom the great Avicenna might speak and be understood without an interpreter." Also George Mountayne (Montaigne or Mountain), Professor of Divinity, who eventually became Archbishop of York. The story is that he strained every nerve to get this last preferment and that when Charles I. was discussing the question of the vacant see in his presence he wittily remarked to the King: "Hadst thou faith as a grain of mustard seed thou wouldst say unto this Mountain, 'Be removed into that see!'"

Peter Mounsell (1607–1615) studied medicine in Oxford, Cambridge, Paris, and Padua, and afterwards made a second tour on the continent to visit the Universities of Basle, Strasburg, and Leyden, where he apparently took the degree of doctor of physic. He was Gresham Professor for eight years and practised in the city, being buried, like our founder, in St. Helen's Church.

Thomas Winston (1615–1643 and 1652–1655) was the son of a carpenter and was born in the year 1575. He was educated at Clare Hall in Cambridge, where he had a Fellowship and took the degree of Master of Arts, after which he became Doctor of Physics at Padua. While abroad he attended the lectures of celebrated anatomists, Fabricius and Prosper Alpinus at Padua and Caspar Bauhine at Basle. He eventually settled in London, where he became eminent in his profession. He received a doctor's degree at Cambridge and became Fellow of the College of Physicians in London. Among his unsuccessful competitors for the post of professor of physic at Gresham College in 1615 was the younger son of Mr. John Fox (the celebrated martyrologist), Dr. Simeon Fox, who was the last President of the College of Physicians who used to ride on horseback in London to visit his patients. Dr. Winston held his professorship in this College till the year 1642, by which time he had acquired a handsome fortune, when he suddenly and somewhat mysteriously left England, possibly compelled to do so for political reasons. When he had been absent from this country for six months Dr. De Laune was chosen in his place. Dr. Winston remained in France some ten years and returned to this country in 1652, when he made his peace with the Government and was restored to the possession of what he had lost upon going abroad. But by this time he was advanced in years and did not long enjoy his professorship, for he died in 1655, being then 80 years of age. Meric Casaubon called him "the great ornament of his profession" and Dr. Hamey commended him for keeping up the dignity of the faculty against the apothecaries. He never seems to have published anything during his life but after his death a treatise came out with this title: "Anatomy lectures at Gresham College by that eminent and learned physician, Dr. Thomas Winston, London, 1659." A second edition was called "The Compleat Anatomist" and is said to have been in some ways better than any other work on anatomy then extant in English. Its chief interest at the present time to us is that the book contained no mention of Harvey's great discovery of the circulation of the blood which had been announced at the College of Physicians in 1616 and given to the world at large since 1628. Winston was well read in Galen and in Latin authors, but held the old belief that there were openings between the two ventricles of the heart, and that the arteries transmitted as well as blood vital spirit formed in the left ventricle. During Winston's first term as professor Sir Kenelm Digby, Admiral, philosopher, and chemist, spent two hermit-like years at Gresham College, with beard unshorn, in sorrow for his beloved wife, whom he was supposed to have poisoned by accident by giving her viper's flesh in broth to heighten her beauty.

During Winston's long term of office he had many eminent contemporaries at Gresham College, of whom at least four must be singled out for special mention. 1. Edward Gunter, his colleague in the astronomical chair, invented the sector, and was the first to calculate tables of logarithms for sines and tangents, besides making many other inventions and improvements in mathematics. He was the first to coin the words cosine, cotangent, and cosecant, and his name has been perpetuated in "Gunter's scale" and "Gunter's chain," still constantly used in land surveying. 2. Henry Gellibrand, his successor, contributed much to the improvement of navigation by following up Gunter's work on the variation of the magnetic needle. He seems to have been a plodding, industrious mathematician, without any special genius. 3. Daniel Whistler, professor of geometry, was M.D. of Leyden and Oxford Universities, one of the original Fellows of the Royal Society, and died as President of the College of Physicians. His thesis on taking his degree at Leyden was "On the English Disease of Childhood, called Rickets," and this is the earliest printed account of that disease. Dr. Norman Moore tells us that the author was dissatisfied with the vulgar name "rickets" and proposed to substitute for it "pædossplanchnosteocaces," which fortunately no one has been barbarous enough to adopt. Whistler practised his profession in London, but died very much in debt, and was accused of having taken insufficient care of the property of the College of physicians. Samuel Pepys described him as "good company and a very ingenious man," and Evelyn called him "the most facetious man in nature." 4. More remarkable than any of these was Sir William Petty, professor of music. Though the son of a clothier he proved to be an universal genius, statesman, and one of the earliest political economists. He took the degree of M D. Oxford, where he became professor of anatomy, then physician to the army in Ireland, Fellow of the College of Physicians of London, one of the founders of the Royal Society, and eventually Surveyor General of Ireland. While acting as deputy to the professor of anatomy at Oxford in 1650 he obtained a wide reputation by reviving the supposed corpse of one Ann Greene who had been hanged for the murder of her illegitimate child and pronounced dead by the sheriff. The medical evidence at the trial corroborated the woman's statement that the child was still-born, in spite of which she was condemned to death. After hanging for the usual time she was cut down and handed over to the doctors for dissection. It was then discovered that she was still breathing, and, by the aid of restoratives, regained her health and was granted a free pardon. The event was regarded as a special Divine interference on behalf of an innocent and betrayed woman, and several pamphlets and poems were written in Oxford upon the occasion, one set of Latin verses being by Christopher Wren, who was then an undergraduate.

Among many other inventions Petty invented a double-bottomed ship to sail against wind and tide, which was considered one of the most wonderful discoveries of the day. On one occasion, being challenged to fight a duel and having the right to name the place and weapon, he proposed a dark cellar and an axe, in order, being short-sighted, to put himself upon an equality with his adversary. The challenge was thus turned into ridicule and the duel never took place. When in London his house was in Piccadilly, where Lincoln and Bennett now sell hats. Petty was twice offered and refused a peerage and one likes to think that possibly some of the statesman-like qualities of this great man have been handed down to his descendant, the present Marquis of Lansdowne.

Paul de Laune (1643–1652) was appointed to Dr. Winston's professorship during his absence. He was the brother of Gideon de Laune, a wealthy apothecary in London, who was one of the first assistants appointed by the Charter of the Apothecaries when they became separated from the grocers in the year 1617. He was also related by marriage to Dr. Argent, who was eight times President of the College of Physicians. De Laune studied at Cambridge and afterwards at Padua, where he was created Doctor of Physic. Later, he took the same degree at Cambridge and became a Fellow and senior Censor of the College of Physicians. He practised in Dublin, where he was physician to the Viceroy of Ireland, until he succeeded Dr. Winston at Gresham College. The restoration of the latter was a great blow to him, as it removed from him his chief means of support. Though then about 70 years of age he accepted an offer from Oliver Cromwell and was appointed physician-general to the fleet upon an expedition to Hispaniola under Admiral Penn. The expedition was repulsed by the Spaniards and the troops then sailed to Jamaica where they had better success, for they took the town, drove the inhabitants into the woods, and made a settlement, which has been one of our flourishing colonies ever since. Dr. de Laune apparently died in or near

Appointments.

ccessful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BTON, W. E., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Post Office at Streatham.

ALBY, A. W., L.R.C.P. & S. Edin., has been appointed Assistant Medical Inspector of Schools for the Frome District of Somerset.

IX, CHARLES, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Officer of Schools for the Shepton Mallet District of Somerset.

OMINY, GEORGE HERBERT, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Blandford (Dorset) Union.

OLLÄNDER, BERNARD, M.D., M.R.C.S., L.R.C.P. Lond., has been appointed Physician to the British Hospital for Mental Disorders and Brain Diseases, Camden-road, N.W.

AMES, A. M. A., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Kingscliffe District of the County of Northampton.

AWSON, J. WARD, M.R.C.S., L.R.C.P. Lond., has been appointed Physician to the British Hospital for Mental Disorders and Brain Diseases, Camden-road, N.W.

ANSON, KENRED, M.B., B.S. Dunelm, has been appointed House Physician to the Royal South Hants and Southampton Hospital.

OORHEAD, R. E., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Inspector of Schools for the Bath District of Somerset.

ICHOLLS, A. R., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Inspector of Schools for the Langport District of Somerset.

ORMAN, JOSEPH CLEMENT ARTHUR, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the *Poole (Dorset)* Board of Guardians.

ARSONS, J. F., M.R.C.S., L.S.A., has been appointed Assistant Medical Inspector of Schools for the Frome District of Somerset.

IERSE, THOMAS, L.R.C.S. Irel., L.K.Q.C.P. Irel., L.A.H., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wexford District of the County of Wexford.

POLLARD, G. S., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Inspector of Schools for the Frome District of Somerset.

SHIPWAY, F. E., M.D., B.C. Cantab., has been appointed Honorary Anæsthetist to Guy's Hospital.

THOMAS, FRANK LESLIE, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer and Medical Officer to the Workhouse by the *Barnstaple (Devon)* Board of Guardians.

WALTER, R. H., M.B., M.S. Edin., has been appointed Assistant Medical Inspector of Schools for the Yeovil District of *Somerset.*

WOOD, C. R., M.D., B.S. Durh., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Shoreham District of the County of Sussex.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bangor, Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £80 per annum, with board, washing, and lodging.

Bermondsey Medical Mission.—Senior Assistant (female). Salary £75 per annum, with board and lodging.

Blackburn and East Lancashire Infirmary.—Junior House Surgeon. Salary *£70 per annum*, with board, washing, &c.

Bootle Hospital for Infectious Diseases.—Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and apartments.

Bradford Children's Hospital.—House Surgeon. Salary £100.

Bridgend, Glamorgan County Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, attendance, and washing.

Bristol General Hospital.—Assistant House Physician. Salary £60, with board, residence, &c.

Bristol Royal Hospital for Sick Children and Women.—Out Physician.

Cancer Hospital (Free), Fulham-road, London, S.W.—Honorary Physician. Also Dental Surgeon.

Carmarthen, Joint Counties Lunatic Asylum.—Second Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance.

Clayton Hospital and Wakefield General Dispensary.—Junior House Surgeon, unmarried. Salary £80 per annum, with *board,* lodging, *and* washing.

East Suffolk and Ipswich Hospital.—Senior House Surgeon. Salary £80, with board, washing, &c.

Egyptian Government, Kasr El Ainy Hospital.—Resident Surgical Officer. Salary £250 per annum, with quarters, servants, washing, coal, and light.

Evelina Hospital for Sick Children, Southwark Bridge road, London, S.E.—Honorary Anæsthetist. Also House Physician for nine months, and House Surgeon for six months. Salary in each case at rate of £60 per annum, with board, residence, and washing.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, also Assistant Casualty Medical Officer, both for six months, and unmarried. Salary in each case £20, with board and residence. Also House Physician, unmarried, for six months. Salary £20, with board and residence.

Leicester Infirmary.—Second Resident Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

Lincoln County Hospital.—Junior House Surgeon, unmarried, for six months. Salary £30, with board, residence, and washing.

London Hospital, Whitechapel.—One Medical and Two Surgical Registrars. Salary in each case £100 per annum.

London Throat Hospital, 204, Great Portland-street, W.—Assistant Surgeon.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

Manchester, University of.—Senior Demonstrator in Physiology. Salary £150, rising to £200 per annum.

Margate, Royal Sea-Bathing Hospital.—Resident Surgeon. Salary at rate of £80 per annum, with board and residence.

Medical Mission Hospital, Settlement of Women Workers, Canning Town.—Assistant Doctor (female) for six months. Board, residence, and laundry.

Middlesex Hospital, W.—Second Assistant to the Director of the Cancer Research Laboratories. Salary £200 per annum.

Monmouthshire Education Committee.—Two Assistant Medical Officers (one male and one female). Salaries for each £250 per annum, rising to £300 per annum, and travelling expenses.

Northamptonshire County Council Education Committee.—School Medical Officer. Salary £300 per annum and travelling expenses.

Northumberland, Tynemouth Infirmary.—Two House Surgeons. Salary £80 per annum each, with rooms, board, &c.

Nottingham City Asylum.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, &c.

Paddington Green Children's Hospital, London, W.—House Physician, also House Surgeon, both for six months. Salaries at rate of 60 guineas per annum, with board and residence.

Poplar Hospital for Accidents, Poplar, E.—Assistant House Surgeon. Salary at rate of £80 per annum, with board and residence.

Preston, County Borough of.—Schools Medical Officer. Salary £250 per annum.

Preston, Lancashire Education Committee.—School Medical Superintendent. Salary £500 per annum, rising to £550, with expenses.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Assistant *Resident* Medical Officer for four months. Salary is at rate of £50 per annum, with board, residence, and washing. Also Physician to Out-patients.

Rotherham Hospital and Dispensary.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

Royal Dental Hospital, Leicester-square.—Morning House Anæsthetist. Salary £50 per annum.

Royal Navy, *Medical Department.*—Examination for not less than 15 Commissions.

Ryde, Royal Isle of Wight County Hospital.—Resident House Surgeon. Salary £100 per annum.

St. Andrews, University of.—Chandos *Professorship of Physiology* in the United College, St. Andrews.

St. George's Hospital.—Resident Anæsthetist. Salary at rate of £50 per annum, with board and lodging.

Singapore, Straits Settlements, Municipal Health Department.—Assistant Municipal Health Officer, unmarried. Salary $4200, rising to $4800.

Southampton, Free Eye Hospital.—House Surgeon. Salary £70, with board and residence.

Southend-on-Sea, Borough of.—Medical Officer of Health. Salary £550 per annum.

South Uist (Southern Division).—Medical Officer. Salary £77 10s.

Stafford, Staffordshire County Asylum.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with board, *lodging, and attendance.*

Stockport Infirmary.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

Sunderland Infirmary.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

Twickenham Urban District Council.—Medical Inspector of Schools. Salary £150 per annum. Also Health Visitor and School Nurse. Salary £85 per annum. Both females.

Ventnor, Royal National Hospital for *Consumption and Diseases* of the Chest.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Honorary Registrar and Pathologist.

Wolverhampton and Midland Counties Eye Infirmary.—House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

ARCHIBALD.—On April 7th, at Chapel-place, Ramsgate, the wife of Richard J. Archibald, M.R.C.S., L.R.C.P., of a daughter.

HAYWARD.—On April 9th, at The Grange, Wimbledon, the wife of *John Arthur Hayward, M.D.*, F.R.C.S., of a daughter.

MARRIAGE.

MACKAY—CROMMELIN BROWN.—By Spanish law, at Huelva, Spain (the domicile of the bridegroom), and afterwards on 13th April at the Langham Hotel, London, by the Rev. David Macdonald, B.D., of Manchester, William Alexander Mackay, F.R.C.S. and M.D. Edin., to Louisa Emily Crommelin, daughter of the late John Crommelin Brown, of the Indian Civil Service, and Mrs. Crommelin *Brown*, of 14, *Ainslie-place, Edinburgh.*

DEATH.

BROWNE.—On April 9th, Oswald Auchinleck Browne, M.A., M.D. Cantab., F.R.C.P., of Upper Wimpole-street, aged 52 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

He does not seem to have risen to any great eminence in either of his professions. He offended his father by his Jacobite opinions and by marrying against the Bishop's wishes.

John Woodward (1692–1728) on leaving school at 16 was apprenticed to a linen-draper in London, but escaping from that uncongenial employment he devoted himself entirely to study until he met with Dr. Barwick, physician to Charles II., who took him into his own house and for four years gave him instruction in anatomy, medicine, and other sciences. His patron obtained for him at the age of 26 the Gresham professorship of physic. In the following year he became a Fellow of the Royal Society and was often elected on its council, for his geological writings had already gained him a considerable reputation. He was created Doctor of Medicine by Tenison, Archbishop of Canterbury, in 1695, and afterwards received a similar degree at Cambridge. He became a Fellow of the College of Physicians, and also Censor and Goulstonian lecturer. As a practitioner Woodward seems to have relied chiefly on emetics and purges, and he is only remembered in medical circles in consequence of his controversy with the "princely" Dr. Mead and Dr. Freind on the utility of purging in the secondary fever of small-pox. Several abusive pamphlets were circulated on the subject and one day Mead and Woodward met accidentally under the gate of Gresham College and fought a duel. Several accounts of this duel have been published. One new to me has lately reached me through the kindness of Dr. J. F. Payne. It appeared in *The Weekly Journal or British Gazetteer* of Saturday, June 20th, 1719. As the account was written by Woodward it does not give Mead's version of the story. Woodward says that an accidental fall during the duel put him at Mead's mercy, when he was driving Mead before him. Afterwards Mead upbraided him with not having asked his life; Woodward replied that Mead had shown himself a coward and added: "that had he been to have given me any of his Physick, I would rather than take it have asked my life of him; but for his sword, it was very harmless; and I was ever far from being in any the least apprehension of it."

Woodward seems to have been somewhat quarrelsome, for in 1710 he was expelled from the Royal Society for conduct unbecoming a gentleman. Sir Hans Sloane, the celebrated physician and naturalist, was reading a paper before the society, when Woodward made some grossly insulting remarks. Sir Hans complained, and stated that this was not the only occasion on which Woodward's conduct had been offensive. Woodward was required by the Fellows to apologise but refused and was therefore expelled. Sir Isaac Newton was in the chair when the question of expulsion was discussed; and when it was pleaded in Woodward's favour that he was a good natural philosopher Sir Isaac remarked that "in order to belong to that society a man ought to be a good moral philosopher as well as a natural one." Woodward brought an action against the council to get reinstated but was unsuccessful. His merits as a geologist were of a very high order and the Woodwardian Professorship and Museum at Cambridge still exist as memorials alike of his learning and his munificence. He was also well versed in botany and was one of the founders of experimental plant physiology. He died at Gresham College and was buried near Sir Isaac Newton in Westminster Abbey, where his monument may be seen. During Woodward's residence in Gresham College he had as colleagues in the chair of rhetoric Charles Gresham, F.R.S., a kinsman of our founder, and John Ward, LL.D., F.R.S., F.S.A., the author of "The Lives of the Professors of Gresham College," published in 1740, a valuable biographical work upon which I have freely drawn in preparing this lecture.

Henry Pemberton (1728–1771), mathematician and physician, began his studies under the care of John Ward, Gresham professor of rhetoric, who was then a schoolmaster. On choosing the profession of medicine he went to Leyden to study under Boerhaave who was the most eminent physician of his time. From Leyden he proceeded to Paris to continue his mathematical and anatomical studies and thence to London, where he attended the wards of St. Thomas's Hospital in order to become acquainted with English practice. At the age of 25 years he took the M.D. degree at Leyden and on his return to London became the intimate of some of the most distinguished men of the day, including Sir Isaac Newton and Dr. Mead. He assisted the former in preparing the third edition of the "Principia" and in writing an account of his philosophical discoveries, while the latter had his literary assistance in his "Treatise on the Plague." He became Professor of Physic at Gresham College at the age of 34 years, but delicate health prevented his entering actively on the duties of medical practice. In 1746 the fifth London Pharmacopœia appeared as practically a new work, for the former editions were more mediæval than scientific. The first London Pharmacopœia was printed in 1618, just one century after the foundation of the College of Physicians, and was a small folio of 184 pages; its formulæ were distinguished for the multiplicity of inefficient substances massed together; no less than six contained more than 40 ingredients, and one consisted of more than 130 constituents.

Thanks to Pemberton, who was one of the best chemists of his age, and who devoted seven long years to chemical and pharmaceutical experiments necessary for the purpose, the fifth Pharmacopœia may be considered the first scientific one published in this country. On the eve of its appearance Dr. Mead reminded the College of Physicians of Dr. Pemberton's valuable services, and considered that these entitled him "to a suitable acknowledgment such as might be worth his acceptance, not as an operator, but consistently with his true character as a gentleman, scholar, philosopher, and physician." It was then resolved that Dr. Pemberton should have the copyright of the new Pharmacopœia, the sum of 100 guineas, and be reimbursed for all his expenses. Three years before his death the trustees sold Gresham College to His Majesty's Government for a paltry £500 a year, they contributing £1800 towards the expense of pulling down the college and building an Excise Office on the spot. As a necessary consequence of this unfortunate decision the professors were obliged to vacate the college and were granted £50 per annum in lieu of residence. But Dr. Pemberton seems to have refused these terms and would not leave until he was granted a further sum of £50 per annum, free of all taxes and deductions. He died at the age of 76 years, having been a voluminous writer all his life. His contributions to the Transactions of the Royal Society, of which he was a Fellow, extend from the thirty-second to the sixty-second volume.

Thomas Healde (1771–1789) was a Doctor of Medicine of Cambridge, a Fellow of the Royal Society, and physician at the London Hospital. He was a Fellow and Censor of the College of Physicians and seems to have delivered all possible lectures there—Gulstonian, Harveian, Croonian, and Lumleian. He died in 1789 in very reduced circumstances, leaving his widow and family in the greatest destitution. The College granted his widow a special bounty of £100 and helped to start her as midwife. He was the first of the Gresham professors of physic who was allowed to be married.

Christopher Stanger (1789–1834) began his medical education by an apprenticeship to a surgeon at Newcastle-upon-Tyne, after which he proceeded to Edinburgh, where he took the degree of Doctor of Medicine. He then spent four years in visiting the more celebrated medical schools on the continent, Paris, Montpellier, Vienna, Göttingen, and Leyden. On settling in London he became a Licentiate of the College of Physicians, Gresham Professor of Physic, and physician of the Foundling Hospital. He retained his professorship until his death at the age of 75 years. Munk says that he was a person of extensive attainments and great energy of character, and he obtained much notoriety in his day in consequence of his contest with the College of Physicians, for he maintained that it was the right of every well-educated London physician of fair character and mature age to be admitted a Fellow of that corporation, if found competent. The case was argued in the Law Courts for three days in 1797, but his petition was unanimously rejected.

The Gresham professors have occupied the chair of Physic, since its foundation, for an average period of more than 20 years each, while two of them, Pemberton and Stanger, each held their post for more than double that time.

Henry Herbert Southey (1834–1865) was the brother of Robert Southey, the poet-laureate. He began the study of medicine under a surgeon at Norwich, and at the age of 20 proceeded to Edinburgh where he acquired an unusual facility in the use of Latin, which he wrote and spoke fluently. This accomplishment was fully valued at Edinburgh and gave him a reputation which caused his society to be sought after by some of the best of his contemporaries. He retained his fondness for Latin all through his life and seldom failed to carry in his

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY.—3 P.M., Dr. F. Thomson: Demonstration on Fevers (at the North-Eastern Fever Hospital, St. Ann's-road, N.).

WEDNESDAY.—2.30 P.M., Diseases of the Skin (Dr. Meachen); Diseases of the Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Medical Out-patient Clinic (Dr. Whiting); X Rays (Dr. Pirie).

FRIDAY.—2.30 P.M., Operations. Medical Out-patient Clinic (Dr. Auld); Diseases of the Eye (Mr. Brooks); 3 P.M., Medical In-patient Clinic (Dr. Leslie).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (22nd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.).

THURSDAY (23rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (25th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Sheffield Telegraph, Daily News, Liverpool Courier, Army and Navy Gazette, Broad Arrow, Birmingham Post, Westminster Gazette, Bristol Mercury, Dublin Times, Glasgow Herald, Wimbledon Gazette, Manchester Dispatch, Yorkshire Post, Standard, Daily Telegraph, Morning Post, Sheffield Independent, &c.*

radius. A sagittal section of the parts concerned in Colles's fracture shows that the articular surface of the radius is set obliquely on the shaft. This obliquity may in some cases be due to a curve of the lower end of the radius, so that the concavity of the curve is directed forwards. Although this curve and the obliquity of the carpal articular surface may be in favourable specimens seen in the uncut bone, yet they are much better demonstrated in the bone which has been cut in a sagittal direction. The line of fracture, which is frequently transverse from side to side in that variety of fracture which is associated with the name of Colles and which is directed obliquely from behind downwards and forwards, is explained by a reference to the anatomy of the lower end of the radius. The curve forwards of the radius must be considered as an important factor in the production of the fracture at the lower end. Another important factor is the shifting of the main pressure from the hand through the radius and interosseous membrane to the ulna and so to the humerus. The essential element in the direction of the line of fracture consists in the presence of the pressure lamellæ passing mainly up to the posterior surface of the radius from the posterior part of the carpal articular facet. The question now arises as to whether the fracture begins on the anterior surface or on the posterior surface.

A reference to the breaking of a rod of steel or wood will help us to appreciate this point. If a rod be subjected to a breaking strain from each end there is a tendency first for the bar to bend and then to break. It is clear that the parts of the bar on the concave side of the curve will be compressed and that the parts on the convex side of the curve will be elongated the fracture first takes place on the convex side of the curve and later on the concave side. This statement of the results of a break in a bar of steel or wood is well illustrated in that variety of fracture known as greenstick fractures where the smash only occurs on the convex side of the curve and is then deflected up and down the shaft of the bone. If now we consider this section of the parts concerned in Colles's fracture, and which has passed through the trapezoid and scaphoid bones we see that the main pressure is transmitted through the posterior part of the radius. When a breaking strain is applied the anterior or concave part of the radius, which really corresponds to the convex side of the bar, is put upon the stretch and smashes first, and then the line of fracture is diverted along the course of the pressure lamellæ—i.e., along the grain of the bone. Hence the obliquity of the line of fracture from, as one would now prefer to describe it, below, obliquely upwards and backwards. The transverse line of fracture may be explained by the fact that in coronal sections of the bone the lamellæ are not nearly so pronounced as in sagittal sections and therefore will not affect the line of fracture to any marked extent.

FRACTURES IN THE REGION OF THE ELBOW-JOINT.

I now propose to consider one or two points in connexion with the bones of the elbow-joint. I would first ask you to consider the carrying angle. By means of this carrying angle the forearm is inclined outwards from the humerus when the limb is extended at the elbow-joint. Many explanations of this carrying angle have been given and references made to paper models in order to demonstrate the reason of its disappearance when the elbow-joint is flexed. I think, however, the carrying angle is of even more interest than it is credited with. The trochlear surface of the humerus is really a section of a spiral, but if the edges of the spiral were of equal height, owing to the direction of the spiral, which is from behind downwards and inwards, any angle which the forearm made with the arm would be inwards and not outwards. The carrying angle is formed entirely by the prominence of the inner lip of the trochlea below. The direction of the spiral and the prominence of the inner lip of the trochlea will therefore form two opposed forces, one tending to direct the forearm inwards, the other tending to direct it outwards—the force exerted by the internal lip of the trochlea prevails. We may therefore conclude that, even if the opposed surfaces of the elbow joint were in contact during the whole range of movement, great pressure would be exerted upon the inner lip of the trochlea as the arm was passing from the flexed to the extended position. This is therefore probably the cause of the smash of the internal condyle with the adjacent portion of the trochlea. I have reason, moreover, to believe that from sections of the flexed elbow-joint the inner lip of the trochlea is not in close contact with the corresponding part of the greater sigmoid cavity of the ulna. There appears, indeed, to be a fold of synovial membrane lying between the adjacent surfaces, and the external lip of the trochlea appears to bear the pressure through the flexed joint. As the joint is moved, therefore, from the flexed to the extended position the main pressure appears to shift from the external to the internal condyle. This observation is further borne out by a reference to the internal structure of the humerus. (Figs. 12, 13, and 14.)

FIG. 12.

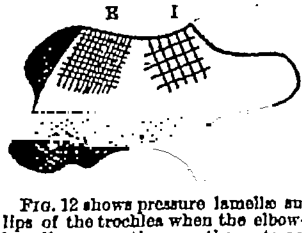

FIG. 13.

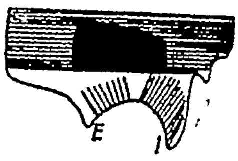

FIG. 12 shows pressure lamellæ supporting the internal and external lips of the trochlea when the elbow-joint is flexed. Note the stronger lamellæ supporting E., the external lip. Scale rather more a third life size.

FIG. 13 shows pressure lamellæ supporting the internal and external lips of the trochlea when the elbow joint is extended. Note the stronger lamellæ supporting I., the internal lip. Scale nearly life size.

FIG. 14.

In dealing with fractures in this region we may well ask ourselves why the coronoid process is not more frequently fractured. In the last edition of Sir John Erichsen's "Science and Art of Surgery" he deliberately forbears to speak of the symptoms. Skiagraphy has, however, revealed that what no less an authority than Hamilton considered as of very doubtful occurrence—namely, fracture of the coronoid process—does occur. Mr. E. W. H. Shenton tells me, however, that in most of his cases only the tip of the coronoid process is broken off.

Let us now consider the structure of the upper end of the ulna. In this diagram we see that the coronoid process is not so much a process relative to the shaft of the ulna as it is relative to the greater sigmoid cavity, and that it is supported by an enormously strong series of bars which pass into the anterior surface of the bone. The lamellæ which pass from the anterior surface radiate, as is usual, at right angles from the articular surface. Those from the upper part of the articular surface pass into the posterior surface of the shaft. The thick compact tissue on the posterior surface merges into the thin compact tissue of the olecranon process suddenly, no doubt predisposing to fractures of the olecranon. The lamellæ of the coronoid process which come from the lower part of the articular surface pass into a buttress of bone on the anterior surface of the shaft of the ulna. Fracture of the coronoid would, therefore, partake of the nature of a vertical smash of a long bone which is a variety of fracture not common. The enormous strength of the coronoid process is therefore much more apparent when we regard its internal structure. (Fig. 15.)

FRACTURES OF THE UPPER END OF THE HUMERUS AND OF THE CLAVICLE.

I must now pass to the consideration of certain anatomical points which have an important bearing upon the question of fracture occurring in the upper end of the humerus. First, let me briefly refer to some clinical details in connexion with fracture of the surgical neck of the humerus. This particular form of fracture may occur as a result of a fall upon either the abducted limb or upon the adducted limb. It may also occur—and in the cases collected for me very kindly by Mr. Martyn Lobb from the

The Gresham Lecture

ON

THE GRESHAM PROFESSORS OF PHYSIC.

Delivered at Gresham College on March 2nd, 1908,

By F. M. SANDWITH, M.D. Durh., F.R.C.P. Lond.,

GRESHAM PROFESSOR OF PHYSIC.

"Vita mortuorum in memoria vivorum est posita."—*Cic. Philipp. XI.*

GENTLEMEN,—On Jan. 16th, 1597, 17 years after the death of Sir Thomas Gresham, a threefold agreement was drawn up between the Mayor and Commonalty and Citizens of London of the first part, the Master Wardens of the Mercers' Company of the second part, and the seven Gresham professors already in residence in Gresham House of the third part, with regard to the good government of Gresham House according to the intent and meaning of the last will and testament of Sir Thomas Gresham. For the credit of the place, the increase of learning, and the greater honour of the Founder, it was unanimously thought meet and convenient that, in order to decide weighty matters in controversy and for the teaching of the principal and most material heads in all the several arts and sciences, certain solemn lectures should be delivered with great care and diligence at set days and times. And forasmuch as the public reading of the said lectures should be performed in that manner as would most tend to the glory of God and the common benefit of the people of this city, most of whom "understand not the Latin tongue, whereby the said lectures may become solitary in a short time, if they shall be read in the Latin tongue only," it was decreed that the lecture should be read in English for the benefit of the citizens, while it should be repeated in Latin for the sake of divers strangers of foreign countries "who resort to London and understand not the English tongue, yet will greatly desire to hear the reading of the said lectures, whereby the memory of the Founder in erecting the College for the increase of learning may be divulged, to the good example of foreign nations and the honour and credit of this honourable city." The bell which summoned merchants to the Royal Exchange was rung to give notice of the lectures, a practice which seems to have been discontinued after the Great Fire.

We are only concerned here with that clause of the ordinance which relates to the duties of the professor of physic:—

> And forasmuch as the greatest part of the auditory is like to be of such citizens and others as have small knowledge or none at all in the Latin tongue, and for that every man for his health's sake will desire to have some knowledge in the art of physick; it is thought good that the first lecture be read in the Latin, and the second in the English tongue. Touching the matter of the said solemn lecture, albeit the same is to be referred to the discretion of the reader; yet it is wished, that herein he follow Fernelius his method, by reading first physiologie, then pathologie, and lastly therapeutice; whereby the body of the said art may be better imprinted by good method in the studious auditors, rather than be disjointed and delivered out of order by exposition of some part of Galen or Hippocrates.

You will like to have a few particulars about the Fernelius who was held up as a model for the Gresham professors of physic to follow. Jean François Fernel (1497–1558) was a French physician who, as a youth, so distinguished himself at Paris in mathematics, philosophy, and languages that he was offered a professorship in one of those subjects. This offer he declined, preferring to become a physician, and he was eventually named professor of medicine in 1534. His extraordinary erudition, and the skill and success with which he sought to inculcate a more intelligent study of the old Greek physicians, gained for him a great reputation and ultimately the post of physician to the court of Henry II. and Catherine of Medici, the parents-in-law of Mary, Queen of Scots. The sixteenth century is memorable for the number of universities founded in Europe and for the general impulse towards freedom and independence due to the overwhelming conviction that thought must be freed from the fetters which had so long restrained it. Fernel earned the title of reformer because he taught that physicians should study the human body and think for themselves instead of blindly accepting all the writings of Galen and Hippocrates who had lived respectively 13 centuries and 19 centuries before him. Seeing the fruitlessness of mere speculation, he was one of the first to recommend that one ought to look for the cause of disease in the body itself and not in the fluids occasioned by the disease. The dissection of human bodies was not yet permitted, but we may assume that Fernel was of the same opinion as his Venetian contemporary, Realdo Colombo, who said that a man could learn more in one day by the dissection of a dog than by continually feeling the pulse and studying Galen's writings for many months together.

Let me now give you a brief account of the illustrious men who have preceded me in this post. Matthew Gwinne (1596–1607),[1] the son of a grocer, was a scholar and Fellow of St. John's College, Oxford, and in his younger days was appointed "Regent Master to read upon Music," for this was before the days when public professors were appointed and supported by fixed salaries to teach the liberal arts. But when he had taken his degree in arts he embraced the profession of medicine and practised as a physician in Oxford for several years. He was allowed to discontinue the lecture on music because "suitable books were difficult to procure, and the practice of that science was unusual if not useless." In 1592 he was chosen to reply in a Latin debate at Oxford for the entertainment of Queen Elizabeth, and it is reported that his witty handling of the matter and his discreet behaviour seemed to please her Majesty much. In the following year he was created doctor of physic, and we next hear of him as professionally attending Sir Henry Unton, the Ambassador of this country at the French Court. In March, 1596, he was chosen as the first professor of physic at Gresham College, being one of the two who were nominated by the University of Oxford, and his introductory lectures in 1598 consisted of an oration in praise of the founder and his institution. In 1604 he was admitted a candidate of the College of Physicians of London, or, as we should now call it, a Member, and in the following year he was made physician to the Tower. During that year James I., with his Queen, Prince Henry, and their courts went to Oxford, where they were entertained for three days with academical exercises of all kinds. Dr. Gwinne was specially prominent on the occasion, and took part in the two debates, whether the morals of nurses are imbibed by infants with their milk and whether tobacco smoking is wholesome or not. As the king was a professed enemy of tobacco and had written against the use of it this debate gave His Majesty an opportunity of expressing his own sentiments on the subject. On the same evening a Latin comedy was acted at Magdalen College, of which Dr. Gwinne was the author. The King was pleased with the acting of the students, although it did not keep him awake. A few months later Dr. Gwinne was admitted a Fellow of the College of Physicians and resigned his Gresham professorship in 1607, probably in order to marry. From 1608 to 1627 he was registrar of the College of Physicians and continued to practise in London where he was much esteemed both in the city and at court. In 1620, seven years before his death, he was appointed, with seven other Royal Commissioners, to draw up regulations for garbling (or sorting) tobacco before it was exposed for sale. He wrote several papers and was a man of intelligence, lively fancy, and poetic genius. He had read much and was well versed in all sorts of literature, accurately skilled in modern languages, and was much valued for his knowledge and success in the practice of his profession. His only medical work was an able treatise in Latin to prove that Francis Anthony's celebrated but secret remedy, called "potable gold," contained no gold at all, and that even if it did the virtues of gold as a medicine were much exaggerated. This Anthony (1550–1623) was a successful empiric who when examined in medicine before the President and Censors of the College of Physicians and being found ignorant was forbidden to practise. He disregarded this injunction and was in consequence fined and sent to prison more than once. He claimed that his secret remedy would cure all diseases and offered to exhibit his process of dissolving gold, which his adversaries declared was impossible. Accordingly a trial was held at the College of Physicians in 1609 before the Master of the Mint and other experts but when Anthony was given an ounce of gold he failed to dissolve it. Dr. J. F. Payne suggests that any efficacy which the cordial may have possessed was due to certain ethers formed in the process arm adducted and fixed to his side the inferior lip of the glenoid fossa comes into forcible contact with the surgical neck of the humerus. There are here four specimens of fracture of the surgical neck of the humerus showing that the line of fracture is transverse and that it lies opposite the point of contact between the inferior lip of the glenoid fossa and the surgical neck of the humerus.

---

[1] The dates within brackets after the professors' names show the years during which each occupied the chair of physic.

Now fracture of the surgical neck of the humerus may be associated with dislocation of the humerus from the glenoid fossa and a correct appreciation of the strength and position of the inferior lip of the glenoid process, which may be termed the glenoid buttress, helps to explain this not infrequent occurrence. But whilst it helps to explain the occurrence of a dislocated shoulder with a fracture of the surgical neck of the humerus it explains very well the occurrence of a fracture of the surgical neck of the humerus in conjunction with the reduction of a dislocated shoulder. In, for example, Kocher's method of reduction of a dislocated shoulder directions are given that the shoulder shall be adducted. At this time also the humerus is being flexed and internally rotated and the inferior lip of the glenoid fossa is therefore not only coming into forcible contact with the surgical neck of the humerus but is also exerting a cutting action. It will be well, therefore, for those who scoff at the method of reducing a shoulder-joint by exerting pressure upon the humerus with the stockinged foot to remember the existence of this glenoid buttress. One well-known provincial surgeon, now dead, held that it was not necessary for a surgeon to know anatomy. I venture to think that knowledge of this glenoid buttress and its relation to fractures of the surgical neck might save much trouble both to the patient and to the operator.

Of course, we must take into account at least two points in connexion with this anatomical fact—namely, that the inferior lip of the glenoid fossa comes into contact with the surgical neck of the humerus. The first may be put in the form of a question. Is not the scapula a moving bone and therefore is it likely that the humerus will impinge with sufficient force to smash the limb? The answer to this question is that when the arm is stretched out behind one with the limb adducted to the side the scapula is fixed and that not only is the force of the actual adducting force to be taken into account but also the pressure of the fall either on the hand or on the shoulder. Moreover, even if the scapula be moving, as it might conceivably be in reduction of a dislocation under an anæsthetic, if it be not moving so quickly as the humerus there will be the possibility of the humerus, so to speak, catching up the scapula, and the surgical neck coming into forcible contact with the inferior lip of the glenoid fossa. Two trains, one going at 60 miles and the other at 30 miles an hour, even if they be going in the same direction, will cause serious results if they happen to come into contact. Secondly, fracture of the surgical neck is frequently said to be due to muscular violence. The relation of the inferior lip of the glenoid fossa to the surgical neck of the humerus will afford an additional explanation of why this is possible. For the humerus will be broken over the inferior lip of the glenoid process as a stick is broken over the knee.

I have drawn your attention to the well-marked coracoid and axillary bars of the scapula which support the glenoid fossa and into which definite long lamellæ may be traced. By what are these bars supported? The axillary bar is supported by all the muscles attached to the scapula which pass to it from the trunk, notably the serratus magnus, trapezius, and latissimus dorsi.

FRACTURE OF THE CLAVICLE.

The coracoid bar is, however, rather differently supported, and we must pay some attention to this, as I hope to show that these supports are of great importance, especially in connexion with fracture of the clavicle. Now Mr. Lane has shown that in labourers who are in the habit of carrying considerable loads upon their shoulder the back part of the upper surface of the coracoid process is actually in contact with the clavicle. There may be a facet in the macerated bone indicating this condition. I would, however, venture to go further than this and say that in some cases in which particular occupation has played no part the coracoid process may be situated either in direct contact with the clavicle or so close to it that the tip of the index finger can hardly be introduced between the two bones. We may therefore conclude that the clavicle, fixed as it is at or near its sternal end by the interarticular fibro-cartilage and the rhomboid ligament, offers some support to the coracoid process when the coracoid bar is thrust upwards. Now if a swing inwards of the axillary bar takes place as well as an upward thrust of the scapula, and with it the coracoid bar be added to this inward swing, it will be clear from this model that the coracoid process is jammed against the clavicle between, or in the region of, the conoid and trapezoid ligaments. Now Mr. Henry Morris, Professor D. Hepburn, and other authorities have rightly laid stress upon the exact position of the surfaces of the trapezoid ligament. The surfaces are not anterior and posterior but are obliquely set, so that the so-called anterior surface looks upwards, inwards, and forwards, and the posterior surface looks downwards, outwards, and backwards. In one specimen which I show the surfaces hardly face forwards or backwards at all. If this position of the trapezoid ligament be accepted as correct it can hardly be considered to have much influence in suspending the scapula from the clavicle.

Now in the lower end of the radius and the upper end of the ulna and the two extremities of the humerus, as well as in the glenoid fossa of the scapula, it may be demonstrated that there are well-marked pressure lamellæ. We may therefore argue that if these bones indicate by their internal structure certain pressure lamellæ the pressure that is transmitted through them can hardly stop before reaching the clavicle but is transmitted into the clavicle in certain circumstances.

Of course, pressure may be transmitted through the acromion process and acromio-clavicular joint to the clavicle. Now how is this pressure transmitted through the coracoid process to the clavicle? Forcible contact without corresponding pressure lamellæ being developed would hardly be considered a good way of transmitting pressure to the clavicle, especially as the clavicle is such a slender bone and fixed by such strong ligaments at its inner end. Now I said that pressure might be transmitted through the acromion process to the clavicle, but there are two points in connexion with this statement that I would draw your attention to. First, the obliquity of the acromio-clavicular joint. There is rarely the same degree of obliquity in the articular surfaces of the acromion and clavicle. This is allowed for by the presence of a triangular fibro-cartilage and by the oblique position of the acromion process itself. The upper surface of the acromion process also looks backwards and outwards and the clavicular articular surface on its inner border looks upwards and inwards. Therefore if pressure be transmitted through the scapula and the clavicle the acromio-clavicular joint is not best adapted for such pressure. The second point is that if pressure be transmitted through the glenoid fossa and clavicle there is hardly any pressure exerted through the acromio-clavicular joint at all, the cartilage which lies between the clavicle and acromion process is not compressed even when great pressure is made, and if less than great pressure be used the synovial cavity on each side of the interarticular fibro-cartilage is not diminished in size or altered in shape.

From these considerations we may assert confidently that whilst one function of the conoid and trapezoid ligaments is undoubtedly to prevent underrunning of the clavicle by the acromion, and whilst this may be the only function of the conoid ligament apart from slinging the scapula upon the clavicle the main function of the trapezoid ligament is to transmit pressure passing from the scapula to the clavicle—e.g., when the arm is in the usual thrusting position. It is by the trapezoid ligament which is put upon the stretch that the main pressure which passes from the upper part of the arm to the clavicle does not pass through the acromio-clavicular joint. It is the stretching, or rather increased tension, of the trapezoid ligament when much pressure is transmitted which prevents undue pressure being made upon the acromio-clavicular joint. This, then, is the function of the trapezoid ligament—this its use and object to counteract it may be any tendency to dislocation in the acromio-clavicular joint, but to counteract it by taking the pressure off it.

This function of the trapezoid ligament and the part which it and the coracoid process play in transmitting pressure from the humerus and scapula to the clavicle is further illustrated by the internal structure of the clavicle (Fig. 17), which in two specimens I have here displays an arrangement of bony lamellæ in exact accordance with the function of the coracoid process and the trapezoid ligament. The compact tissue is thin over the surface of the outer inch of the bone and is joined by arching lamellæ interlacing with each other amaica, for he was never heard of after that time. As he ad children Ward presumes that he must have been a idower when he officiated at Gresham College. You will otice that most of the Gresham professors to whom I have eferred went to Italy to complete their medical studies, and specially to Padua, which was then at the height of its enown as a school of anatomy and medicine.

Jonathan Goddard (1655–1674) was the son of a rich hipbuilder and was educated at Oxford and elsewhere. He then became a practitioner in London, a doctor of physic of Cambridge, and a Fellow and Censor of the College of Physicians. He was a promoter and one of the original council of the Royal Society, to which he made 14 communications. After being chief physician to Cromwell's army in Ireland and Scotland he rode into London in triumph with that general in 1651 after the battle of Worcester. He then became Warden of Merton College, Oxford, one of Cromwell's Little Parliament, and and was appointed a member of the Council of State. Upon Dr. Winston's death he was elected Gresham professor of physic and when the fire of 1666 occurred in London he removed for a time from Gresham College with the other professors to make room for the Mayor and Corporation who for some years transacted their business there until the City was rebuilt. He died at the College in 1674 and was buried in St. Helen's Church. He was the first Englishman to make telescopes, and being a clever chemist he worked hard in his laboratory at Gresham College at that science. One of his papers read before the Royal Society was entitled "A Discourse upon Eggs, containing Ten Signs whereby to Distinguish New Eggs from those which are Stale." He not only prescribed but concocted medicines and published a treatise recommending that physicians should prepare their own remedies, on the grounds that apothecaries were ignorant and that they dared to prescribe for the sick as well as to compound medicines. His reputation was kept alive for years by certain volatile drops, which were his invention and bore his name; though long in great repute this nostrum is now entirely forgotten. The drops were used in faintings, apoplexies, lethargies, or other sudden and alarming attacks, and were praised by the great Dr. Sydenham who found them better than any other volatile spirits "for energetically and efficaciously attaining the end for which they are applied" On the continent they used to be prescribed under the name of the "*English drops.*" It is believed that they consisted of spirit of ammonia, to which other ingredients were added, such as dried viper and the skull of a person who had been hanged. Goddard is said by some to have sold the secret of his drops to Charles II. for £5000 and it is to be noted that traffic in secret remedies was not held to be improper at that time.

Three of his distinguished contemporaries can hardly be passed over in silence, Wren, Barrow, and Hooke. Sir Christopher Wren, versatile genius and most famous of English architects, became Gresham professor of astronomy in his twenty-fifth year. His rooms in the College soon attracted those men of science who founded the Royal Society, of which he eventually became President. Within a week after the great fire of London had been extinguished Wren was ready with a plan for rebuilding the City, which was not accepted, chiefly because it was too thorough and too far-seeing. He thus had time to reconstruct St. Paul's Cathedral. 52 churches, no two of which were alike, 36 of the companies' halls, the Customs House, and several private houses, so that all that part of London seen from Blackfriars Bridge seemed to have sprung from his energy. Of the churches I may single out one, a gem of architecture. St. Stephen's, Walbrook, which was greatly admired by Wren's contemporaries on the continent I need hardly remind you of his grand epitaph in St. Paul's Cathedral, which states that he lived more than 90 years, not for himself, but for the public good. "Reader, if you are searching for his monument, look around you!"

Isaac Barrow, the professor of geometry, celebrated divine and scholar, showed but little promise in early life of his great talents, for he had to be removed from Charterhouse School because of his propensities for fighting and for stimulating other boys to fight, while at home he was so troublesome that his father was once heard to say, that if it pleased the Almighty to take any one of his children he could best spare Isaac! We hear little of his fighting in after life, though at the age of 26 years, while sailing from Leghorn to Smyrna on his way to Constantinople to read the works of St. Chrysostom, he had the opportunity of showing marked courage during an attack on the vessel by an Algerian pirate ship. He was at one time tutor to the famous Isaac Newton. His learning was prodigious and when he became chaplain to Charles II. the king called him "an unfair preacher, because he exhausted every topic and left no room for anything new to be said by any one who came after him." I do not know whether his sermons would be appreciated in the present day, for they usually took more than one and a half hours to deliver. He died at the comparatively early age of 47 years and was buried in Westminster Abbey, where the inscription on his monument was composed by his great friend, Dr. John Mapletoft.

Robert Hooke, the inventor and author, was also a Gresham professor of geometry. Unlike Barrow, he showed extraordinary cleverness as a school boy and astonished his teachers at Westminster School by mastering the six books of Euclid in one week. He also prepared a model for rebuilding the city after the great fire and, though it was not accepted, he obtained the appointment of city surveyor. In 1674 the Royal Society returned to Gresham College to hold its scientific meetings there and in the same year the Gresham committee "in order to encourage Mr. Hooke in his curious and useful enquiries" allowed him, at the cost of £40, to erect an astronomical turret over his quarters in the College. He was curator of the treasures of the Royal Society and received the compliment of being created Doctor of Physic at Doctors' Commons by a warrant from Tillotson, Archbishop of Canterbury. Engaged to the last in philosophic research, he died in Gresham College and was buried in St. Helen's Church. He was the greatest mechanic of his age, but his brilliant erratic genius seldom allowed him to finish one investigation before hurrying on to the next. He divined the doctrine of universal gravitation before Newton but had not the mathematical ability to prove it.

It was in Goddard's time that Samuel Pepys was admitted a member of Gresham College and paid £2 for that privilege. It should not be forgotten that Gresham College was the cradle of the Royal Society.

John Mapletoft (1675–1679), physician and divine, after travelling on the continent and studying medicine in Italy became Doctor of Medicine at Cambridge and afterwards at Oxford, and practised in London, where he was made a Fellow of the Royal Society. He was on intimate terms with many eminent men, including Dr. Thomas Sydenham and John Locke. The former dedicated to him the first edition of his "Medical Observations," and at the author's request Mapletoft translated some of Sydenham's works into Latin. He and Sydenham are said to have been for seven years closely associated in medical practice. Mapletoft began his lectures at Gresham College by describing Harvey's work and his discovery of the circulation of the blood, but he resigned the professorship in 1679 in order to marry, after which he relinquished the study of medicine for divinity, being then more than 50 years of age. Locke's friendship for him is shown by what he wrote to him on his entering into Holy Orders: "I like our calling the worse since you have quitted it." Locke himself had at that time renounced the practice of medicine and was devoting himself to his 17 years' study as to what questions the human understanding was or was not fitted to deal with. Mapletoft took his doctor's degree in divinity and eventually became vicar of St. Lawrence Jewry, where he continued to preach until he was over 80 years of age. Ward says of him: "He showed a great neglect, if not contempt of riches, and esteemed it sufficient, if he had enough to pass easily through the world, and something to spare for good and pious uses.

Henry Paman (1679–1689) became a doctor both of medicine and laws at Cambridge, where he was Public Orator and Master of the Faculties. He also took the degree of Doctor of Medicine at Oxford, became a Fellow of the Royal Society, a Fellow of the Royal College of Physicians, and delivered the Harveian Oration in 1688. He enjoyed the friendship of Sydenham, who addressed one of his published writings to him. His only printed medical treatise seems to have been an epistle written to Sydenham just before he became himself Gresham professor. He resigned his professorship six years before his death.

Edward Stillingfleet (1689–1692), the son of a learned but militant Bishop of Worcester, became a Doctor of Medicine at Cambridge and was elected a Fellow of the Royal Society. After holding his post at Gresham College for less than three years he resigned it in order to marry, and he, too, went into Holy Orders after marriage and died as a Norfolk rector.

The conclusions I would put before you as worthy of consideration in respect of the anatomy of the parts relative to fracture of the clavicle are: 1. That no pressure, or very little, is transmitted through the acromio-clavicular joint, even when blows are struck upon the outer edge of the acromion process. This absence of direct pressure through the acromio-clavicular joint is explained by the presence of the trapezoid ligament and its attachment to the coracoid process of the scapula and the clavicle. 2. That the pressure which passes through the coracoid process and the trapezoid materially affects the internal structure of the clavicle. 3. The obliquity of the adjacent surfaces of the acromio-clavicular joint and the presence of the triangular fibro-cartilage still further diminish shock. 4. That by direct impinging of the coracoid process against the clavicle fractures of the clavicle between the conoid and trapezoid ligaments are produced, and that with such fractures not only is displacement possible but that impaction may also take place. 5. That by bending of the clavicle over the coracoid process fracture of the shaft of that bone may be produced.

SEPARATED EPIPHYSES.

The question of separated epiphyses and the influence of pressure lamellæ upon the line of fracture is well illustrated by a reference to these diagrams (Figs. 18 and 19, 20, 21, and 22). Frequently when a separation of an epiphysis takes place the line of solution of continuity does not occupy the total area of the epiphysial line. Thus a portion of diaphysis may be broken off from the main part of the shaft and produce considerable difficulty in reduction of the deformity. If we refer to these diagrams (those representing the clinical features I have copied from the work of Professor Hoffa upon fractures and dislocations) we shall find that the fracture producing separation of the epiphysis in these diagrams of separated epiphysis of the lower end of the tibia, the upper end of the humerus, and the lower end of the femur, has passed along the epiphysial line for two-thirds of its breadth, and has then been deflected along the course of the pressure lamellæ of the bone—in other words, along the grain of the bone.

ON SO-CALLED RHEUMATIC IRITIS.

BY C. HIGGENS, F.R.C.S. ENG.,

SENIOR CONSULTING OPHTHALMIC SURGEON, GUY'S HOSPITAL, ETC.

IRITIS dependent on rheumatism no doubt frequently occurs, but my experience is that a very large number of cases so called are due to the poison of gonorrhœa and the worst cases with few exceptions have this origin. The history of these cases varies but little. The patient, nearly always a man, comes to the ophthalmic surgeon with iritis and it is probably not the first attack. His age is generally over 30, but he may be younger, and he will give a history of gonorrhœa, often of repeated attacks, but in most cases he will not have had one immediately before the iritis commenced. More likely the last attack will have been some years previously; he may or may not have had so-called gonorrhœal rheumatism; in the majority of cases he has not. The iritis is severe; all the usual symptoms are well marked. Its chief distinguishing features are: it is painful, often severely so, there are swelling of the iris, generally much photophobia, a strong tendency for adhesions to form, though there is no very great amount of exudation, with much ciliary and conjunctival congestion. There are also a decided inclination to contraction of the pupil which strongly resists the action of mydriatics of which there is often a marked intolerance; a tendency to increased tension; a general intractability, rendering treatment most difficult and its results most disappointing; and an unlimited capacity for recurrences continuing through any number of years. It seems to me that the liability continues through the whole of sexual life, an opinion which is borne out by that of the late George Critchett, who was in the habit of telling his patients they would "grow out of it," the truth of which I have been able to verify in one at least of his patients who came under my care; he did grow out of it but not till he was over 60 years of age. I cannot say that I have ever seen a case which I could with certainty say was gonorrhœal iritis in a female, though I have seen some suspiciously like it; and I am not sure that some of the obstinate cases of irido-cyclitis with keratitis punctata so frequently seen in young and middle-aged women may not depend on gonorrhœal infection, though I have no direct evidence to prove it, and some of them are undoubtedly syphilitic.

The question one asks oneself is, Supposing we are right in believing that there is such a thing as gonorrhœal iritis (which there seems to me to be no reason to doubt), how is it brought about? The probability is that in many men who have had gonorrhœa severely and frequently there is left for any number of years in some part of the urino-genital apparatus a very much attenuated virus which gives no trouble locally, but from time to time becomes more active, and though still setting up no local irritation is capable after absorption of causing inflammation in synovial membranes or in the iris; in fact, it looks almost as if the iris becomes on occasions an excretory organ and tries to eliminate the poison, receiving considerable damage to itself in the attempt. There must also be a personal element or an idiosyncrasy in those who suffer, because the proportion of persons who have iritis to those who have had gonorrhœa is very small indeed.

That an attenuated virus capable of infecting which causes no inconvenience to the person affected by it may exist seems to be proved by cases of purulent ophthalmia in female children who are found to have a vaginal discharge from which the eyes have been inoculated and of which no mention has been made. In some of these cases I have the authority of the late Dr. J. W. Washbourn and of Dr. J. W. H. Eyre for saying that gonococci exist in both the conjunctival and vaginal discharges. As further proof I may instance cases of wives (of men who have had gonorrhœa and who have no notion of anything being wrong) becoming infected, not with an ordinary gonorrhœa, but by salpingitis, followed in some cases by septic peritonitis. Here it would appear that the virus, though too weak to infect the vaginal mucous membrane, is powerful enough to infect that of the Fallopian tubes.

The results of gonorrhœal iritis include all those consequent on iritis in its worst forms; synechiæ more or less extensive, occluded and excluded pupil, complete adhesion of the posterior surface of the iris to the lens capsule, bombé iris with its attendant evils, capsular cataract, glaucoma, with changes in structure of the iris, and loss of vision varying from slight impairment to total blindness.

Cases.

CASE 1.—A man, aged 42 years, first consulted me 1884. He had had iritis in both eyes previously on mo than one occasion, his left eye being considerably damaged and years before he had suffered from gonorrhœa frequentl When I saw him he had severe iritis in the right eye, muc conjunctival and episcleral congestion, and a good deal pain. The attack lasted about a month; he then began to g better and was convalescent in the course of a few day One peculiarity about this case was that as soon as he bega to mend he got well almost suddenly. In 1888 I attende him for another severe attack in the same eye. From 18 up to 1900 he had many attacks, some severe, others on slight and lasting only a few days, but I managed to pu him through them all without any further damage to eith eye. In 1903 I saw him and fitted him with glasses; he ha had no iritis for three years; vision of the right eye was and there were a few posterior synechiæ; that of the le was $\frac{6}{24}$ with many posterior synechiæ and some opacity the lens capsule. I saw him again in 1907; the vision of th right eye was $\frac{6}{9}$, with −.50 cyl., and that of the left was he had had no more iritis. Apparently he had "grow out of it" at about 60 years of age.

CASE 2.—The patient, a man, aged 43 years, first cam under my care in September, 1893, with a history of seve gonorrhœa some years before. He had had many attacks iritis, mostly in the right eye. Iridectomy had been performe in the right eye; there were total posterior synechia an some iritic products on the lens capsule; vision = $\frac{6}{60}$. I the left eye there were a few posterior synechiæ; visio = $\frac{6}{18}$, c. −1 25 cyl. axis horizontal $\frac{6}{9}$. Glasses for readin and distance were ordered. During 1894 and 1895 th patient remained free from iritis. Towards the end of 189 he had a severe attack in the left eye, but by the middle January, 1897, he had completely recovered. A few fres synechiæ had formed but the sight was not damaged. I April, 1898, he had another bad attack which lasted month, followed by a relapse, which prolonged it for a week In January, 1899, he had another attack lasting six week pocket either Horace or Virgil, or the letters of the elder Pliny. He graduated Doctor of Medicine at Edinburgh, settled as a physician at Durham, and then moved to London, where he successively became physician to the Middlesex Hospital, physician in ordinary to George IV., physician extraordinary to Queen Adelaide, Gresham professor of physic, which office he held until his death at the ripe age of 82, and Commissioner in Lunacy. Oxford University conferred upon him the honorary degree of Doctor of Civil Law, he was a Fellow of the Royal Society, and at the College of Physicians he became Fellow, Censor, and Harveian Orator.

According to Sir Thomas Watson, Dr. Southey was not unworthy of the name that his elder brother, the poet, had made famous. He was a great favourite among his acquaintances and friends, and on at least three occasions valuable legacies were bequeathed to him by men who were bound to him by no ties of blood or of professional obligation. As a consequence of his official appointment his practice lay chiefly, though not exclusively, among the insane. He lived in Queen Anne-street. He became an Elect of the College of Physicians in 1848 and lived to see the abolition of that order in 1860. The Elects were eight seniors of the College, who for more than three centuries, by a special statute of Henry VIII., had annually elected the President. Since 1860 their functions have reverted to the whole body of Fellows, as was originally the case under the provisions of the Charter.

Henry Powell (1865–1867), after studying at Guy's Hospital, took his M.D. degree at Oxford in 1839 and in the following year became a Fellow of the Royal College of Physicians. He successively became physician to the Tunbridge Wells Dispensary and Infirmary, senior physician to Coventry Hospital, and consulting physician to Rugby School. He died on May 18th, 1867, aged 58. I have not been able to find that he made any contributions to medical literature.

Edmund Symes Thompson (1867–1906), son of Dr. Theophilus Thompson, F.R.S., was born in 1837 and became a scholar and gold medallist at the University of London, where he took his M.D. degree, a Fellow of the College of Physicians, assistant physician to King's College Hospital, consulting physician to the Brompton Hospital for Consumption, and a Fellow of many scientific societies. His first Gresham lecture was delivered on Nov. 6th, 1867, at 1 P.M., which was then the appointed hour. Following in the steps of his 14 predecessors, his Latin lecture was followed by one in English, until 1876, when the Latin discourse was discontinued on account of the small audience. I am told that those who attended the Latin lecture were chiefly masters and "Grecians" from Christ's Hospital and St. Paul's School, both then within the City limits, and that they were more interested in the style of the dead language than in the matter of the lecture. The attendance, however, at his lectures in English averaged more than 200, a sufficient proof of his popularity. His last lecture was given on April 27th, 1906, for he was taken ill in August and died on Nov. 24th of that year. His memory is yet very green in the minds of his friends and I may refer others who want to know more of his life's work to the obituary notices of only a year ago.

> "Were honour to be scann'd by long descent
> From ancestors illustrious, I could vaunt
> A lineage of the greatest, and recount
> Among my fathers, names of ancient story,

A MEDICAL OFFICER OF HEALTH FOR WORTHING.—Mr. R. H. Wilshaw, M.B., Ch B. Vict., D.P.H. was on April 16th appointed medical officer of health of Worthing and East Preston at a salary of £250 per annum and an additional £250 per annum for services in connexion with the Worthing isolation hospital and the medical inspection of school children in Worthing. Dr. Wilshaw is really Worthing's first medical officer of health, the borough heretofore having been included in a combine including the whole of West Sussex. East Preston is the union district in which Worthing is situated. Dr. Wilshaw is at present deputy medical officer of health of Southport.

The Hunterian Lectures

ON

THE ANATOMY OF THE LONG BONES RELATIVE TO CERTAIN FRACTURES.

Delivered before the Royal College of Surgeons of England on March 9th and 11th, 1908,

BY RALPH THOMPSON, CH.M. VICT., F.R.C.S. ENG.,

ASSISTANT SURGEON, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA; DEMONSTRATOR OF ANATOMY, GUY'S HOSPITAL; HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE II.[1]

Delivered on March 11th, 1908.

MR. VICE-PRESIDENT, LADIES, AND GENTLEMEN,—It is evident that in fractures of the neck of the thigh bone a knowledge of the internal structure of the upper end of the femur is essential to a complete understanding of their anatomical cause and results. This is no less necessary with regard to other bones, and if some of the points which it is proposed to consider be, on the one hand, self-evident or, on the other hand, familiar, their mention will be at once excused, as he who sets out to discuss questions of this nature must of necessity discuss these points; in the first place, the way in which the main pressure is transmitted through the bones of the limbs must be stated clearly; in the second place, the influence of this pressure upon the internal structure of bone must be shown; and, in the third place, the influence of these lines of pressure upon the lines of fracture which occur in various sites must be demonstrated.

COLLES'S FRACTURE.

The bones of the forearm may first be considered with especial reference to the exact anatomy of Colles's fracture. When a coronal section of a radius which has been macerated is examined pressure lamellæ will be found to pass up the bone from the lower articular surface in two main bundles, the adjacent parts of which interlace with each other below. One series passes into the inner side of the bone and another series into the outer, of which series perhaps the latter are better developed. Both these series lie practically at right angles to the articular surface which is, of course, curved. When a sagittal section is examined two series of lamellæ may be observed, the first a small series passing from the anterior half of the articular facet of the lower end of the radius to the anterior surface of the bone; these are hardly longer in their greatest length than half an inch. The more important series pass from the posterior half of the carpal articular facet for a distance in their greatest length of nearly one and a half inches. These join the posterior surface of the

---

[1] Lecture I. was published in THE LANCET of April 18th, 1908, p. 1127.

Physical condition on admittance to hospital.—The patient was very pale [Extremely obtrusive anæmia.—F. J. S.] and wasted, was incoherent in his speech, and could only understand and answer the simplest questions. He also suffered from hallucinations, such as believing that his wife was waiting for him, &c. Every movement was tremulous, as was also his speech. The mouth and tongue were parched and coated with a dry brown fur. The breath was rather foul and the skin was dry. The lungs were clear. The apex beat of the heart was in the fifth space, four and a half inches from the mid-sternal line. At the apex a systolic murmur could be heard which did not obliterate the first sound. At the aortic and pulmonary areas the first and second sounds could be heard. The spleen could be just distinguished below the costal margin. There was no tenderness of the abdominal wall, which was somewhat flaccid and showed a few spots not disappearing on pressure. The temperature was 103° and the pulse was 112. The urine showed no albumin, but mucus and urates. The result of an enema contained no solid bodies and was of a general soft consistency hardly fluid; gamboge in colour; it failed to give the guaiacum reaction. Microscopically, pus corpuscles could be distinguished in a rather large amount of epithelial débris. On Dec. 4th some blood was drawn off from a vein. With a sample of this Widal's test was performed. The result was very doubtful. "A dilution of 1 in 100 showed some clumping but not complete in 30 minutes." With the remaining quantity a blood culture was made; the report on this was, "grew a pure growth of influenza bacilli." Ehrlich's test with the urine also gave a negative result. An estimation of the hæmoglobin gave an approximate result of 70 per cent. A few days later a blood count showed the red blood corpuscles to be 1,830,000 and the white corpuscles 6300 (approximately). The blood pressure was 115 millimetres of mercury (taken on Dec. 9th.) The patient showed no inclination for food of any description and had to be cajoled into taking any nourishment.

Progress of the case.—On Dec. 9th it was noted that the lower half of the right lung, both behind and in front, was somewhat dull. Breathing sounds were faint on both sides. By the 11th the spleen was certainly impalpable and on this date also the murmur seemed diminished. On the 13th "there is a loud mitral systolic consisting of (1) a whistling and (2) a rough part" (F. J. S.). This murmur seemed to gradually diminish until by the 20th it was appreciably reduced. The urine showed at first no trace of albumin. On the 6th, however, a trace appeared, and on the 20th there was in a test-tube about one tenth. The temperature was between 100° and 101° up to the 10th; subsequently it dropped to between 99° and 98° from the 14th to the 18th, and on the 20th it was 98·6°. The pulse was on admission 112; on the next day it was 125, and then between 110 and 120 gradually dropping to 104 on the 10th and touching 100 on the 17th and 20th. The further progress of the case offered no point of special interest, and the patient died quietly on Jan. 1st, 1908.

Post-mortem appearances.—Dr. H. M. Turnbull has made a very long report in the hospital records which, from a clinical point of view, offers very few points of material changes. The obvious naked-eye findings were: verrucose endocarditis of mitral valve, large septic infarct in the spleen, pericarditis and pleurisy with some serous effusion, peritonitis with slight sero-purulent effusion, large, pale, mottled kidneys, and the brain somewhat atrophied. Dr. Turnbull's full report is mainly concerned with showing that there was no local focus (such as middle ear, lungs, &c.) to account for what was obviously a case of blood infection with vegetative endocarditis. Sections of most of the organs were cut and stained and showed large numbers of the bacilli found by Mr. F. W. Twort, assistant bacteriologist to the London Hospital, still *in situ*.

Mr. Twort kindly supplies the following notes on the bacteriology of the case:—

Blood cultures were taken on Dec. 4th, 10 cubic centimetres of blood being withdrawn from the median basilic vein in a sterile syringe and distributed into ordinary, glycerine, and glucose broth, and into milk; placed at 37° C. all cultures grew in 48 hours minute bacilli which were easily decolourised by Gram's method and were non-motile. Subcultures on to agar grew in the presence of human blood but failed to grow on gelatin at 20° C. or on any of the ordinary media at 37° C. in the absence of blood. The cultures died out before the bacillus could be induced to grow on the ordinary blood-free media. The morphological characters of the bacillus were typical of influenza and its behaviour on artificial media leaves no doubt that the organism was the true influenza bacillus.

Cases of fatal endocarditis from influenza are still sufficiently rare to warrant the publication of any definitely proved case which this claims to be but I think that it has a further special interest of its own as suggesting the query in the title of this communication—what was the nature of this man's previous illnesses and what were the relations between them and his last fatal illness.

Bacteriology has quite recently introduced us to so-called typhoid carriers—i.e., persons who carry about with them (possibly or probably in their gall-bladders) typhoid bacilli potentially active in that they can infect other people or articles though they do not cause symptoms of typhoid fever in their hosts that harbour them; my suggestion is that it is possible that something of a similar nature may be true of influenza, and I would hint at the possibility of it also being true of all our so-called zymotic diseases.

Taking my case as it stands we may note that eight years ago was about the time when our major epidemic of influenza was dying out and probably the statement is correct that the patient then had the disease; about then, and even now, it is probable that a good deal is called influenza which is not so, but the history given fairly well corresponds to what we know of a severe attack. Three years ago influenza was not so fashionable as a diagnosis, and he is then said to have had typhoid fever, but I would draw attention to the very striking resemblance in the description of the two illnesses, the duration and the prolonged subsequent debility are identical, and surely there is something a little more than a possibility that it was another attack of active influenza. There may be a bacteriological difficulty in admitting that it was so, as I suppose he would have had to transfer his bacilli (for him inactive) to a second host or to multiple hosts and they, or one of them, would have had to re-infect him with a generation which had been strengthened by transmission through other hosts so as now to be active for mischief even with him. Of the rash about a year ago we have no further particulars, but we are well acquainted with a variety of rashes appearing with influenza so that the possibility of this being a third attack is not to be excluded.

Now of the last fatal illness of this patient we have a complete history, and such information as amounts to a mathematical demonstration that it was due to the influenza bacillus, notwithstanding the fact that it was called typhoid fever and did present what are commonly accepted as the principal features of that disease. It began with severe headache and bronchitis and diarrhœa, and with these were associated an enlarged spleen and a rash said to be that of typhoid fever. As no bacteriological test (Widal) was made at that time one cannot wonder at a diagnosis of typhoid fever being arrived at. I must claim the credit of having said when I first saw him in hospital, "This is not typhoid fever, whatever else may be causing the typhoid fever state of illness," a clinical impression that was soon confirmed by scientific tests negative of typhoid fever and positive of influenza.

I cannot help feeling that calmly to assume that the attack three years ago was also influenza is going a little farther than one is perhaps justified in doing, but considering the absence then of any scientific test and the very positive likeness of the last illness to typhoid fever, it seems to me that we are not doing any violence to evidence by such an assumption, and if the assumption happen to be correct the sequence of events in the last eight years seems to be very highly suggestive of the idea of influenza carriers on a par with the typhoid ones and resembling the known cases in which nurses and others in fever hospitals carry in their throats undoubted diphtheria bacilli without suffering from the active symptoms of the disease.

The weak link in the chain of evidence is, of course, the absence of any proof that my patient was a centre whence infection of influenza spread to his neighbours, a link which, considering the very wide distribution of influenza outbreaks, we can hardly expect to be able to supply, but I think the history is very suggestive; and, indeed, when one comes to think of it the idea of "carriers" has an inherent probability to which the present state of bacteriological research seems to lend a good deal of support. Whether the idea, if true, may have practical bearings in the direction of preventing outbreaks of our endemic fevers would seem to depend upon the chance of detecting such carriers and then the chance (probably a small one) of disinfecting them; these are points upon which it is at present impossible to offer any opinion but it is to be hoped that bacteriologists will not lose sight of the question.

Dr. W. Bulloch has kindly given me the following references to previously recorded cases of fatal influenzal endocarditis:—

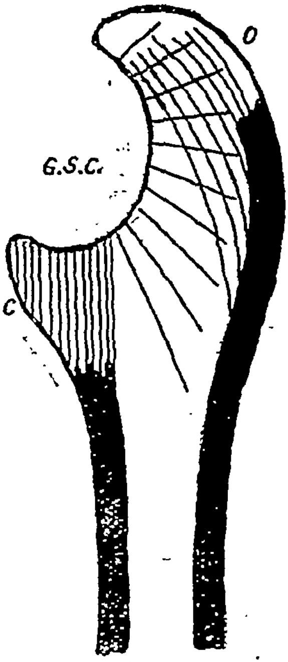
Schlagenhaufer: Ein Fall von Influenzaendocarditis der Aortenklappen und des offenen Ductus Botalli. Zeitschrift für Heilkunde, 1901, vol. xxii. T. J. Horder: Bacillus Influenzæ as a Cause of Endocarditis, Transactions of the Pathological Society of London, 1906, vol. lvii., p. 58. Presslich: Einiges über Endocarditis bei Influenza, Wiener Medicinische Presse, 1905, No. 2–3.

Harley-street, W.

ROYAL SANITARY INSTITUTE.—The ordinary general meeting of this institute was held at the Parkes Museum on April 15th, Mr. H. D. Searles Wood being in the chair. The annual report of the council for the year, showing the satisfactory general progress which the institute has made in carrying out the objects for which it was founded, was adopted, and Dr. Bushell Anningson of Cambridge; Dr. J. Spottiswoode Cameron, medical officer of health of Leeds; Mr. C. H. Cooper, borough surveyor of Wimbledon; and Mr. E. G. Mawbey, borough engineer of Leicester, were added to the council for the ensuing year. The meeting passed a vote of thanks to his Grace the Duke of Northumberland, K.G., for acting as President of the institute.

records at Guy's Hospital during the past five years it more frequently occurs than by other means—following upon a direct injury such as a fall or a blow upon the shoulder. Now, when a man falls upon his outstretched hand with the upper limb either in the abducted position or the adducted position the fracture is said to be due to indirect violence. If, however, the man falls upon his shoulder the fracture is said to be the result of direct violence. The fracture more often occurs in people of middle age or in older people. Fracture of the surgical neck of the humerus may occur in young children, as in a girl under the care of Mr. C. H. Golding-Bird who kindly allowed me to take charge of the case. Those fractures of the *surgical neck* of the humerus occurring in young people must be carefully distinguished from separation of the upper epiphysis of the humerus, as the prognosis is materially affected by this diagnosis. Fracture of the *surgical neck* of the humerus in young people if properly treated need not lead to shortening of the limb. Separated epiphysis, however well treated, may do so. The line of the upper epiphysis of the humerus is about half an inch above the surgical neck of the humerus.

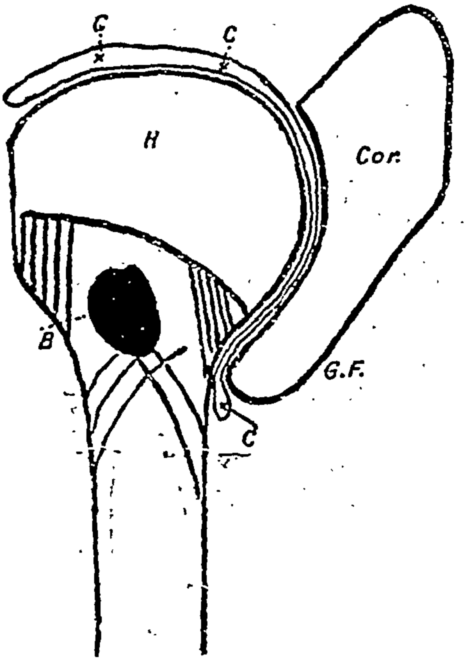
FIG. 15.



Upper end of ulna. O., Olecranon process. C., Coronoid process. G. S. C., Great sigmoid cavity. Scale life size.

I shall now refer to a coronal section of the upper end of the humerus and indicate the changes which take place in it with advancing age. From the upper part of the inner surface of the shaft of the humerus vertical lamellæ may be observed passing up into the head and reaching the articular surface. These lamellæ are supplemented by other lamellæ which, starting in the same region, pass into the head further out than these lamellæ and also into the great tuberosity. A well-marked series of lamellæ pass into the head from the outer surface of the shaft as well as into the tuberosity. These last series may be considered to be tension lamellæ, the first *series as* pressure lamellæ, and they are exactly analogous to those seen in a coronal *section* of the upper end of the femur. Fat is also deposited where the lines of tension and *pressure* are *less* useful, as in the femur, and a definite fatty patch is formed in some *cases as much* as one inch long by half an inch broad, the centre of which is just opposite the *surgical* neck of *the* humerus. This fatty patch is one cause, so far as the internal structure of the bone is concerned, of fractures in this region. I must now direct your attention to this specimen of a formalin-hardened shoulder-joint, in which the arm was nearly brought down to the side but not completely or over-adducted. (Fig. 16) The shoulder-joint will be found to be prolonged upon the surface of the upper end of the humerus so that there is a pouch of synovial membrane bounded by the capsule of the joint. This pouch is triangular with its apex downwards and is about three-quarters of an inch deep. Save at its upper part it is not, so far as my dissections give *information*, attached directly to the neck of the humerus, but can be easily stripped off it except at its upper part. Now although this pouch of the shoulder-joint may be developed in connexion with the very loose capsule of the joint and *is really merely* a fold of this capsule and synovial membrane, it has a very definite and useful function. When the arm is fully adducted to the side the inferior lip of the *glenoid* fossa comes into forcible contact with the surgical neck of the humerus.

FIG. 16.



Upper end of (H.) humerus and scapula. Cor., Coracoid process, showing parts concerned in fracture of the surgical neck of the humerus. C. C. C., Cavity of shoulder-joint. B., Fatty patch in bone. G.F., Inferior lip of the glenoid fossa. Scale life size.

In the normal scapula placed in the correct position the inferior lip of the *glenoid fossa* is much more prominent than the upper lip owing to the oblique position of the glenoid fossa. In the adducted position of the upper limb, then, the inferior lip of the glenoid fossa is in contact with the surgical neck of the humerus. Now in this adducted position flexion and extension of the shoulder-joint are possible as well as internal or external rotation. The surgical neck of the humerus is thus moving in *various directions* upon the inferior lip of the glenoid fossa, hence the prolongation downwards of the synovial membrane and capsule of the shoulder-joint. Now if a scapula be examined *the* glenoid fossa will be found to be supported by well-marked pressure lamellæ passing *from* the articular surface of the fossa in two main directions, upwards and *inwards* into the coracoid process, downwards and inwards into the axillary border of the *scapula* and to its inferior angle. If the thin parts of the scapula be removed it will be apparent that there are three bars supporting the glenoid fossa or head of the scapula. *First*, the axillary bar—i.e., the strong axillary border; secondly, the *coracoid process* or coracoid bar, which passes upwards and inwards from the glenoid fossa and may be considered to terminate in the thick and massive proximal part of the *coracoid* process; and thirdly, the spinous bar, which passes almost directly inwards from the glenoid fossa and forms the base of the spine of the scapula. This is *much* less strong than the axillary or coracoid bars. Now the lamellæ which pass from the lower *half* of the glenoid fossa and which are displayed in this representation of a *coronal* section of the scapula are very prominent and strong and give considerable support to the inferior lip of the glenoid fossa which comes, as we have seen, into contact with the surgical neck of the humerus. When, therefore, a man falls either directly on to his shoulder or with his *deviation* for this series is 6·6 per cent., as opposed to 7 per cent. for the whole mass of our statistics. Further, it has occurred again and again that a result has been doubted by the observer on the score of bias, and has only been re-affirmed by a renewed count where this supposed source of error has been excluded.

3. *The variations of tuberculous sera are large.*—We have given our reasons for believing that normal serum varies much less than Dr. Kjer-Petersen's figures might indicate. We now proceed to the consideration of the sera of tuberculous patients. We have been able to collect 931 observations on 319 patients who had not been inoculated. The *standard deviation* from the normal mean is 0·252, a value greatly exceeding that found for normal sera (0·07). The observations are distributed as follows, and agree very nearly with the "normal curve of error."

TABLE II.

Within	0·126	of the normal mean	374	=	402	per mille.
"	0·252	" "	670	=	720	"
"	0·504	" "	885	=	951	"
"	0·756	" "	922	=	990	"
"	1·000	" "	931	=	1000	"

The opsonic indices of tuberculous patients vary, therefore, three or four times as widely as the indices of normal sera. Thus much we can conclude at present; but with increased accuracy of technique it may in the future be shown that the variations of normal sera are much less than we have here assumed, while the correction introduced by such improvements would have little effect on the larger value we have found for the variations of tuberculous sera.

Let us see to what corrections this figure is liable. In a minority of these determinations only 50 cells were counted, but this can only have altered the results very little. The mean counting error cannot be greater than the *standard deviation* of our observations of normal sera. This was 0·07, 100 cells being counted. For counts of 50 cells the mean error will consequently not exceed 0·10. Applying this maximum correction to the whole number of observations, and also allowing for the mean error of the estimation of unity, the *mean variation* of pathological sera is only reduced from 0·252 to 0·226. Such an alteration is trivial and without effect on the validity of our argument.

4. *Some general considerations.*—If statistical methods are to be applied we have shown that numbers are not wanting to support the truth of our conclusions. Further, Dr. Kjer-Petersen's experimental methods are open, even at this distance, to serious criticism. First, we suspect that a certain number of infected individuals may have been included among his 48 normals. In this laboratory, among those who have from time to time offered their blood as a standard in opsonic estimations, tubercle has been diagnosed seven times. The diagnosis rested in the first instance on variations of the tuberculo-opsonic index. In four of these cases clinically recognisable tuberculosis subsequently declared itself.

Dr. Kjer-Petersen also delegates the counting of his slides to a second observer, and in so doing throws away a valuable check on the previous stages of the technique; a high level of perfection in making and staining films is only to be maintained by that constant self-criticism which is incidental to the actual counting of films one has oneself prepared.

CHRONIC POLYCYTHÆMIA.

BY EDMUND CAUTLEY, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE METROPOLITAN HOSPITAL AND THE BELGRAVE HOSPITAL FOR CHILDREN.

THE following case of polycythæmia is worthy of record although the details do not add anything definite to our knowledge of the condition. The patient was under observation for a long time and a post-mortem examination was obtained. Vaquez first described a case in 1892 and ascribed it to congenital heart disease, until a necropsy in 1895 enabled him to exclude such a cause. Dr. J. W. Russell[1] claims that he described the first case[2] in England under the title of "An Unexplained Condition of Chronic Cyanosis." The patient was under the care of Dr. Robert Saundby, who gives a further description of in a paper on the subject.[3] Dr. Saundby gives a full bibliography of recorded cases and mentions that Dr. F. Parkes Weber first named the affection "chronic splenomegalic polycythæmia." Since then a case in a man, aged 67 years, has been recorded by Pethybridge,[4] and in a woman, aged 68 years, by McQuitty.[5]

The patient, a man, aged 47 years, was admitted into the Metropolitan Hospital under my care on Sept. 30th and was discharged on Oct. 25th, 1905. According to his past history he had an attack of hæmoptysis in 1887, influenza in 1893, and pneumonia in 1901. He was an abstainer and denied lues venerea. For two months he had suffered from pain in the left side, difficulty in breathing, and constipation. He had had no cough. On examination he was found to be a healthy-looking man, with fresh complexion. His teeth were few and bad. The respirations were 34 and the pulse was 88 per minute. He had a subnormal temperature. The reflexes were normal. The heart dulness was diminished, the apex beat was normally placed, and the impulse was feeble. The liver dulness began at the lower border of the sixth rib. The left side of the chest was dull, below the level of the seventh rib in the nipple line and the eighth rib in the mid-axillary line, and the air entry was diminished. A tender lump was felt in the splenic region. It was shaped like the spleen and extended to within an inch of the middle line of the abdomen. It was continuous in dulness with the normal splenic dulness but was resonant over the lower part. There was much tenderness on palpation and the muscles were rather rigid. A diagnosis of perisplenitis and pleurisy with slight effusion was made. A blood examination made on Oct. 19th showed: red cells, 7,500,000; and white cells, 50,000. A week later the red cells were about the same in number and the white ones were 45,000. A differential count showed that the white cells were nearly all polymorphonuclears. The course of the illness was as follows. The spleen became much smaller and the tenderness disappeared. The pleural effusion cleared up slowly. The temperature was usually from a half to one degree below normal, the pulse-rate was from 72 to 88, the respirations were 24, and the urine was normal. The loss of weight was half a pound. On Nov. 15th the spleen was still palpable and the white cells numbered 39,000. He had been at work for about three weeks and came to the hospital on account of pain in the right side and slight hæmoptysis.

In 1906 the man was again an in-patient from April 8th to July 14th, being admitted for pains on and off in the legs, thighs, and shoulders. The floridness of the face was more noticeable and on questioning he stated that he had had it for about two years. The colour varied from deep redness to a cyanotic tint. The ocular conjunctiva was injected and the palpebral intensely red. The tongue was clean, dry, and very red, and he complained of thirst. The cardiac dulness was diminished, the apex beat was not felt, and the sounds were clear. The spleen could be felt just beneath the costal margin and was slightly tender. Posteriorly its area of dulness was increased. The liver was rather enlarged and tender. The pulse-rate was 80, the arteries were thickened, and the arterial tension was high. The blood showed red cells, 9,800,000; hæmoglobin, 110 per cent.; white cells, 82,000, chiefly polymorphs. The fingers were a little clubbed. His symptoms were limited to weakness, variable pains and shortness of breath, and coldness of the hands and feet. On April 19th there was no pain in the limbs. Some hepatic pain and tenderness were present. On the 23rd the blood showed: red cells, 10,000,000; hæmoglobin, 130; and white cells, 59,000; the specific gravity was from 1068 to 1070. The blood pressure was from 180 to 200 millimetres of mercury. The capillary reflex was 10. On May 6th clubbing of the fingers was more marked. The patient had complained of tenderness over the liver and spleen, occipital and frontal headache, and tender gums with slight oozing of blood. He was more cyanosed. The blood pressure was 160 millimetres of mercury. There was much albumin in the urine. On the next day he had pain in the right vastus internus. The knee-jerks were unobtainable and the plantar reflex was flexor in character. On May 10th the tongue was moist and had a whitish fur on it. The spleen was not palpable. The urine was acid, of specific gravity 1015, and contained much albumin. On the 17th the amount of albumin was reduced to a cloud and the specific gravity was 1013. The blood showed: red cells, 8,600,000; hæmoglobin, 150; and some normoblasts. On the 24th an attack of orchitis on the left side began and took nearly right angles. These individual lamellæ are arched so as form, as Professor Arthur Thomson points out, a series of othic arches. Internal to this portion of the bone the ompact tissue on the surface of the bone becomes much icker and the cancellous tissue is arranged in a series of ick and massive lamellæ running nearly parallel with the ain direction of the bone from without inwards and from e upper to the lower surface. The compact tissue of the wer surface is very much thicker than the upper. Very nall pressure lamellæ are developed in the ends of the bones rming the acromio-clavicular joint in contradistinction to e well-marked pressure lamellæ in the inner end of the ne. The arrangement, therefore, of the compact and ncellous tissue changes very materially in the region of the apezoid ligament. We may therefore fairly conclude that is only that part of the clavicle which lies internal to the apezoid ridge which transmits pressure to the trunk from e upper limb. This, then, is the reason of fractures being ore common, especially by indirect violence, in the middle ird of the clavicle than in the outer third. The outer art of the clavicle transmits but little pressure from the pper limb to the trunk.

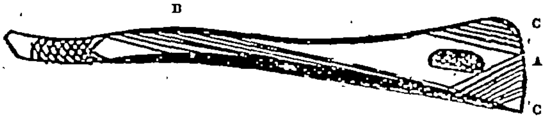
FIG. 17.



Longitudinal section of right clavicle showing its internal structure. A, Fatty patch. B, Main pressure lamellæ. C, C, Pressure lamellæ of sternal end. Scale, half life size.

The outer part of the clavicle is said to be more frequently roken by direct violence, but it is a relatively rare form of acture, and if we refer to the acromio-clavicular articula-on we shall, I think, understand the reason of this. etween the clavicle and the acromion process there is a iangular fibro-cartilage which diminishes the effect of a low struck upon the acromion process externally, but we ay well inquire here why is this fibro-cartilage triangular. lthough the articular surface of the clavicle which forms art of the acromio-clavicular joint is set obliquely to the haft, in other words, is bevelled at the expense of the under urface of the clavicle, we rarely find a corresponding obliquity, or rather bevelling, on the acromial articular surface. The upper surface of the acromion looks also outwards—the lower surface also inwards—so that the acromion is set at an angle with the clavicle open downwards. The clavicular surface of the acromion is not vertical but it is not obliquely set upon the acromion process but at right angles. The upper and lower edges are, in other words, square with the upper and lower surface of the acromion. The obliquity of the clavicular surface is less inclined from the vertical than is the articular surface on the acromion, and so an angle is left which is filled up by the triangular fibro-cartilage.

Another clavicle which I have sawn across shows a most interesting condition of affairs. Here I know that the coracoid process was in contact with the clavicle just in front of the conoid tubercle, a well-marked bursa intervening. There is a corresponding depression on the under surface of the clavicle just in front of the conoid tubercle, and when a section is made of the clavicle there is a solid bar of bone passing over the greater part of the thickness of the clavicle in this region—i.e., where the coracoid process impinged against it the lamellæ have disappeared as separate entities and the cancellous tissue is replaced by compact tissue. This clavicle, which was certainly actually resting upon the coracoid process, belonged to a man whom I found afterwards was a cab-driver. He therefore belonged to a class of men who are not accustomed to bearing heavy weights upon their shoulders; in fact, so far as my experience goes, they, as a rule, resent being asked to bear heavy weights on any part of their anatomy. It has been clearly demonstrated that pressure passing through the upper limb is transmitted to the trunk through the inner two-thirds or a little more of the clavicle. This has an important bearing upon fractured clavicle as regards the anatomical cause for it. All authorities are agreed that the most common position of a fracture of clavicle is in the middle third. Sir Frederick Treves and Dr. A. Keith say that fracture occurs most frequently at the outer part of the middle third of the clavicle. The relation which I have pointed out as existing between the clavicle, coracoid process, and trapezoid ligament explains the occurrence of the fracture in this region. The tension of the trapezoid ligament, the tendency of the coracoid to impinge against the clavicle, the intimate relation and strong attachment of the coraco-clavicular ligaments as a whole produce a bending of the clavicle in this position, and if the force be continued a fracture. I have here a specimen which I fractured experimentally and the fracture is in this position. The position of the fragments in cases of green-stick fracture would be interesting in this connexion. Fracture of the clavicle between the conoid and trapezoid ligaments is said to occur usually as a result of direct violence. Mr. Arbuthnot Lane, however, is of opinion that such fractures are frequently due to indirect violence—that is, by a blow upon the outstretched hand. Now with regard to the first statement, pathological specimens of fracture between the conoid and trapezoid ligaments are relatively rare, and this is not to be wondered at, for although the conoid and trapezoid ligaments may be separated from each other by a careful dissection—they are practically continuous, and it would require rather a precise and delicately balanced form of external direct violence to produce a fracture in this region.

With regard to the second statement I have, I hope, shown that when the blow is received upon the outstretched hand the coracoid process may impinge forcibly against the clavicle. If this be so, and we can scarcely doubt it, we have in these cases of fracture of the clavicle between the conoid and trapezoid ligaments the impinging force applied in this region. Here again, therefore, like the fracture of the surgical neck of the humerus, we have as it were direct violence applied from within. It is asserted that fractures in this region are never accompanied by displacement, that no displacement is possible. I have here a specimen of fractured clavicle in this region showing that considerable deformity may occur. There is not only displacement but impaction.

under the iliac fascia another opening was made through which further drainage was established. After this the temperature never rose above 99°, the wounds healed, and recovery was uneventful, except that for six weeks after operation the bowels were obstinately constipated, acting only after simple enema. However, during her last three weeks in hospital they acted regularly under the influence of a laxative iron mixture and the patient was discharged on Nov. 18th feeling quite well.

I think the case is rather interesting, first on account of the long history with these recurring attacks of appendicular colic; then the passage of a 1½-inch pin from the mouth to the appendix without giving rise to more serious symptoms than were present here, though undoubtedly possible, must surely be an uncommon occurrence. Again, at the junction of the appendix with the cæcum is a valve, and a much debated point is how far fæcal matter can penetrate into the appendix and how far it does so under normal conditions. This pin is an instance of a foreign body (most probably with some fæcal material) entering from the intestine which, according to our best authorities, is comparatively rare.

For permission to publish the above note I must thank Mr. A. B. Davies, under whose care the case was at Stroud Hospital.

NOTE OF A CASE IN WHICH A GALL-STONE FORMED ROUND A CATGUT SUTURE.

BY HAMILTON DRUMMOND, M.B., B.S. DURH.,
LATE HOUSE SURGEON TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

THE patient the subject of this note was first admitted to the Newcastle Infirmary in December, 1901. She was a stout woman, aged 48 years, with a history of severe attacks of pain in the right hypochondriac region of 29 years' duration. A diagnosis of gall-stones was made and on Dec. 7th, 1901, she was operated upon by Mr. Martin.

The gall-bladder was found to be enlarged and adherent about the neck. It was opened and found to contain bile and six stones (three-eighths of an inch by three-eighths of an inch) with facets were removed from the cystic duct. The common duct was then explored after separating adhesions and several stones were removed by incision. No other stones were discovered. The common duct was drained with rubber tube and no sutures were inserted. The gall-bladder was closed with through-and-through ordinary catgut and a layer of silk Lembert sutures. The hepatic pouch was drained from the posterior end of the incision and the rest of the incision closed with layers of catgut. The patient made a good recovery and was discharged with the incision perfectly healed on Jan. 7th, 1902.

On Sept. 25th, 1907, she was readmitted with a history of good health up to four days before admission when she complained of slight pain over the old scar on going to bed. The pain persisted next day but was not severe and allowed her to perform her household duties as usual. On the following day it suddenly became very acute and she felt sick but did not vomit. In this condition she was admitted into the Royal Victoria Infirmary some seven hours after the onset of the acute attack. On examination a distinct tender swelling was found in the region of the gall-bladder. A diagnosis of acute distension of the gall-bladder from impaction of calculus was made and an operation was decided upon. Mr. J. Clay made a longitudinal incision through the right rectus muscle over the swelling and the distended gall-bladder imbedded in dense adhesions was exposed. The adhesions were separated and the gall-bladder aspirated and several ounces of clear mucus were evacuated. After incision a large rounded stone was found wedged in the neck of the gall-bladder, which was very much hypertrophied, though the cystic duct opening was patent. The patient did well and went home quite healed on Oct. 11th, 1907. There was nothing unusual about the appearance of the stone, which was round and measured one and a quarter inches by three-quarters of an inch and weighed 80 grains. On attempting to section it the stone broke in layers, showing different strata, and in the centre, forming a nucleus, was a bit of catgut tied in double knot and loop, which was well preserved. The calculus was composed of cholesterin and bilirubin calcium.

There are other cases on record in which gall-stones have formed round sutures: for example, Mr. Sinclair White[1] exhibited a specimen at the Exeter meeting of the British Medical Association in which a gall-stone had formed round a catgut suture 18 months after operation. Dr. J. Homans[2] reports a similar case where three gall-stones had collected round a piece of silk 20 months after cholecystotomy; and Mr. J. Bland-Sutton[3] in his book on gall-stones quotes an interesting experiment on a dog, where, after five months, two calculi formed round a thread which was suspended and allowed to float freely in the gall-bladder.

I have to acknowledge my indebtedness to Mr. Martin and Mr. Clay for permission to publish the above note.

Newcastle-on-Tyne.

NOTE ON A CASE OF DISSECTING ANEURYSM OF THE THORACIC AORTA ULCERATING INTO THE PERICARDIUM.

BY THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

THE patient, a man, aged 52 years, was admitted into the Royal Victoria Infirmary, Newcastle-on-Tyne, under my care on Dec. 24th, 1907, suffering from pain in the left side of the chest and the left leg. When at work that morning he had been suddenly seized with pain in the left chest which was so severe as to cause him to fall. He also vomited. Shortly after his admission into the infirmary he again vomited. The pain in the chest persisted from the time of his arrival at 8 A.M. until midday. On physical examination nothing was detected in the lungs. No murmurs were heard over the cardiac area. There was just the slightest displacement outwards of the apex beat. Towards the afternoon the patient seemed to rally considerably and to lose much of his pain. He was able to see his wife and to converse with her. At 5 P.M. he became suddenly ill; his breathing became laboured and difficult, and laying back his head on the pillow he suddenly expired.

At the necropsy, which was made by Dr. W. E. Hume, it was noticed on removal of the sternum that the pericardial sac bulged, and on opening it that it contained, in addition to blood-stained serum, 10½ ounces of blood-clot. The surface of the right auricle of the heart was granular and chocolate-looking. The heart itself was found to be healthy; there was neither hypertrophy nor dilatation of its cavities. A longitudinal tear about three-quarters of an inch in length was found in the aorta, commencing about a quarter of an inch above the aortic cusps, and involving the inner and middle coats of the vessel. These two coats of the aorta were separated from the external sheath throughout the whole of the ascending, transverse and descending portions of the arch, as well as at the openings of the innominate, the left carotid, and the left subclavian arteries. The space thus formed was filled with blood-clot. At the junction of the adventitia and the pericardial sac the surface was blood-stained. Here a leakage had occurred through a small ulcer in the external coat of the aorta. The interior of the aorta was atheromatous in places. The lungs, the liver, and the spleen were normal. One kidney showed a scar the seat of an old gumma with surrounding fibrosis. Below the diaphragm there was no separation of the coats of the aorta.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Fatal Lymphocythæmia in Early Life.—Multiple Rheumatic Nodules in an Adult.—Right Hemiplegia with Optic Atrophy.—Exhibition of Cases.

A MEETING of this section was held on April 10th, Sir THOMAS BARLOW, the President, being in the chair.

Dr. J. GRAHAM FORBES and Dr. F. S. LANGMEAD communicated a paper on Fatal Lymphocythæmia in Early Life based on 12 cases. Dr. Forbes said that the ages of the patients ranged from seven months to 11 years, ten being under four years. The disease as exemplified by these cases was of indefinite onset, with a history of increasing rom this time up to October, 1905, he had at least ven attacks, but only two of them were severe, the mainder only lasting about a week. He remained well ntil August, 1907, when the worst attack I have attended im in commenced and lasted till the middle of October. p to this attack I had always been able to keep the pupil ilated and recovery took place without damage to sight, ut this time the inflammation was most violent, blood-essels gave way, and he had hæmorrhage in the anterior hamber; all the mydriatics I used caused irritation; here were much pain and frequent rise of tension. I as unable to keep the pupil dilated, extensive synechiæ ormed, and the pupil became occluded; vision was reduced reading J. 12 c. + $\frac{1\cdot25 \text{ cyl.}}{4 \text{ sph.}}$; by the beginning of ecember it had improved to J. 4 and $\frac{6}{12}$ with correction. n the 20th of that month I performed iridectomy and he as since made good progress and his sight is improving. t is worthy of note in this case that up to the time I first aw him the right eye was the one almost always attacked nd that after the iridectomy it was slightly inflamed on two ccasions only; all the severe attacks for which I treated he patient being in the left eye alone, which had been but rely attacked before. It would seem almost as if it would ave been well to have let the damaged eye alone and allow to suffer instead of its sound fellow.

[2] Annals of Surgery, 1897.

[3] Bland-Sutton on Gall-stones and Diseases of the Bile-ducts.

CASE 3.—The patient, a man, aged 37 years, was first een in April, 1906. He had severe iritis in the right eye; his was the first attack. He had had gonorrhœa shortly efore and besides the iritis, complained of pain in the oints. The iritis lasted about a month and I did not see im again till Dec. 6th of the same year when he had quite ecovered. On Dec. 20th he started a fresh attack which asted some weeks. I did not see him again till February, 1907, when he had quite recovered from the iritis, but had gleet and complained of pain in his joints. He has got over his two attacks without the formation of synechiæ, but I suspect that this is only the beginning of his troubles. I have strongly advised iridectomy, but up to date (January, 1908) he has not consented to have the operation done.

Treatment.—The treatment of this form of iritis is most unsatisfactory. Mydriatics irritate and rise of tension is of very frequent occurrence, consequently they must be used with caution. I have used atropine, *daturine*, *homatropine*, hyoscyamine, and scopolamine in solutions of varying strength and in ointment, but have had difficulties with all of them. If the pupil can be got to dilate fully at the beginning of an attack before much congestion has taken place it is a point gained, but even then there is a great tendency to contraction as the case progresses, and we may experience great difficulty in keeping it dilated, which may be still further increased by a rise of tension.

Heat applied in the form of bathing with simple hot water, solutions of boric acid or other antiseptics, decoction of poppy heads or belladonna lotion, used as hot as can be borne and constantly applied for from 10 to 20 minutes several times in the 24 hours, or by Leiter's coil, electric coil, or heated pads of cotton wool, and covering the eye with hot compresses are all useful, especially in cases where pain is a marked symptom or where there is increase of tension. Blisters I do not care about. Leeches I believe in; three or four applied to the temple often cause a marked decrease in congestion and may act almost like magic in relieving pain.

Before going further let me sound a note of warning against the use of cocaine and allied substances and also of adrenalin. They are constantly ordered to be used frequently and the treatment is flattering both to surgeon and patient, for they reduce vascularity and relieve pain, but their after-effects are positively harmful, for they cause paralysis of blood-vessels and thus add fuel to the fire which they are intended to extinguish. I have no hesitation in saying that none of these should ever be used except for purposes of local anæsthesia and prevention of bleeding during an operation or for the examination of painful or sensitive parts.

The constitutional treatment I have employed has been free purgation and washing out the system by copious draughts of hot water; mercury, iodides, salicylates, and quinine; opium, bromides, aspirin, and hyoscyamus, internally, or hypodermic injections of morphine to relieve pain; visits to Aix-les-Bains, Homburg, Harrogate, Buxton, Bath, and other spas between the attacks; limiting as far as possible the consumption of alcoholic drinks and avoidance of all foods which the patient knows upset his digestion. I cannot say that I am satisfied with the results of the treatment I have adopted.

Salicylates generally I do not think do any good but aspirin relieves pain. Iodides in my experience depress the patient and do no good. Mercury administered by the mouth or by inunctions I believe in, especially in cases where there is exudation, and I am very strongly of opinion that a visit to one of the spas has warded off an attack. Of serum treatment I have no experience but can believe that it might do good. I am not certain about iridectomy but should recommend it in all cases where recurrences are frequent; in cases of excluded or occluded pupil and *bombé* iris its performance is imperative.

Remarks.—Syphilis is responsible for a large number of the ills to which flesh is heir, but I am not certain that gonorrhœa does not run it pretty closely; at any rate, a large amount of misery and suffering may be caused by it beyond the subject of this paper. We have only to look at the multitude of persons blind or partially so from ophthalmia neonatorum and gonorrhœal ophthalmia later in life. Then there are the pain and inconvenience of its initial stage, and if it ended there no particular harm would be done, but it does not. Urethral stricture with all its attendant complications would scarcely exist if it were not for gonorrhœa. Men crippled and incapacitated by gonorrhœal rheumatism, women with health ruined from tubal and uterine affections or dying from septic peritonitis, are a few of the evils which result.

The question which must present itself to all well-balanced thoughtful minds is, Why should these things be? Gonorrhœa and syphilis are preventable diseases and can be stamped out. Why is this not done? Is it from motives of morality—in this case synonymous with hypocrisy—cant, false modesty, fear of interference with the liberty of the subject, or what? Whatever may be the cause the fact remains that men and women are allowed to go about at will suffering from highly contagious and easily communicable diseases without let or hindrance and this in an age of preventive medicine. Venereal disease should be prevented and I would suggest that, as a beginning to the attainment of this much-to-be-desired object, gonorrhœa and syphilis, whether occurring in men or women, should be placed on the schedule of notifiable diseases.

Brook-street, W.

THE INFLUENZA BACILLUS AS A CAUSE OF FATAL ENDOCARDITIS AFTER EIGHT YEARS?

(AN INFLUENZA-CARRIER?)

BY FREDK. J. SMITH, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

To Mr. Candy, the ward clerk to the case, I am indebted for the following details of the patient and his last illness.

A man, aged 45 years, married, was admitted to the London Hospital on Dec. 2nd, 1907, in a condition supposed to be a relapse from typhoid fever.

Family history.—The patient has been married 18 years and has had four children. Three have died from diphtheria, bronchitis, and whooping-cough with congestion of the lungs, respectively. One child alive is only eight months old and healthy. The last of the three to die died eight years ago, and the patient has worried over this ever since. The patient's father, aged 74 years, is still living and healthy though he suffers from melancholia, but his mother died 36 years ago from typhus fever.

Previous history.—The patient is a spring-maker in the Great Eastern Railway works. The work is rather hard; he is in the habit of getting up at 5.30 A.M. and knocking off at 5.30 P.M. He drinks about two glasses of ale a day but takes tea only in small quantities. Eight years ago he had influenza followed by nervous debility; for this he was attended by the medical officer of his club and had a nurse at home; the illness lasted six months. Three years ago he had an attack of enteric fever which lasted six months; for this he was also treated at home. One year ago a rash appeared and the patient was in bed for 14 days.

History of present illness.—The attack began two months before admission (approximately Oct. 6th), the symptoms being severe headache, bronchitis, light loose stools, enlarged spleen, typhoid spots, and a temperature ranging from 101° to 99° F. For about two months before this the patient had lost his appetite and had complained of a tired feeling, with pains in the joints, especially in the ankles. These disturbances were accompanied towards the end of this period with fits of shivering, thirst, and inability to speak, this inability to speak lasting perhaps 30 minutes. After being in bed for three weeks (approximately Oct. 27th) the temperature fell to normal and ten days later (Nov. 6th) the patient got up. The temperature rose at once. Ten days later (Nov. 16th) a cardiac murmur was first heard; the typhoid spots were well marked; there was some delirium and slight sweating.

Dr. **NORMAN MOORE** showed a case of Myxœdema with Optic Atrophy. The patient was a man, aged 44 years, who was admitted to St. Bartholomew's Hospital on Feb. 7th last suffering from blindness and lethargy. He was first conscious of defective sight in his left eye in September, 1906, and in his right eye in June, 1907. He was a waiter and realised his defect of sight one day when he swept all the glasses off a table with the crumbs. His sight was a little better in the summer. On admission he was very drowsy and usually did not answer questions until after a long interval but now and then became so talkative that it was difficult to stop his flow of conversation. His eyes were kept half open or shut. The thyroid gland could just be felt. His complexion was pale. The skin was dry and thick all over, looking œdematous but without pitting on pressure. The mucous membrane of the mouth was thickened. The fingers were thick and there was tremor of the hands. The temperature was subnormal or normal. The knee-jerks were exaggerated and ankle clonus was present. Both optic discs showed atrophy, the left much more than the right. The visual field was not markedly contracted, but slightly so on the nasal side. He could perceive light with his left eye and could count objects with his right. After continued administration of thyroid extract his lethargy and abnormal mental state have disappeared, and he can walk well and has no tremor of his hands. He speaks of his left eye as blind, but can use the right better. The discs show no change.

Dr. **PARKES WEBER** showed a case of Œdema of the Hands and Feet with mediastinal affection. He said that the patient, an unmarried woman, aged 21 years, was admitted into the German Hospital on March 23rd last with great œdematous swelling and cyanosis of the hands and feet. The œdema was symmetrical; in the lower extremities it extended upwards as far as the knees and in the upper extremities to about the middle of the forearms, but the upper limit was not sharply defined in either extremities. The swelling had commenced to appear gradually in the feet about five or six weeks, and in the hands about three weeks, before admission. There was no œdema of the face or loins or elsewhere in the body. The patient said that she had previously enjoyed good health and was not aware of having anything else the matter with her. Examination of the thorax, however, showed dulness with diminished breath sounds and voice sounds over the lower part of the left anterior and axillary regions, up to the second rib in front, and up to the sixth rib in the middle axillary line. The upper part of the dull area was separated by about half an inch from the left border of the sternum. There was some impairment of resonance over the left infrascapular region. Vocal vibrations could be felt over the right front but not over the left front. There were no pulmonary adventitious sounds anywhere. The upper part of the left lung and the whole of the right lung appeared normal. The apex beat of the heart was in the normal situation but the cardiac dulness extended rather too far to the right; there was no evidence of valvular disease. Roentgen ray examination showed an extensive shadow on the left side of the thorax which corresponded to the abnormal area of dulness and was separated by a fairly sharply defined, dome-shaped border from an upper normally clear area. The heart shadow, which was not separated from the abnormal shadow, extended rather too far to the right of the sternum. There was slight anæmia. The superficial lymphatic glands were not enlarged. The thyroid gland was apparently of natural size. There was no paralysis of either vocal cord. The pupils were equal and reacted naturally to light and accommodation. The knee-jerks were very active, of the "trepidation" or "vibratory" type. There was no ankle-clonus and the plantar reflexes were not obtained. The radial pulse, usually about 100 to the minute, was regular and equal on the two sides and of low pressure. The temperature varied between 99° and 101° F. There was no cough or expectoration or history of hæmoptysis. The respirations were 30 to the minute. There had been no pain anywhere except a little when the feet were greatly swollen and the skin was very much stretched. The swelling, and especially the cyanosis, of the extremities had greatly diminished on rest in bed.

Dr. **PARKES WEBER** also showed a case of Hæmangiectatic Hypertrophy of the Foot, possibly of spinal origin. He said that the patient was aged 19 years and that his left foot was decidedly larger than the right and of a red or bluish-red colour as if turgid with blood. The skin over the part of the foot was closely studded with small venous loops (varices), as in a lesser degree was the skin over the knee-cap. The calf muscles and other muscles of the leg were about equally developed on the two sides, but there was considerable wasting of the left thigh and buttock and the left hip-joint was ankylosed. The pulsation in the dorsalis pedis artery was well felt in both feet. There was no anæsthesia and the reaction of the muscles to galvanism was normal. There was considerable kyphosis in the dorsal region of the spine. There was no evidence of any disease elsewhere in the body. Radiograms showed that the hypertrophy of the left foot was practically confined to the soft parts and that there was bony ankylosis of the left hip-joint (of doubtful origin). The history was that about two years ago the patient complained of pain in the back of the left thigh. He was at first treated for sciatica and was afterwards supposed to have hip disease and wore a Thomas's splint for 18 months. The hæmangiectatic hypertrophy of the left foot and the wasting of the thigh muscles had developed during the last two years, but the kyphosis of the dorsal region existed to some extent previously, though it seemed to have increased during the last two years.

Dr. **DAVID WALSH** showed a case of Spurious Acromegaly in a patient suffering from exophthalmic goitre associated with a congenitally high forehead. The patient was aged 35 years and for five years had been under treatment for recurrent patches of alopecia areata of the scalp. After a severe mental shock at Christmas, 1907, the patient developed symptoms of exophthalmic goitre. The face was suggestive of acromegaly but the appearances were similar in a photograph taken 18 years ago. The patient had a congenitally high forehead, a condition present in every one of a consecutive series of 35 cases of exophthalmic goitre. This congenital sign might be described as a band of baldness or semi-baldness of variable character stretching across the frontal region of the scalp, with a further triangular area or bay projecting backwards at each end. Sometimes the band was outlined by a thin pencil of hair showing where the hair should have reached in normal conditions of growth. It was suggested that this congenitally high forehead was connected with a peculiar temperament—"potential exophthalmic goitre," and in several cases exophthalmic goitre had actually developed under observation. As regards the resemblance to acromegaly the features might perhaps be of a reversionary type.

Mr. **HERBERT TILLEY** showed a case illustrating the result of operative treatment for Chronic Bilateral Empyema of the Frontal, Ethmoidal, and Sphenoidal Sinuses. The patient, aged 35 years, had suffered for two years from a profuse, purulent, offensive discharge from both nostrils, associated with a feeling of "tension" in the lower central region of the forehead. It was ascertained upon examination that pus was being discharged from all the sinuses and radical operations had been performed upon the antra only in May, 1907, by another surgeon. The discharge continued freely from the higher sinuses, and when it was found that free irrigation failed to check the flow radical operations upon the fronto-ethmoidal and sphenoidal sinuses were carried out. On Feb. 12th Killian's radical operation was performed on the right side and the sphenoidal sinus was also opened. On March 4th an incomplete Killian's operation was carried out on the left side. The size and disposition of the sinuses before the operation were shown by a skiagram. The case illustrated the superiority of Killian's complete operation to any other in extensive suppurative disease of the upper sinuses. There was an almost entire absence of deformity over the right sinus but there was slight deformity over the left, where an incomplete, but otherwise successful, operation had been performed.

Mr. **T. H. OPENSHAW** exhibited an appliance for obtaining Extension of the Spine in the Treatment of Scoliosis and Caries. This consisted of a bed made of plaster-of-Paris, which was accurately moulded to the whole dorsal surface of the patient, from the head to the heels. It fitted with the utmost accuracy, with the result that the patient could lie on the back during the whole night or for 24 hours without the slightest discomfort. It was specially fitted with an arrangement of pulleys, weights, and a Glisson's sling in order to extend the spine. Counter-extension was obtained by means of a leather pelvic girdle which was attached by straps to the iron framework of the plaster bed. This pelvic girdle was accurately moulded to the iliac crests and pelvis, thus obviating pressure sores. There was also attached to the middle line of the plaster bed at a point corresponding with the centre

THE ACCURACY OF OPSONIC ESTIMATIONS.

BY L. NOON, B.C. CANTAB., F.R.C.S. ENG.,
JOHN LUCAS WALKER STUDENT IN THE UNIVERSITY OF CAMBRIDGE;
AND
ALEXANDER FLEMING, L.R.C.P. LOND., M.R.C.S. ENG.,
ASSISTANT IN THE INOCULATION DEPARTMENT AT ST. MARY'S HOSPITAL.

(From the Inoculation Department, St. Mary's Hospital.)

Dr. A. Reyn and Dr. R. Kjer-Petersen, in THE LANCET of March 28th, publish figures on which they question whether the tuberculo-opsonic index of tuberculous patients really does present any specific variation from the normal. This is a blow aimed at the very base of all opsonic work, and we feel that an answer to the attack is not out of place.

Some sources of error to which the technique is liable are discussed by one of us in a paper which is due to appear in the *Practitioner* for May of this year; so that we can here confine ourselves to the criticism of Dr. Kjer-Petersen's figures, against which we produce some figures obtained at St. Mary's Hospital in the routine work of the Inoculation Department.

Our argument is arranged under four heads, which deal respectively with (1) Dr. Kjer-Petersen's position; (2) our reasons for regarding the variations of normal sera as small; (3) our reasons for regarding the variations of tuberculous sera as large; and (4) some general criticisms of Dr. Kjer-Petersen's methods.

1. *Dr. Kjer-Petersen's position.*—Dr. Kjer-Petersen presents us with the mean error or *standard deviation* of his three series of observations and proceeds to show that each series approximates to the distribution known as the "normal curve of error." This implies three propositions. (*a*) The calculated *standard deviation* of each series is a measure of the variation of the observations. (*b*) Nearly 70 per cent. of observations will fall within this limit, and deviations larger than four times the *standard deviation* are only to be expected six times in 100,000 trials.[1] (*c*) When we are presented with the *standard deviation* of a series of observations, we are face to face with a number which represents deviations due to many causes. If, by any means, we can find out the *standard deviation* due to one of these causes acting alone, we can eliminate this (by squaring both numbers, subtracting, and taking the square root of the remainder), and so obtain the *standard deviation* due to the remaining causes.

From what precedes we see that Dr. Kjer-Petersen's figures are open to analysis, if we can obtain the necessary data from which to work. Before we undertake such a task we wish to draw a distinction between certain terms which we shall use. When we speak of the *standard deviation* presented by a series of observations, it is to be understood that the individual observed deviations may be due to *errors* introduced by imperfect technique, or, on the other hand, to actual *variations* in the biological quantity measured. Therefore we speak of a *standard deviation* as compounded of a *mean error* of observation and a *mean variation* of the quantity measured.

Having made these definitions we may now approach Dr. Kjer-Petersen's figures and make use of the statistical method in which he trusts. We shall see what conclusions may be drawn from these figures.

Dr. Kjer-Petersen finds a *standard deviation* (from unity) in his observations on normal sera of 0·19, as opposed to 0·25 and 0·29 in two series of tuberculous cases. *The standard deviation* 0·19, for normals, represents *variations* in the normal sera used and *errors* in the technique of opsonic estimation. One or other of these factors must be considerable. If the variations of normal sera have been more important than the errors of technique, then the difference between 0·19 and 0·25, or 0·29 (the difference, that is, between normal and tuberculous serum), is not of great value, and Dr. Kjer-Petersen's criticism is justified. If, on the other hand, the *errors* have been more important than the *variations*, then no definite conclusions can be drawn from his figures.

We propose to show that the variations of normal sera are small in comparison with the figures given above. Consequently Dr. Kjer-Petersen's work lacks accuracy. Hence we may set aside his conclusions in favour of others which are supported by better figures.

2. *The variations of normal sera are small.*—The records of routine work in the Inoculation Department of St. Mary's Hospital have supplied us with 763 pairs of observations on normal sera. The samples of serum have been obtained from 60 presumably normal individuals, who from time to time offered themselves for this purpose. The difference between the counts for the two normals we have expressed as a percentage of the mean of the two counts. Bearing in mind Mr. M. Greenwood's letter, in THE LANCET of April 11th, we are careful to premise that we have attempted, not a complete mathematical treatment of these data, but an approximation, which is still near enough to justify our rejection of Dr. Kjer-Petersen's results. Our figures are distributed very nearly acccording to the normal curve of error and give a standard deviation of 10 per cent. Table I. gives the observed distribution, compared with the theoretical, which is enclosed in brackets.

TABLE I.

Within 5 per cent.	326 = 427	per mille	(383).
„ 10 „	558 = 731	„	(683).
„ 20 „	722 = 945	„	(954).
„ 30 „	754 = 988	„	(997)
„ 40 „	762 = 999	„	(999·94).

What does this *standard deviation* of 10 per cent. mean? It is not the *standard deviation* of single observations from a hypothetical mean normal; it represents two such deviations, because it measures the difference between two observations, both of which may vary. Then the value 10 per cent. is compounded of two equal *standard deviations* from the mean normal. Observations of the indices of normal sera are consequently subject to a *standard deviation* of $\frac{10}{\sqrt{2}}$, or 7 per cent. Estimations of unity, depending on the mean of two such observations, are subject to a *mean error* of $\frac{7}{\sqrt{2}}$, or 5 per cent.

Now this *standard deviation* of 7 per cent. is compounded of the *mean variation* of the opsonic indices of normal sera, and the *mean error* of observation at St. Mary's Hospital. Either of these unknown quantities must therefore be less than 7 per cent. That such a deviation is relatively small may be seen by correcting Dr. Kjer-Petersen's figures in the light of our own. Suppose for example we assume a *mean variation* for normals of 7 per cent. (the largest our figures admit); this corresponds to 0·07 of unity. Eliminating this factor from Dr. Kjer-Petersen's *standard deviation* of 0·19, we are left with a *mean error*, for Dr. Kjer-Petersen's observations, of between 0·17 and 0·18, which we must attribute wholly to imperfections in his technique.

Having said this, we must examine the method by which our figures have been obtained. Most observers either knew, or were liable to know, when they were counting their "normals." This introduces the question of bias. Then, 100 cells were counted in most cases, but a second lot of 100 has been counted, at the observer's discretion, if the normals were found to disagree widely, or if the phagocytosis in any film appeared to be irregular. This introduces the question of reduction of error by taking larger samples. That neither this practice of revision, nor personal bias, has tended to reduce divergencies to any serious degree is the opinion of most practised observers. This opinion is supported by the following facts. (*a*) The close agreement of the distribution of our figures with the law of error. We lay stress on this, because Dr. Kjer-Petersen himself insists that "the influence of any predominant cause" will prevent a correspondence to the law of error. (*b*) During the last two months one of our fellow-workers, to avoid entirely the question of bias, has had his slides re-numbered and mixed up, being thus quite in the dark as to which of his slides were controls. During this time he has made 22 pairs of observations on normal sera, counting only 100 cells of each slide. The *standard* line and the dulness showed that the organ was enlarged on the right side also. On palpation the heart beats were found to take place in pairs, a forcible beat being followed prematurely by another beat of less intensity. Each pair of beats was followed by a pause. As a rule, the feebler beats did not reach the wrist, pulsations at the heart and the radial artery being as 120 to 60. There was a presystolic thrill every few beats at the apex and a systolic thrill was present over the base which was most marked over the pulmonary area. The heaving action of the right ventricle could be felt to the right of the sternum. At the apex a presystolic murmur was often audible. A systolic murmur was to be heard all over the præcordium during the forcible cardiac beat, only this murmur was loudest over the pulmonary area. Since first seen the patient had been kept in bed for five weeks and digitalis was administered during part of the time. For the last seven weeks she had been taking 5 minims of Fowler's solution three times a day but her condition remained unchanged.—The case was discussed by the PRESIDENT and Dr. WILFRED HARRIS.—Dr. SYMES-THOMPSON replied.

---

[1] It must be remarked, however, that the frailty of human nature may introduce into any collection of measurements occasional large errors which are neglected by the "law of error" in its simplest form. If such errors are rare, statisticians generally reject them from their calculations and content themselves with recording their occurrence. For this purpose they use Chauvenet's criterion, which they apply in order to define a *limiting deviation*. An observation which falls outside this limit is not included in the determination of the constants of a curve.

Mr. T. H. KELLOCK exhibited a case of Paraffin Injection for Depressed Nose four years after operation in a patient, 23 years of age. The length of time that had elapsed since the operation made him hopeful that the successful result would be permanent.

HARVEIAN SOCIETY OF LONDON.

Treatment of Incompletely Descended Testis.—Clinical Cases.

A MEETING of this society was held on April 9th, Mr. D'ARCY POWER, the President, being in the chair.

Mr. LOUIS B. RAWLING read a paper on the Surgical Treatment of the Incompletely Descended Testis, based on an investigation of 120 cases admitted into St. Bartholomew's Hospital during the past five years. The conditions prior to, and at, operation were alluded to and it was shown that the almost constant presence of a peritoneal process added to the necessity of operative treatment. In dealing with the question of the treatment of the affected testis those cases were first discussed in which one organ was normally placed whilst the other was incompletely descended. Scrotal placement was attempted in 40 cases, in 29 of which the ultimate result was observed. In 25 of these the late result was unfavourable, the testis either retreating to the pubo-scrotal, pubic, or inguinal regions, and becoming small and atrophic. In four cases only was the result at all favourable. The remaining cases could not be traced, though in three the early result showed that only failure was to be expected. For these and other reasons it was obvious that scrotal placement except in the most favourable cases was doomed to failure from the very beginning. The three alternatives, of allowing the testis to remain in the inguinal region, replacing it in the abdomen, or removing it altogether, were then considered. All evidence pointed to the fact that the inguinal testis was a source of great discomfort to the patient and that it was more than usually liable to infection, torsion, and malignant disease, whilst the uselessness of the replaced testis from a spermatogenetic point of view was generally acknowledged. In 50 cases the testis was removed, the patients being of all ages, and it was apparent that the removal of the one organ in no way interfered with the mental or physical development of the patient and the procreative powers were in no wise impaired. The normally placed testis fulfilled all the desired functions, internal and external. Granting, therefore, that due time was allowed for the further descent of the organ and that exposure showed that scrotal placement was out of the question, it was advisable that the affected organ should be removed and the inguinal canal sewn up. Attempts to place the testis in the scrotum offered the best chance of success when the operation was carried out after seven years of age and well before puberty. With regard to double failure in descent, it appeared necessary that every effort should be made to place the testes in the scrotal region, for the examination of testicles removed showed that the spermatogenetic functions were more active when the organ was in that position than when abdominally replaced. All evidence showed that the abdominally replaced testes were functionless from a procreative point of view and double abdominal replacement was therefore most inadvisable. In case of failure in scrotal placement it was even preferable that the testes should be allowed to remain in the canal rather than that they should be abdominally replaced.—The paper was discussed by the PRESIDENT, Mr. W. M. ECCLES, Mr. E. M. CORNER, Mr. E. LAMING EVANS, Mr. LAWRENCE JONES, Mr. IVOR BACK, Mr. CAMPBELL WILLIAMS, Mr. T. CRISP ENGLISH, Mr. KENNETH A. LEES, and Dr. T. CLAYE SHAW.—Mr. RAWLING replied.

Dr. KENNETH LEES showed a case of Ruptured Aortic Valve.

Dr. D. W. CARMALT-JONES showed a case of Ataxy of acute onset in association with Tabes Dorsalis.

Dr. W. H. WILLCOX exhibited a case of Arterio-Sclerosis with Retinal Changes following Parenchymatous Nephritis in a boy aged nine years.

Mr. CRISP ENGLISH showed a case of Scrotal Tumour.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Unusual Cause of Dysenteric Diarrhœa in the Tropics.

A MEETING of this society was held on April 15th, Dr. F. M. SANDWITH being in the chair.

Dr. W. T. PROUT communicated some notes on an Unusual Cause of Dysenteric Diarrhœa in the Tropics. The small epidemic to which the notes referred occurred when he was chief medical officer of the Gambia. There was a company of the West India Regiment stationed there and as there was no army medical officer available he was for a considerable period the medical officer in charge and it was among the men of that company that the outbreak occurred. It took place in the early part of the rainy season—that is to say, the weather was still fine and clear but there were occasional heavy showers of rain. The men lived in large barracks, which formed two sides of a large square, and though old these barracks were clean and on the whole in good sanitary condition. It was important to note that the water-supply of the troops was derived solely from rain-water which was stored in large iron tanks. Towards the end of the dry season, as the tanks became empty, they had been thoroughly cleaned and whitewashed inside, while the inlet pipes had been disconnected until the first shower had washed the collecting area, which was the barrack roofs. At the time of the outbreak the tanks were pretty well filled. One day a man presented himself to him (Dr. Prout) at the hospital complaining of griping pains and diarrhœa with a certain amount of blood in the motions. There were very little constitutional disturbance, very little tenesmus, and none of the serious signs of an attack of acute dysentery. He (Dr. Prout) very naturally paid little attention to it until one after another of the soldiers came to him suffering from the same symptoms. At the beginning of the rains, when the water-supply was very liable to contamination, diarrhœa was by no means uncommon, but at that time curiously there were no cases of dysenteric diarrhœa among the civil population, so that it was clear that the cause was one confined to the troops. He had thought at first that some of the men had been drinking water in the town, but he was able practically to exclude that. The drinking water of the native population was derived from shallow surface wells, from four to eight feet deep, and as Bathurst was simply a sand bank the water was often brackish, and the men did not like it after being accustomed to the pure rain water. He need hardly say that the water in those wells was very much polluted as they often found a cess-pit a few feet away. He had, then, to seek the cause in the barracks, and he must confess that after the precautions which had been taken with reference to the tanks he did not at first examine the water very carefully. He had a bucketful run off and it appeared clear, sparkling, and had no bad taste or odour. An inquiry into the food-supply and a careful inspection showed nothing wrong, the men absolutely denied having eaten or drunk anything outside which could have disagreed with them, and the barrack-rooms and latrine arrangements were in perfect sanitary condition, so by a process of exclusion he was driven back to the water. He had one of the manholes taken off one of the tanks, a bucket sunk to the bottom, tilted over, and dragged along; he then found that there appeared to be some sediment. With some reluctance, for one does not like to waste good drinking water in Bathurst, he gave instructions that the water should be run off and he found at the bottom a deposit three weeks to subside, though not severe. On June 1st venesection was performed, 24 ounces of blood being drawn off. Examination of the blood gave the following result: specific gravity, 1081; red cells, 9,140,000; hæmoglobin, 160; white cells, 91,000, consisting of polymorphs 93·2, eosinophiles 1·2, large lymphocytes 2·6, small lymphocytes 2·4, and myelocytes 0·8 per cent. There were two nucleated red cells to each 500 whites. The red cells varied a little in size and shape. The blood clotted in from six to ten minutes and the viscosity coefficient was 51·2. The volume of corpuscles was 90 per cent. As a result of the bleeding the patient felt very much better and the blood examination showed next day: red cells, 8,050,000; hæmoglobin, 125; white cells, 50,000; and polymorphs, 94 per cent.

The number of red cells and the amount of hæmoglobin kept about the same during the next five weeks. The white cells ranged from 50,000 to 72,500. The patient was then bled again to the extent of 34 ounces. Examination of the blood showed that the specific gravity was down to 1073·5 and the volume of corpuscles to 85 per cent. A week later the number of red cells was reduced to 7,650,000 and white cells to 68,000. 1480 cubic centimetres of urine were passed in the 24 hours; it was of specific gravity 1012, acid, and contained one-half albumin (Esbach), granular and hyaline casts; P_2O_5 0·07 per cent., equivalent to 1·035 grammes; and chlorides 0·45 per cent., or 6·6 grammes. The patient felt much better and was discharged. During his stay in hospital the temperature was generally subnormal, ranging between 97° and 98° F., occasionally reaching 99°. The pulse-rate varied between 76 and 108, the most constant rate being between 80 and 90. The daily output of urine averaged 57 ounces, with a minimum of 21 and a maximum of 106 ounces; its specific gravity was 1008–1015. A trace of albumin was still present when he left the hospital. He gained about a pound in weight. Observations were made subsequently on the blood and urine but showed no special changes from the condition on discharge, except for an increase in the albuminuria. Death resulted from cerebral hæmorrhage on Feb. 4th, 1907.

Necropsy.—Post mortem the body was very cyanosed. The heart's blood was sterile. There was large hæmorrhage into the left cerebral hemisphere. The veins in the neck and chest were much distended with very dark bluish-black fluid blood (two days after death). The lungs were engorged. There were pleural adhesions at the left base and over the right upper lobe. The heart was 16 ounces in weight; the right side was distended with blood and clots; the walls were rather friable. There was slight atheroma of the aorta, aortic and mitral valves, and coronary arteries. As regards the abdomen, there were firm adhesions around the spleen, between it and surrounding organs. The liver weighed 72 ounces and was of a natural colour and structure. The spleen weighed 18 ounces, was firmly adherent to the surrounding structures, and contained one very large and one small, soft, yellow, diffluent, breaking down infarct. The rest of the spleen was divided into rounded lobules of soft splenic tissue, chocolate-brown in colour, separated by fibrous tissue. The suprarenals were normal. The right kidney weighed two ounces and was granular; the left kidney weighed eight ounces and was slightly granular. The left testis was small, fibrous, and puckered. Microscopical examination of the various organs and the bone marrow afforded no indication of the etiology of the condition. Most of the post-mortem appearances could be explained as the result of local thrombosis of the extremely viscid blood.

Remarks.—Although any condition of cyanosis induces polycythæmia it does not follow that the increase in the number of red cells is due to the cyanosis in cases of the above type. More probably there is an actual increase in the production of red cells and the cyanosis is consequent on the increasing viscosity of blood and difficulty in its efficient aeration. The considerable increase in the number of white cells, especially in the polymorphs, suggests that we have to deal with an inflammatory affection of the blood-forming organs, possibly the result of some toxin. In many instances the number of white cells is little increased. So far microscopical examination of the various organs has yielded no positive information. Venesection in this patient certainly relieved the symptoms considerably. The omission of milk from the diet and large doses of sodium citrate did not appear to produce any beneficial effect.

I am indebted to Dr. H. Beckett-Overy and to Mr. Ernest Shaw for the careful pathological observations above recorded.

Upper Brook-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF APPENDICULAR ABSCESS CONTAINING A PIN.

By J. Marcus Hayes, L.R.C.P. & S. Irel.,
LATE HOUSE SURGEON, STROUD HOSPITAL; LATE HOUSE PHYSICIAN AND HOUSE SURGEON, ST. VINCENT'S HOSPITAL, DUBLIN.

In connexion with the subject of appendicitis the following case may be of some interest.

The patient, a female, aged 28 years, unmarried, was admitted to Stroud Hospital on Sept. 11th last with the following history. She had "always been delicate," and about ten years ago she first complained of great weakness across the lumbar region. She started work as a tailoress about five years afterwards but the pain in her back becoming much worse she had to give up her employment three years ago. At this time (i.e., three years ago) she first complained of pain in the right side, localised in the right iliac region and occasionally shooting down the outside of the right thigh. The bowels were not regular and she had two or three attacks of severe abdominal pain. About this time she also suffered a good deal from sickness of the stomach which occasionally brought on vomiting but she did not connect this sickness and vomiting with the pain. She said they occurred at different times; the sickness and vomiting came on, as a rule, after breakfast. She was not able to give any more definite information except that for the past three years she had had a persistent slight pain or feeling of uneasiness in the right side, the pain being sometimes very severe and of a "screwing and burning" character, but was much relieved when she lay flat on her back. She had been seen from time to time by different medical men and a good deal of her trouble was attributed to neurosis. She had been in bed for two weeks with one of these attacks of pain just before her admission to hospital, and on admission she looked sallow and distinctly ill. The temperature was 97° F., the pulse was 80, and the tongue was fairly clean. She localised the site of pain about one and a half inches inside the right anterior superior spine. There was no swelling or area of dulness but a good deal of tenderness on pressure. The bowels acted that evening without an aperient. During the next two days the temperature was subnormal and the pulse was about 80; she did not complain of pain but said she felt weak and giddy, and there was still much tenderness on pressure.

On Sept. 14th, under an anæsthetic, a hard, well-defined mass was felt in the appendix region. The usual incision for appendicectomy was made and was continued to a length of about three inches. There was considerable thickening of the peritoneum, and this having been divided the cæcum immediately presented. It appeared to be normal and was not bound down in any way by adhesions. On following down its anterior longitudinal muscular band the root of the appendix was found; it looked congested and dilated to about the size of an average terminal thumb phalanx. In endeavouring to isolate the appendix it was found that what should have been the body and tip of the organ was in reality a hard mass of about the size of a golf ball, imbedded in the substance of the iliacus muscle, but continuous with the base of the appendix. The cæcum and other coils of intestine having been carefully packed off, an attempt was made to isolate the mass, but in so doing it burst and about one and a half drachms of most offensive pus and some inspissated material (which contained evident remains of the wall of the appendix) were discharged. This was removed and then the tip of the finger could be worked around a pretty large cavity containing a quantity of this inspissated débris, which was removed piecemeal. On examining one of the small concretions so removed it was found to be formed around the head of an ordinary pin one and a half inches long. The cavity was cleared out as well as possible and a counter-opening was made through the loin. Through the latter, and also through the wound in front, there was a copious discharge of most offensive pus for three weeks. As the evening temperature was remaining up, being regularly 100° or 101°, the wound in the loin was explored on Oct. 8th, and as the pus was burrowing upwards obtained in 2. Altogether 17 were free, 5 had recurrence, 7 had died from the disease and 2 from the operation, and there was no report in 4. Those free had been operated on in years and months respectively, 3·4, 3·0, 2·11, 2·11, 2·10, 2·5, 2·2, 1·10, 1·9, 1·7, 1·3, 1·2, 1·1, 1·0, 0·5, 0·4, 0·4 = 17. Mr. Paul strongly advocated a definitely planned attack on the glands in all suitable cases of cancer. He previously thought that the importance of this had been fully recognised for several years. But it was one thing to accept a general principle and another to adopt a definite plan of attack, and since he had carried out thoroughly the details of Butlin's operation on the neck his results in tongue cases had been infinitely better than they ever were before.

Dr. H. DRINKWATER read a paper on Brachydactyly—a Study in Heredity, giving an account of a brachydactylous family. The chief defect in these people consisted of an abortive condition of the middle phalanx in all the digits both of hands and feet. Sometimes in the middle and ring fingers this middle phalanx was reduced to a small cubical bone, but in most instances it had become ankylosed to the ungual phalanx. In no instance was it seen as a separate bone in the first or fourth finger or toe. The first phalanx of the thumb was greatly shortened and in young children showed no sign of an epiphysis. In this respect it had undergone precisely similar changes to the middle phalanx of the fingers. The epiphysis of the so-called metacarpal bone of the thumb was at its base, whereas that of the other metacarpals was at the distal end. This showed that the metacarpal bone of the thumb was in reality the first phalanx and that the first phalanx was homologous with the second phalanx of any other digit. The same held good for the big toes. The metacarpals were all short and undulated at the distal ends. There were 25 people living belonging to one family who showed these defects. The stature and the finger measurements of the "abnormals" of these families were always less than the "normals." The hands and feet were always symmetrically affected. They were prolific, with from eight to 17 children in a family; one woman had had 99 descendants (three generations). The fecundity of the women exceeded that of the men. There was not a single abnormal individual over 23 years of age who had remained single, whilst among the normal relatives more than a dozen had remained single. The defect had been traced through seven generations comprising 174 individuals. Among the children of abnormal parents the defect was found in over 50 per cent., thus agreeing with Mendel's law of inheritance. The children of normals were in every instance normal. The deformity prevented the abnormals from learning trades requiring manual dexterity. They were all English.—Dr. T. R. BRADSHAW said that the great point of interest in the paper from the view of the physician was the possibility of the inheritance of disease taking place on Mendelian lines, so that they could in many cases assure their patients that unaffected individuals need have no fear of transmitting a family disease to their posterity. Unfortunately, there were many diseases which were clearly transmitted by unaffected people, as was shown by Dr. A. M. Gossage in the current number of the *Quarterly Journal of Medicine*.—Dr. R. J. M. BUCHANAN thought that the study of heredity in disease was important in that it might throw light on the etiology of diseases about which they still remained more or less ignorant. He had found a tendency to hereditary transmission in pernicious anæmia and quoted an instance which he had met with of a mother and two sons having died from this disease; there seemed to be an hereditary tendency in the splenic anæmia of adults.—Dr. HUBERT ARMSTRONG recalled the case of a family of which some years ago he had been able to show before the institution several members in three generations. The deformity in these was microdactyly and their hereditary history was very similar to that of Dr. Drinkwater's series and they were also symmetrical.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Duodenal Ulcer.

A MEETING of this section was held on April 3rd, Dr. JOHN M. FINNY being in the chair.

Mr. ARTHUR B. MITCHELL (Belfast) read a communication on the Diagnosis and Treatment of Duodenal Ulcer, based on a series of 19 cases which he had operated on during the previous year. He said that this was a more serious condition than gastric ulcer, being much more liable to become perforated and to lead to fatal hæmorrhage and being also less amenable to treatment by medical means. As prominent symptoms he specified (1) "hunger-pain"; (2) discomfort after food; (3) local tenderness above, and to the right of, the umbilicus; (4) hæmatemesis and melæna; and (5) early dilatation of the stomach. He thought that (at all events in chronic cases) the only reliable and efficient method of treatment was by a surgical operation.

Dr. JAMES LITTLE said that he agreed with Mr. Mitchell's view that duodenal ulcer was much more frequent in men than in women; he had also found it much more frequent among private patients than among hospital patients.

Dr. THOMAS G. MOORHEAD said that hyperchlorhydria had been a typical symptom in the cases of duodenal ulcer which he had seen.

Mr. FRANK K. CAHILL said he had been able to diagnose duodenal ulcer through giving foods of different degrees of digestibility, such as beef and pork, and watching the time relation of the onset of pain.

Dr. JOSEPH F. O'CARROLL said that they might regard gastric cases as being either muco-gastric and associated with a diminution of acid secretion or associated with an excess of acid secretion, or a necrotic or ulcerated condition. These three divisions would form a serviceable basis for diagnosis. They might assume that excess of acid was in many cases associated with ulceration in the stomach or duodenum. He hoped that they would in future be able to diagnose the condition at a stage that would prevent cases having to go to operation. Tests for acid were not always absolutely reliable, as in some cases the acidity of the stomach overstayed its emptying and set up an ache which might be relieved by food. He agreed, of course, that if they could be sure of the diagnosis there should be operation on the spot.

Mr. MITCHELL, in reply, said that he agreed with Dr. O'Carroll's remarks and had himself declined to operate in certain cases. While it was valuable to have an outstanding symptom that would give a direction to their thought it would be a mistake to regard a single symptom as infallible. He had not, however, found a case of duodenal ulcer in which there was not "hunger-pain."

GLASGOW SOUTHERN MEDICAL SOCIETY.—At a meeting of this society held recently Dr. James Mackenzie of Burnley delivered his presidential address, the subject being Some Platitudes and the X Disease. He first thanked the society for the honour which it had bestowed on him in asking him to be its honorary president—an honour which he had appreciated all the more as it was the first recognition which he had received from his own country of Scotland. All his life he had been a general practitioner he was proud to say and all his work had been done in that capacity, and it was to the general practitioner he felt that they must look for the greatest advances in medicine in the future. He was going to speak to the society on some of the "ignored trifles," the things taken for granted, the platitudes of medicine. The first platitude was the necessity for careful observation of the patient and the understanding of what they saw. In his own case the first subject in which he had particularly directed his attention was that of pain. He had begun by making notes as full as possible as to the position and character of pain complained of by patients. He found that in a large number of cases of visceral disease (such as gall-stones, intestinal and renal colic, &c.) hyperæsthesia of the superficial tissues was present—never in definite areas as Head averred—but with an indefinite changing border which was characteristic. The muscles as well as the skin showed this hyperæsthesia and the abdominal muscles (unlike other long muscles) could contract in segments over the painful lesion. Two instances were cited where a hyperæsthetic area at a distance might be either a help or a stumbling block in the diagnosis according to the experience and knowledge of the medical man. In the first case (one of gall-stones) the hyperæsthesia was present in the shoulder and arm, and in the second (one of renal calculus) the hyperæsthesia was in the skin of the scrotum. It was a most striking fact, he said, that of all the serous membranes the tunica vaginalis was the only sensitive one. The second platitude was to observe what became of their cases. There was the greatest need for this observation on the part of the general practitioner since he was the only man who could finally answer such questions as Was this cardiac murmur pallor and languor for some weeks, while the duration from onset to death varied from three or four months in the more prolonged to under two weeks in the rapidly fatal cases. The average duration was five weeks. The clinical features were marked by progressive anæmia, associated with a tendency to hæmorrhages in the form of purpura, retinal or conjunctival hæmorrhages, bleeding from the gums, epistaxis, or more rarely hæmaturia or hæmatemesis. The cases also presented, usually but not invariably, slight general enlargement of the lymphatic glands, more obvious enlargement of the spleen and liver, and in a few instances the kidneys were palpable. Diarrhœa and vomiting were not uncommon at the onset and during the course of the disease. The temperature was irregularly raised. The urine in several cases contained traces of albumin. Blood examination showed an increasing diminution in the number of red corpuscles to yield a figure between 1,000,000 and 2,000,000 per cubic millimetre or lower, and the colour index varied between 0·5 and 1·5. The highest leucocyte count obtained was 1,000,000 per cubic millimetre; three other cases yielded counts of 321,000, 196,000, and 126,000 leucocytes per cubic millimetre; and in six cases the number varied from 81,000 to as low a figure as 3500 per cubic millimetre. The frequency with which the leucocytes showed a considerable fall in numbers, preceding death, was pointed out, and was attributed to the probable influence of a terminal septicæmia. Differential counts of the leucocytes yielded in all cases a marked absolute or relative lymphocytosis, the percentage of lymphocytes varying from 66 in the earlier to 99 in the later course of the disease. The large lymphocyte tended to predominate in the acute, and the small lymphocyte in the more prolonged cases, but this feature was subject to variation according to the stage of the disease. On post-mortem examination there was found usually slight enlargement of the superficial and deep lymphatic glands. The pericardium and pleuræ were scattered with punctate hæmorrhages. The spleen and liver were enlarged. The kidneys in the majority of cases were much increased in size and displayed extensive hæmorrhagic and pale mottling. The intestines showed but little change beyond a few hæmorrhages and swelling of Peyer's patches. The bones showed no alteration and the marrow, which varied in colour from pale to dark red, did not appear increased in amount. In four cases short streptococci were obtained in pure culture from the heart's blood, spleen, and other organs, and from the marrow in two cases. The streptococci conformed in subculture and fermentation tests with the behaviour of streptococcus salivarius. The microscopical changes characteristic of the disease were illustrated by means of coloured drawings, demonstrating lymphocytic invasions with occasional hæmorrhages into the connective tissues of the heart muscle, liver, spleen, lymphatic glands, and kidney. The extensive changes, both macroscopic and microscopic, found in the kidneys were emphasised as a common and striking feature. The appearances of the blood and marrow were also shown by drawings of film preparations, displaying large numbers of lymphocytes. In discussing the pathogeny of lymphocythæmia, it was pointed out that the weight of evidence of most recent work was strongly in favour of the marrow being the primary seat of disease, while the changes found in the blood and various organs were probably secondary. Some support had been given to the view that the disease was of microbic origin and that the lymphatic glands were primarily involved as the result of infection. Though the bacteriological investigation of previously recorded cases and of those above described showed the presence of a streptococcal infection, yet there was strong probability of such infection being merely terminal or intercurrent rather than primary. Reference was also made to the suggestion that the disease originated in the thymus, but little evidence could be brought in support.—The PRESIDENT related the details of a case pointing to an infective origin but admitted the possibility of explaining what was taken to be the septic focus as an accompaniment of the disease rather than its starting point. —Dr. F. J. POYNTON described a case similar to that narrated by the President. He favoured the idea that the infective theory of the origin of the disease was the correct one and urged the importance of experimenting on animals to elucidate the point.—Dr. FORBES was not prepared to admit that the cases arose primarily in the marrow and Dr. LANGMEAD said that clinically the cases closely resembled acute septicæmia.

Dr. FRANCIS H. HAWKINS recorded a case of Multiple Rheumatic Nodules in an Adult. The patient, a woman, aged 35 years, had had rheumatic fever at the age of 17 years followed by chorea. A second attack of rheumatic fever occurred three years later and was accompanied by the formation of nodules on the head and spine. Following a more recent attack nodules were observed on the spinous processes of the dorsal vertebræ, both scapulæ, both ulnæ, the skull, and the left index finger. A year later the only nodules which could be detected were on the clavicles.

Dr. LEONARD G. GUTHRIE and Mr. M. STEPHEN MAYOU recorded a case of Right Hemiplegia with Atrophy of the Left Optic Nerve. Dr. Guthrie said that the patient, a boy, aged seven years, was in July, 1906, run over by a cab and sustained fracture of several ribs on the left side. Three days later he developed pneumothorax on the left side. Six days after the accident he became aphasic, hemiplegic on the right side, and blind in the left eye. Speech had now returned and he had partially recovered from the hemiplegia. The left optic disc was completely atrophied, the ophthalmoscopic appearances being those of complete occlusion of the arteria centralis retinæ. Intelligence and physical health were good. No trace of the left common carotid artery nor of its terminal facial and superficial branches could be detected. The simplest explanation was that those vessels and the left middle, central, and ophthalmic arteries became occluded by thrombi formed in the heart and escaping into the circulation at the time when pneumothorax occurred. The boy's healthy mental and physical condition, however, was against such extensive occlusion of vessels. Possibly the left cervical arteries were abnormal and occlusion had only taken place in the arteria centralis retinæ and branches supplying the neighbourhood of the left internal capsule.

Mr. CHARTERS J. SYMONDS showed a case three years and nine months after complete Excision of the Larynx illustrating an improved method of speaking. The patient, aged 52 years, was admitted to Guy's Hospital in July, 1904, with extensive malignant disease of the larynx affecting primarily the left side. The disease had penetrated the left ala and involved the muscles. Complete extirpation was carried out in the usual way, together with removal of the thyrohyoid and sternohyoid muscles on the left side. The fascia with lymphatics and the left thyroid lobe together with all surrounding fascia were also removed. The trachea was attached to the skin above the sternum and the pharynx was closed with three rows of catgut sutures. Primary union was obtained. The patient was shown in order to exhibit his phonetic power, especially with the aid of the device suggested by Gluck, which by inserting a rubber tube into the cannula carries a current of air to the lips. By this means the patient could be heard at some distance and was able to carry on his duties. There was no difficulty in swallowing.

Mr. SYMONDS then showed a patient, aged 65 years, in contrast to the first case. On Oct. 17th, 1906, the left cord was removed for a strictly localised malignant growth. The excellent voice retained represented the average phonetic result when the arytenoid was not interfered with and the opposite cord was not injured in the operation.

Mr. W. SAMPSON HANDLEY showed two cases illustrating the results of Lymphangioplasty for the Brawny Arm of Breast Cancer. This procedure was described in THE LANCET of March 14th, p. 783, and consists of the introduction into the subcutaneous tissue of the swollen arm of a number of buried silk threads running longitudinally up to the axilla.—Mr. CECIL H. LEAF described the successful results which he had obtained by venesection.—Dr. F. PARKES WEBER suggested that Mr. Handley's method might be useful in elephantiasis.—Dr. J. P. ZUM BUSCH narrated how he had secured relief by the use of silver wire.—Mr. HANDLEY agreed that his method by silk threads was applicable to other conditions of lymphatic œdema.

Dr. HAWKINS showed a case of Ascites treated by paracentesis performed 25 times in 15 months. He said that the patient, a man, aged 43 years, began to suffer from swelling of the abdomen and feet, with loss of flesh, in August, 1899. He had never been a heavy drinker and had not suffered from venereal disease. When the patient came under observation in September, 1899, there were œdema of the lower limbs and slight œdema of the chest wall and sacral region. The abdomen contained a large quantity of free fluid. The heart sounds were normal. The urine on some occasions contained blood and albumin. The abdomen was tapped on 25 occasions during a period of 15 months, the maximum amount of fluid withdrawn being 36 pints. Since December, 1900, the patient had had good health and had followed his occupation as a gardener.

showed cases of Acute Anterior Poliomyelitis in an adult, Hæmatomyelia, Ataxic Paraplegia, Tricuspid Disease, and Complete Transposition of the Viscera.—Mr. S. Snell showed the following: 1. Two cases of Steel in the Eye removed by the electro-magnet. Both were in the vitreous. In one the chamber was filled with blood, but, nevertheless, eight weeks after the accident removal of the foreign body through the sclerotic was followed by excellent vision. The other was adherent by one extremity to the posterior capsule, the other end being free and moving on the approach of the magnet. It was immediately removed through the sclerotic incision. 2. Three cases of Excision of the Lacrymal Sac for Chronic Dacryocystitis. 3. Six cases of Hypopyon Ulcer which had been treated by anti-pneumococcic serum. 4. Streptococcal Inflammation of the Eyelids (treated with serum) and a rare Tumour of the Lid. 5. Two cases of Symblepharon treated by grafts; one, Thiersch, the other, conjunctival from another case. 6. A case of Ectropion treated by a non-pediculated flap 20 years ago, the result remaining excellent.—Mr. R. J. Pye-Smith showed a man, 30 years of age, with Dislocation of the Cervical Spine. He had been caught in a revolving shaft. Some thick steel tools in his pocket were much bent. His head was now permanently flexed and projected forwards. He could move the head at the occipito-atlantal and atlanto-axial joints. There was no paralysis. The dislocation was thought to be about the third or fourth cervical.—Mr. Graham S. Simpson showed a boy, aged 16 years, suffering from Spondylitis Deformans. The disease started four years ago in the right hip. Since then the spine had become increasingly stiff and there was now no movement possible from the seventh cervical to the coccyx. The disease resembled osteo-arthritis in its exacerbations of pain at the onset of wet weather.

Pathological Society of Manchester.—A meeting of this society was held on April 8th, Dr. J. J. Cox, the President, being in the chair.—Dr. D. Orr and Dr. R. G. Rows showed lantern slides illustrative of the Toxic Lesions of the Spinal Cord found in cases of Abdominal Cancer. The characteristic change consisted of atrophy of the myelin sheaths in the central portions of the cord and was most marked in the cervical region.—Dr. A. Corsar Sturrock described a case of Hæmangeio-endothelioma of the Liver. It occurred in a woman, aged 44 years, who died after four months' illness. All the organs except the liver were fairly healthy. The liver was greatly, but uniformly, enlarged and of normal shape, smooth on the surface, firm on section, and mottled or nutmeg-like in appearance. The capillary spaces within the lobules were dilated and filled with proliferated endothelial cells, many of these being free and mingled with blood corpuscles. These cells varied in size and shape, some of their nuclei showing mitotic figures. The columns of hepatic cells were atrophied and compressed, the atrophy occurring mostly in the peripheral zones of the lobules. No fatty changes or iron deposits were seen in the hepatic epithelium remaining. The endothelial proliferation did not occur in nodules but was uniform throughout the whole liver, and in one place where a small cavernous angeioma existed the endothelium had taken on the same proliferative change. The very evident relation of the tumour to the vessels indicated a source of irritation connected with the blood, the tumour change seeming to originate in the same way as a specific inflammation. No metastasis occurred although many of the proliferated endothelial cells must have been conveyed to the general blood stream, as if such cells when conveyed beyond a certain sphere of influence ceased to proliferate so as to produce metastatic deposits. That sphere of influence must be the liver parenchyma in a state of more or less disordered activity.—Dr. W. Milligan showed: (1) A Temporal Bone from a case of Suppurative Middle-ear Disease with cholesteatoma, temporo-sphenoidal abscess, and septic encephalitis; (2) a Temporal Bone from a case of Epithelioma of the Middle Ear; (3) two Temporal Bones from cases of Fracture of the Base; and (4) specimens of Laryngeal Benign Growths.

Leeds and West Riding Medico-Chirurgical Society.—A meeting of this society was held on April 10th, Dr. J. Allan being in the chair.—Mr. R. Lawford Knaggs showed a case of Interscapulo-thoracic Amputation by Littlewood's operation performed for Chronic Axillary Suppuration.—Mr. W. Thompson showed a man two years after Removal of six and a half feet of Small Intestine which was Ruptured.—Dr. E. F. Trevelyan showed a woman, aged 59 years, in whom Tremor of the Left Hand, probably due to early paralysis agitans, had followed the Amputation of a Finger. Also a girl, aged nine years, with recovery from Meningitis following whooping-cough. The patient now suffered from vertigo.—Mr. J. F. Dobson showed a case of Diffuse Tuberculous Peritonitis which had been complicated by Acute Intestinal Obstruction. The patient was admitted in April, 1907, suffering from acute intestinal obstruction. On opening the abdomen the peritoneum was found to be thickly studded with miliary tubercle; the obstruction was caused by the adhesion of a coil of ileum to a breaking-down mesenteric gland. The adhesion was separated and the dislocated gut was opened and emptied of its contents; the opening in the gut was closed by suture; the diseased gland was enucleated from the mesentery. The patient was now in excellent health.—Dr. A. L. Whitehead showed a case of Chronic Otorrhœa, Mastoid Disease, Facial Palsy, and Labyrinthine Suppuration, with Cerebellar Abscess. Also a case of Optic Neuritis in One Eye, with Consecutive Atrophy in the other, following influenza eight weeks ago.—Mr. Alexander Sharp showed a case in which Severe Tuberculous Laryngitis had become practically healed under treatment by creasote internally, and the application locally of menthol in parolein, lactic acid, curetting, and galvano-cautery.—Dr. A. G. Barrs showed a case of Rheumatoid Arthritis, with Enlargement of the Spleen.—Dr. T. W. Griffith showed a man with Bilateral Facial Paralysis.—Dr. J. Gordon Sharp showed a case of Infantile Spastic Paraplegia in a boy, aged 12 years. He was a seven-months child and fits commenced when three days old.—Mr. H. Secker Walker showed a case of Detached Retina, probably due to sarcoma of the choroid.—Cases were also shown by Dr. W. H. Maxwell Telling, Dr. T. Churton, and Mr. Michael A. Teale.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on April 15th, Dr. L. W. Marshall, the President, being in the chair.—Mr. W. B. Blandy showed a man, aged 23 years, the subject of Thomsen's Disease. The symptoms of temporary stiffness of many of the muscles during voluntary movement had been present for eight years, the muscles themselves being well developed. His only surviving relative, a sister, also suffered from similar symptoms.—Dr. A. C. Reid showed three male patients, aged respectively 54, 35, and 60 years, who had suffered from varying types of Cerebral Syphilis during the last 12 months. In all there had been headache, vomiting, ocular paralyses, and changes in the fundus oculi, while in the third case the illness set in with a sudden apoplectiform attack and loss of consciousness whilst in the street. In this case severe laryngeal ulceration also occurred.—Dr. J. A. Waring read a paper on the Dangers and Evil Effects of Infant Binders, in which he condemned binders as harmful and unnecessary. Warmth was supplied better by loose clothing and support was not needed. The only justification for the use of binders was as a safeguard against rough handling, especially about the recently ligatured umbilical cord during the first two or three weeks. The constriction of binders was frequently responsible for such injurious effects as restlessness and loss of sleep, vomiting, inguinal and umbilical hernia, chest deformities, interference with free respiration which was of great importance where there was already pulmonary disease, and interference with the cerebral circulation leading to convulsions and other serious results. Such constriction was probably largely responsible for many of the cases in which infants were said to be overlain.—The paper was discussed by the President, Dr. W. Hunter, and Mr. W. Morley Willis.—Dr. Waring replied.

Brighton and Sussex Medico-Chirurgical Society.—A meeting of this society was held on April 2nd, Mr. H. H. Taylor, the President, being in the chair.—On the motion of the President a resolution of deep sympathy with the family of the late Dr. H. C. Lecky was passed.—Dr. J. S. Risien Russell read a paper on the Diagnosis of Intracranial Tumour, in which he reviewed seriatim the localising signs and symptoms of tumours of the brain in the various areas.

Medical Inspection of School Children.—At a recent meeting of the Gloucestershire county council it was decided that the county medical officer of health should be appointed to undertake the ordinary sanitary work of the county and also, with the aid of assistants, the medical inspection of the school children.

or most prominent part of the dorsal convexity or bump a broad band of webbing which passed laterally across the convexity and was attached to a horizontal iron bar fixed in the plaster bed. The convex ribs rested upon this band of webbing and were consequently continuously subjected to considerable pressure in an anterior direction. The influence of such pressure upon the dorsal convexity was enhanced by the recumbency of the patient and by the simultaneous extension of the vertebral column.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 13th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Dr. STCLAIR THOMSON showed two radiographs to illustrate the value of the x rays in showing and washing out the frontal sinus. He said that when unprovided with the x rays it was usual to depend upon the direction taken by the cannula to decide whether the frontal sinus had been entered or not. One of the radiograms showed that the point of the cannula passed up towards the frontal sinus and that the portion of it outside the anterior nares was flat against the upper lip. Those two points might make them think that the frontal sinus had been certainly entered, particularly when pus could be washed out. But on the x ray screen it could be seen that the cannula had not entered the fronto-nasal duct but had passed up into an anterior ethmoidal cell and that its point was pressed against the floor of the anterior fossa of the skull. It would readily be recognised that any roughness in manipulation in that area might have serious results. He showed another skiagram of the same case, with the same cannula, where the instrument was with the help of the x rays securely guided up into the centre of the frontal sinus. He also exhibited a radiogram showing complete absence of the left frontal sinus; it could be seen that the right frontal sinus was of exceptionally large size and crossed the middle line so as to occupy not only the right side but also the left side of the forehead. The condition, as revealed by the radiograph, was confirmed by operation. The case illustrated the great value of the x rays in showing the position and extent of the frontal sinus.

Dr. C. W. CHAPMAN showed a case of Bradycardia with Valvular Incompetence in a man 38 years of age. The patient was first seen by him in June, 1903. He had been passed as a first-class life at an insurance office in 1901. The first symptom noticed was in May, 1903, when he had an attack of giddiness followed by shortness of breath and a feeling of tightness in the chest. Later he had a second attack of giddiness, with dimness of vision. In September, 1903, the pulse-beat varied from 34 to 40, no abnormal sounds could be detected in the aortic region, a mitral systolic murmur was present though only heard during the stronger contractions, and all the cardiac beats could be felt at the wrist. In February, 1907, he was taken with a sense of severe constriction of the chest, followed by faintness and loss of consciousness. There had been attacks of transient dimness of vision and giddiness during the last year, otherwise he had been very well.—The PRESIDENT observed that bradycardia was not a condition inconsistent with prolonged life.—Dr. F. PARKES WEBER raised the question whether the affection developing in adult life was against the patient reaching an advanced age, and Dr. CHAPMAN pointed out that in the case which he brought forward the condition might be congenital with delay in the appearance of the symptoms.

Dr. F. S. PALMER showed a case of Progressive Muscular Atrophy in a boy, aged 15 years. The condition was most marked in the left upper limb, there being extreme wasting of the hand muscles and almost complete wasting of all the muscles of the limb. The hand was in the position of "main en griffe." Dr. PALMER, in reply to an inquiry from the PRESIDENT, said that an unusual point in the case was that fibrillary twitchings had commenced in the muscles of the shoulder girdle and not in those of the hand.

Dr. PALMER also showed a case of Articulatory Defect following attacks of Transient Hemiplegia.

Dr. PARKES WEBER showed a case of Primary (?) Splenomegaly with Anæmia. The patient was a Jewish married woman, aged 50 years, said to have come from a non-malarious part of Russia. The spleen was hard and greatly enlarged, reaching downwards into the iliac fossa, and reaching to the right across the middle line slightly to the right of the umbilicus. It was not tender to pressure. In January, 1908, a differential count by Dr. A. E. Boycott of the white cells in the patient's blood showed that in 500 cells the lymphocytes were 20·8 per cent., the intermediates 7·6 per cent., the large hyalines 4·4 per cent., the neutrophile polymorphonuclears 66·8 per cent., the eosinophiles 0·4 per cent., and the mast cells 0·0. Whilst counting the 500 white cells he saw 24 ordinary normoblasts, 16 erythroblasts which resembled megaloblasts except in their relatively small size, and three typical megaloblasts. He saw many polychromatophilic red cells, a few punctate basophilic red cells, and three megalocytes. The platelets were apparently increased in amount. Removal of the spleen would probably be advisable were it not for the obvious danger to life of such an operation in the present patient. It was possible that later the condition would develop into that of so-called "Banti's disease," with leucopenia and hepatic cirrhosis.

Dr. PARKES WEBER also showed a patient with an Enlarged Spleen and described the case as one of pernicious anæmia.

Dr. W. H. WILLCOX showed a case of Cirrhosis of the Spleen and Liver (? Banti's disease).

The PRESIDENT, in discussing the three cases of enlarged spleen, considered that in Dr. Parkes Weber's second case there must be some other condition present than pernicious anæmia, and Dr. F. J. POYNTON asked how many cases of pernicious anæmia with an enlarged spleen Dr. Parkes Weber had seen.—Dr. PARKES WEBER said that he had heard that enlargement of the spleen and of the liver occurred in pernicious anæmia but not always.

Mr. E. M. CORNER showed a case of Old Fracture of the Head of the Astragalus and the Scaphoid of the Foot in a man who had fallen 16 feet on to his foot as the result of an accident in July, 1907. He was "faint" and carried home, not standing on the foot. He remained in bed three days, after which he went about on crutches for three weeks. It was supposed that his left ankle was "sprained." Coming under the Employers' Liability Act there was great dissatisfaction because he recovered so slowly and could not work. The treatment consisted of massage, exercises, and the use of a pad in his boot under the arch of his foot. Under it he improved slowly, the foot not swelling so much, the man sleeping better and getting about better. In March, 1908, the insurance company referred him to Mr. Corner for an opinion as to why he did not get well. On examination, a bony swelling was found between the tubercle of the scaphoid and the internal cuneiform, such as was not present on the uninjured foot. This suggested a possibility of a fracture of the astragalus. Skiagrams were taken of both feet, which showed that "in the left foot there has been a piece broken off the inner side of the head of the astragalus and also a fissure fracture through the scaphoid, directed upwards and forwards, involving both articular surfaces, and showing little or no displacement." The broken-off part of the astragalus was seen by the lower part of the head, the fissure in the scaphoid beginning opposite it and being directed upwards. This case was an example of what might be called the "obscure fractures," undiscovered until the x rays demonstrated them.

Mr. CORNER also showed a case of Overgrowth of the Great Toe with Dislocation of the Metatarsophalangeal Joint. The condition was in part congenital and in part acquired, the congenital factor being the overgrowth of the soft parts and bones, the acquired factor being the abducted position of the toe due to wearing boots. As the man was perfectly satisfied there was no need to treat the condition.

Dr. O. K. WILLIAMSON showed a case of Aortic and Mitral Stenosis in a boy, eight years old. The heart's apex beat was found to be in the fifth left intercostal space half an inch outside the nipple line. At the apex both sounds were audible, the first being short. At and within the apex was heard a crescendo presystolic murmur. At the second right interspace both sounds were audible, also a harsh systolic murmur having its maximum intensity at this spot and being conducted up to the clavicle. There was no diastolic murmur. At the second left interspace the systolic murmur was audible and the second sound was markedly accentuated. The pulse was small, rapid, and regular; the vessel was full between the beats. Slight choreiform movements were present.

Dr. H. E. SYMES-THOMPSON showed a case of Bigeminal Heart in a single woman, aged 20 years. The apex beat of the heart was in the sixth space in the nipple data. There is one point in this chapter which might have been written otherwise and that is "that the foramen ovalis *is seen lying just below* and between the two limbs of the genu formed by the canal for the facial nerve." The part on Examination of the Patient is written very clearly but here again there is an anatomical error, for it is stated that the vessels of the labyrinth communicate with those of the tympanum through those of the inner wall of the middle ear, which we are under the impression is exactly what they do not do. On p. 121, in considering the treatment of chronic suppurative disease of the middle ear, the following prescription appears: "Politzerisation should be practised as a help in the evacuation of the discharge, which *is best done while the meatus is filled with hydrogen peroxide, which is thus sucked in and forced out of the* middle ear." We fail to understand how it is sucked in. On p. 180 the recognition of the diagnostic value of the so-called double negative Rinné is attributed to Lake. This is, of course, incorrect, as this important discovery was made by Professor Bezold of Munich. In the *treatment of the wound after operating for acute disease of* the mastoid the first dressing is advised to be performed within 24 hours. This certainly is erring on the side of safety, and in describing the radical mastoid operation one style of instrument is recommended for the right side and another for the left, which seems to us scarcely necessary or advisable.

Speaking generally, we think that notwithstanding the above criticisms this book is one which will be extremely useful to students and practitioners and which does credit to the author.

Manual of Ophthalmic Operations. By F. P. MAYNARD, M.B. Durh., D.P.H. Camb., F.R.C.S. Eng., Lieutenant-Colonel, Indian Medical Service; Professor of Ophthalmic Surgery, Medical College, Calcutta, &c. With six stereoscopic plates and 104 illustrations. London and Calcutta: Thacker and Co. 1908. Pp. 223. Price 9*s.* net.

UNTIL the publication recently of Grimsdale and Brewerton's Text-book of *Ophthalmic Operations* there was no work of importance in the English language devoted to this branch of ophthalmology. In reviewing this book we pointed out that it was a systematic treatise in which the opinions and predilections of the authors were kept severely in the back ground and that there was still room for an authoritative work, written from a more personal point of view, by an operator of extensive experience. Such a work is supplied in Colonel Maynard's manual. The author has benefited by the peculiar advantages of practice for many years in India; he has, moreover, availed himself to the full of the somewhat scanty opportunities which his position affords him for keeping abreast of the methods in vogue in England and on the continent. The result is a work of sterling value which may be safely recommended to the student and will be read with profit by every ophthalmic surgeon. The latter will appreciate the excellence of the general teaching, though he will doubtless discover details in Colonel Maynard's practice which will fail to meet with his approval. None of the latter, however, can be included under the opprobrious category of "fads." All have been adopted deliberately upon the basis of accurate knowledge of ophthalmology and ophthalmic pathology, and though individuals will differ as to the soundness of the deductions they will find little reason to quarrel with the facts upon which they are founded. We may cite as examples the author's routine use of atropine before extraction of cataract and of eserine immediately after iridectomy for glaucoma. The experienced ophthalmologist will probably be most interested in the chapter on expression of the lens in its capsule by the method of Major Smith, I.M.S. The author has somewhat modified his adverse criticism of the operation which was based upon 175 cases in which he performed it. He now holds that it is valuable in hypermature cataract and in some cases of unripe cataract.

The recently described operations of Professor Lagrange and Lieutenant-Colonel Herbert, I.M.S., for glaucoma receive attention; the latter, though in Colonel Herbert's own words, is almost unintelligible; we think that neither is yet of proved utility and like *cyclodialysis* should have been omitted. In extirpation of the lacrymal sac Axenfeld's retractor is used in an original manner; after considerable experience we are of opinion that it is a clumsy instrument which is best dispensed with altogether. We notice that Worth's advancement operation is chosen for description. If we had not found this to be the rule in recent publications we should not have considered it necessary to comment upon it. How many of the authors really adopt this method? In our opinion it is founded upon a fallacy and practical experience shows that it possesses notable disadvantages. The only novelty about the illustrations is the use of stereoscopic photographs. Considering the extreme difficulty of obtaining satisfactory photographs—doubtless less in India than in England—the results are gratifying. None the less, we do not think that they are worth the trouble and expense.

The book is well printed and is handy in size. We cordially wish it the success which we believe it fully to deserve.

Confessio Medici. By the author of "The Young People." London: Macmillan and Co. 1908. Pp. 158. Price 3*s.* 6*d.*

THE nameless author of this confession, or rather profession of professional faith and of faith in his profession, boasts that he has stolen *half of his title from* Sir Thomas Browne, and we can charge him with including in his plunder no mean measure of the quality of English medicine's *sweet philosopher.* Not that the matter or the manner of these essays owes direct inspiration to the physician of Norwich, but that in their pages, as in Browne's own stately prose, is manifest a ripe counsellor uttering words of convincing worth. The book forms another link of the right metal in the chain that binds medicine to letters; much of it is infused with true art no less than clear thought, although our author may not thank us for saying so, seeing that he has a measured warning for all who would woo the austere spirit of Practice (of which company he professes membership) lest they should be tempted to dalliance in the Palace of Art; but his phrasing of the very warning proclaims him free of that household no less than the whole tenour of his thought shows him one for whom a seat is set in the sterner hall of philosophy. His essays range over the whole career of medicine, chiefly as the general practitioner finds it, for the first is concerned with the voice that bids the boy enter upon its service, and the last with the inevitable mandate at which the man must leave all earthly things for a destiny, he would have us think, other than the speculations of Haeckel's school can tolerate. We commend the book to every student and every practitioner of medicine, for it contains advice which is above rubies, the strong, sane, and tender guidance of one who has himself trodden the thorny track. His style is well shown in two of his chapters, that in which he worships at the shrine of the genius loci of his own hospital and that in which his shrewd wit seeks to shatter with ringing blows the fetters of materialistic and monistic thought in which the "deserted maiden Psyche" is lying bound. With a right good heart does this debonair champion sally forth to do battle with the dragon of Deterministic degradation for her honour. This Confessor is a notable maker of phrases and we are tempted to quote from his store. Let these two suffice: "I know of one who said to of greenish grey mud, in which he observed some spindle-shaped bodies of about the size and shape of oats but slightly longer, which gave him the key to the problem. He admitted that he should not have known what they were unless he had seen them under different conditions a short time previously. One day when riding to the hospital in the morning he noticed on the horizon a long narrow dark cloud. By about 12 the cloud had reached the town and a dense mass of locusts was passing over and millions were settling on the ground, on the trees, and on the roofs of the houses. And when in about 36 hours the visitation passed on every blade of grass and every green leaf with the exception of a few noxious weeds had disappeared and the ground was as brown and bare as one of the streets of London. But, as the locusts ate, they had necessarily to defæcate and their stools consisted of spindle-shaped bodies which were composed of the fibrous indigestible parts of the grass matted together and also of the silicious spicules which were to be found in many grasses. He had noticed them lying about after the locusts had gone and had examined them and it was quite clear to him that those which had been deposited on the large expanse of barrack roof had become partly disintegrated and had been washed into the tanks with the first shower of rain. The specific gravity of the particles kept them in suspension for some time, so that they sank slowly, and it was evident that he had to deal with a case of irritant mechanical poisoning caused by the passage of the spicules through the alimentary canal, similar to, but not so severe as, the ground-glass poisoning of the Obeah man in the West Indies (or the diamond dust of the Egyptians). That this view was correct was shown by the sequel. He stopped the source of water-supply and utilised a surface well in the barrack yard, the water from which was carefully boiled. The roof and the gullies were cleaned and a considerable quantity of similar débris was found. The tanks were emptied and cleaned and the pipes disconnected until after the next heavy shower and the outbreak of dysentery ceased as abruptly as it had begun. It was an interesting illustration of the curious and unexpected problems of sanitation which had occasionally to be dealt with in the tropics, and the obvious lesson was that in localities where the water-supply was dependent on the collection of rain water, and where locusts occasionally paid a visit they should see that the pipes were disconnected until the excretory efforts of the insects had been removed.

Mr. J. CANTLIE observed that the epidemic resembled the "hill diarrhœa" in India which was sometimes ascribed to mica being present in the water after heavy rains in the hill country.

Dr. W. HARTIGAN said that a corresponding affection to "hill diarrhœa" was known in *Hong-Kong* where mica from disintegrated granite was no doubt a cause of diarrhœa after rain.

Fleet-Surgeon G. T. COLLINGWOOD, R.N., drew attention to the fact that lime carried by rain from the roofs of houses in Bermuda was ascribed as a reason for outbreaks of diarrhœa.

Dr. W. CARNEGIE BROWN pointed out that unless the first portion of water collected from roofs was prevented from entering the tanks it was impossible to avoid contamination of the water.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Town Planning and the Housing Bill.

A MEETING of this society was held on April 10th, Sir SHIRLEY F. MURPHY being in the chair.

Dr. FRANCIS E. FREMANTLE read a paper upon the Garden City, Rural Housing, and the Government. He claimed the Garden City as the pioneer in England of the town-planning movement, for it attacked the root of conditions inimical to public health on the only scientific plan by making it practicable and profitable to prevent to a large extent the creation of future evils, trusting to death and decay for the natural passing away of those that already exist. He insisted upon the importance of recognising the doctrine of linear extension as applied to towns, but with modern methods of communication the true method of urban development was along the tramway and railway and as soon as the industrial as well as the residential development of a town acknowledged this principle there would seem to be no limit to the gradual spread of towns, big and small, into the country, permeating it in all directions. In connexion with the obstacles which attended the erection of labourers' cottages in rural districts Dr. Fremantle expressed the opinion that the real difficulties lay in the depression of agriculture, which prevented an increase of wages, and in modern requirements of sanitation and decency. If, he said, the labourer could not pay more than 3*s*. a week for his cottage then the rates must be burdened to a sufficient extent to build him his necessary house—a certain proportion of the cost, representing the recent enthusiasm of the community, must fairly be charged on the public purse when other sources fail. When commenting upon the general provisions of the Housing Bill he said that the crux of the housing question was the efficiency of the executive authority and its officers, but the Bill in this respect left the machine locked. It gave no new responsibilities or duties to the county council but gave to one of its officers the power to extort information from a district officer by which the county council might take action under its previous powers that had hitherto largely been a dead letter. The Bill did nothing to remedy the palpable and crying anomalies of the position of district medical officers of health and inspectors of nuisances and was altogether framed upon wrong lines. The necessary reforms lay in the rearrangement of authorities and officers and duties so as to include in one reasonable and uniform service the whole administration of school and general public health.

The paper was discussed by Mr. MONTAGU HARRIS, Miss CHURTON, Dr. W. BUTLER, Mr. F. J. BURMAN, and Dr. W. A. BOND.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Butlin's Operation for Cancer of the Tongue.—Brachydactyly.

A MEETING of this institution was held on April 9th, Mr. T. H. BICKERTON, the President, being in the chair.

Dr. F. J. S. HEANEY reported a case of Malunited Fracture of Leg Bones on which he had operated twice. The fracture of the tibia was spiral and comminuted and in spite of careful treatment some 14 weeks after the injury the lower fragment of this bone was found united with the upper fragment of the fibula. The fracture was identical with one shown by Mr. Arbuthnot Lane in his recent work on fractures, and the same peculiar vice of union had supervened in both cases as well as in others that had come under observation. In the present case, union had been brought about by screwing and wiring. Dr. Heaney advocated operation in all such cases in the first instance.—Mr. G. P. NEWBOLT was of the opinion that all cases of compound fracture of the tibia and fibula should be operated on as soon as possible.

Mr. R. C. DUN reported a case of Acute General Peritonitis in a Child, aged four years, the result of perforation of a typhoid ulcer in the lower ileum. The sudden appearance of acute peritonitis was the first indication of illness. The diagnosis of acute appendicitis with peritonitis was made. At the operation no cause for the peritonitis was found. The child lived 12 hours after the operation and at the necropsy definite changes characteristic of typhoid fever in Peyer's patches were found. A small perforation through an ulcer was present four feet from the ileo-cæcal valve. Mr. Dun commented on the rarity of typhoid fever at that age and especially perforation, the fact that there were no symptoms of illness until the perforation took place, and the difficulty of making an accurate diagnosis in such a case.—Dr. N. P. MARSH thought it quite possible for a child to have an attack of ambulatory typhoid fever as met with in adults. He agreed that typhoid fever was very rare in children so young and especially perforation.

Mr. F. T. PAUL gave his experience of Butlin's Operation for Cancer of the Tongue and Mouth during the three years since Mr. Butlin's lecture had been published. The total number of cases was 35 (lip 3, cheek 3, palate 1, and tongue 28). Of these 11 were favourable in site and size, 15 were advanced, and 9 involved the bone. Of the favourable cases 9 were free from recurrence, 1 died from operation, and in 1, a slight case, no report was obtained. Of advanced cases 8 were free from recurrence, 1 had recurrence, 5 had died from it, and no report could be obtained in 1 case. Of the bone cases none were known to be free, 4 had recurrence, 1 died from the operation, 2 from disease, and no report was

THE LANCET.

LONDON: SATURDAY, APRIL 25, 1908.

The Research Defence Society.

WE publish in another column a letter from Earl CROMER announcing the formation of the Research Defence Society, of which he is the first President, and we have appended to that letter the names of the Vice-Presidents, which sufficiently show the powerful and varied nature of the support which the movement is receiving at its inauguration. It is to our mind absolutely necessary that the society should start under such fortunate auspices, for it is to act in an educational and advisory capacity in behalf of members of the public and members of the medical profession who want to know the truth about physiological and bacteriological work as pursued by the medical profession and the authorised investigators. Membership is open to everyone on payment of a small annual subscription, as is pointed out in Lord CROMER'S letter, and it is imperative that the public should feel that the sayings and doings of a society which extends so wide an invitation have their origin in a desire and a capacity to inform and derive no inspiration from prejudices. The society will do its utmost to counteract the copious inaccuracy of sentimentalists, the astonishing self-esteem of faddists, and the misguided and unrestrained zeal of certain agitators who never rest from their endeavours to prove that the scientific physiologist is a person of devilish cruelty, in which connexion it should be noted that among its members the names can be found of leading members of the Society for the Prevention of Cruelty to Animals. The publicity which much of the proceedings before the Royal Commission on Vivisection has already received has enabled the public to gauge the kind of evidence upon which the most serious accusations of inhumanity against physiological workers have been lightly founded, and the Research Defence Society should have no great difficulty in explaining to all reasonable folk on which side the truly merciful man is to be found.

The society has for its president the Earl of CROMER; it numbers among its vice-presidents the presidents and chairmen of 12 of the best known London hospitals, the secretaries of the Metropolitan Hospital Sunday Fund and the King's Hospital Fund for London, six bishops and four deans; such veterans of science as Lord AVEBURY, the Rev. Dr. DALLINGER, Sir NORMAN LOCKYER, Sir JAMES DEWAR, Sir JOSEPH HOOKER, Sir DAVID GILL, Lord ROSSE, Sir WILLIAM HUGGINS, Dr. HUGHLINGS JACKSON, Sir JAMES CRICHTON-BROWNE, and Sir HENRY ROSCOE; such famous professors as Sir GEORGE DARWIN, FRANCIS DARWIN, Sir E. RAY LANKESTER, and Sir WILLIAM RAMSAY, as well as the Regius Professors of Physic in the Universities of Oxford and Cambridge, and the Principal of the University of London; such well-known medical men as Sir SAMUEL WILKS, Sir FREDERICK TREVES, Sir JOHN BATTY TUKE, Sir JAMES REID, and Sir THOMAS SMITH; men of affairs like Lord STRATHCONA, the Duke of ABERCORN, the Earl of HALSBURY, Lord LINDLEY, Lord CLAUD HAMILTON, Lord BATH, Sir HERBERT MAXWELL, Lord ROBERT CECIL, Canon DUCKWORTH, and Sir ALFRED JONES; men of art and letters like Sir ALMA TADEMA, Sir A. CONAN DOYLE, and Sir LUKE FILDES. We make no attempt to give a larger selection of the names of those who have already promised adherence to the new association—the list is already fully representative of all that is best in medical science and medical organisation, professors and practitioners uniting with educational authorities and those responsible for the conduct of great charities in the intent to furnish the public with an opportunity of learning the truth about scientific teaching. The honorary secretary of the Research Defence Society is Mr. STEPHEN PAGET (70, Harley-street, Cavendish-square, London, W.), who will be glad to furnish all information as to the movement, and to whom scientific workers owe a heavy debt of gratitude for the energetic way in which he has worked for the formation of the new association.

We wish the society well. It has been founded for the spread of truth and not, as will be stated by interested persons, either for the promotion of vivisection or for the glorification of the physiological laboratory. We wish to lay particular stress on the educational advantages which the public will enjoy by being able to obtain accurate information upon the work of medical research. While medical science is advancing by gigantic strides and annexing in every direction departments of learning which were in times quite recent definitely allocated to other sciences, the public intelligence has not been standing still. The public has vastly improved in general knowledge and recognition of this fact is now incumbent upon the medical profession. The half knowledge of scientific truths which so many now possess ought not to be exploited perpetually either by sentimentalists or agitators without an honest attempt being made by scientific men to explain the reasons for their faith and their actions. The Research Defence Society is already issuing pamphlets and leaflets upon different subjects, and will be a source from which accurate information can be drawn by lecturers, public speakers, and humanitarians. When this is found to be the case serious audiences will not be forthcoming who can be swayed by the clamours of the avowed enemies of medical science. The dark deeds of our medical schools, the ineptitudes of our medical men, and the futilities of accepted medical practice will continue to be dwelt upon by a certain class of lecturer for some time to come—indeed, the formation of the Research Defence Society will be the signal for an outburst of this kind of activity—but the audience will no longer be made up of intelligent units. The audience will be the credulous and the ill-informed, for the properly educated public will see where truth lies and it is the aim of the Research Defence Society to educate the public.

dangerous? or What would be the fate of this man with an irregular heart? The third platitude was to treat the patient and not the disease. Of course all medical men agreed with that, but if they just analysed their treatment for one day they would find that in the majority of cases they rather treated the disease. The "x disease" was a name which he had applied to a well-marked congeries of symptoms which he thought should not be dubbed neurasthenia as this name cloaked our ignorance and tended to prevent a proper spirit of inquiry. The person suffering from this condition was generally spare and thin, with livid face, cold hands, and other evidences of a weak circulation. Some slight pelvic, stomachic or other visceral lesion was often present and attacks of minor ailments were frequent from which the patient quickly recovered. The patient had often a mental "twist," was very introspective, and generally was a faddist (religious or dietetic) with strong opinions and beliefs. The condition was often quickly cured, possibly by (1) an appeal to the reason; or (2) by some strong emotion; (3) frequently by pregnancy; or (4) by some marked change in the mental outlook or mode of life. The President hoped that by this ridiculous name medical men might be reminded of their ignorance of its pathology and stimulated to research.—Mr. A. E. Maylard, in conveying to the honorary President the cordial thanks of the society for his most interesting address, referred in particular to the originality of mind and the keenness of observation which were manifested throughout and hoped that they would have much more work from Dr. Mackenzie and that he would live long to give it.—The President briefly acknowledged the vote of thanks.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on April 10th, Dr. E. Hobhouse being in the chair.—Mr. Hugh Lett read a paper on a Case of Henoch's Purpura associated with Intussusception. The patient, a child, aged three years, was quite well until two days before admission to hospital. He then had pain and swelling of the left knee and elbow. On the next day both legs were swollen and severe paroxysms of abdominal pain were experienced. On the same afternoon two purpuric spots were seen on the left leg. The patient was admitted on the following morning and a cæcal intussusception was operated upon and reduced. The purpura steadily became worse and the patient died from a second intussusception of the enteric variety nine days after the first operation. Mr. Lett drew attention to the difficulty which was often met with in diagnosing between intussusception and Henoch's purpura when the abdominal symptoms appeared before the onset of any cutaneous lesions and also to the difficulty of deciding in many cases of undoubted Henoch's purpura whether an intussusception were present or not. He indicated the main points in the differential diagnosis between the two conditions and laid stress on the importance of determining the presence of a tumour before making a diagnosis of intussusception. The paper was discussed by Dr. G. A. Sutherland and Mr. Duncan C. L. Fitzwilliams.—Dr. J. Porter Parkinson read a paper on a fatal case of Tetanus Neonatorum in an infant aged two weeks. The infant had had the umbilicus dressed with fuller's earth and it was suggested that this might have been the cause of infection both in this child and also in the previous child who had died from tetanus. Dr. Parkinson drew attention to the prevalence of this practice and to the fact that this possible source of tetanus was well recognised by coroners. He thought the knowledge of this should be more widespread.—Dr. L. G. Guthrie showed a case illustrating Eustace Smith's Bruit. The patient was a boy aged seven years. The superficial veins were enlarged over the front of the chest. An undulating musical venous bruit could be heard at the base of the heart, occupying the whole of the cardiac cycle. The bruit was intensified and the venous engorgement became more pronounced when the head was retracted. The condition was probably due to pressure of enlarged mediastinal glands on the innominate vein or superior vena cava.—Dr. F. S. Langmead also showed a case with Eustace Smith's Bruit. The patient, a girl, aged five and a half years, had had whooping-cough in April, 1907. Since then she had had frequent coughs which were neither laryngeal nor paroxysmal. There was some impairment of note in the interscapular region on the right side. To the right of the manubrium sterni a definite to-and-fro rushing murmur was heard when the head was retracted, but it was lost when the head was flexed.—Dr. Porter Parkinson showed a case of Aortic Regurgitation in a boy aged four years. There was no history of rheumatism or other acute specific fever.—Dr. George A. Carpenter showed a case of Recovery from Encephalitis in a girl aged one year and eight months. The patient had had screaming fits, double optic neuritis, and squint. The cerebro-spinal fluid was sterile and contained no cellular elements. The optic neuritis disappeared.—Mr. A. Hamilton Burt showed a case of Hypospadias.—Specimens were shown by Dr. Hobhouse, Dr. E. Cautley, Dr. Carpenter, and Mr. John Poland.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on April 10th, Dr. A. J. Wallace (Liverpool), the President, being in the chair.—Dr. Alexander Stookes (Liverpool) exhibited specimens of: (1) Fibromyoma Uteri; and (2) Adeno-carcinoma Corporis Uteri which had given rise to similar physical signs. The former had occurred in a patient, a II.-para, aged 43 years, who had suffered for two years from menorrhagia and for the last four months had had continuous bleeding. A nodular tumour could be felt in the lower abdomen and per vaginam a polypoid mass occupied the cervical canal. The growth proved to be multiple fibromata. The second specimen occurred in a single woman, aged 51 years, who had enjoyed good health until 18 months previously, when she began to have severe pains in the left side and menorrhagia. These symptoms persisted. An irregular, hard tumour was felt in the lower abdomen which on abdominal section proved to be the uterus enlarged by adeno-carcinoma involving the entire thickness of the uterine wall. The right ovary was also the seat of adeno-carcinoma. Recurrence with a fatal result occurred four months after the operation.—Dr. Henry Briggs communicated a case of Pelvic Kidney with Congenital Absence of both Müllerian Ducts occurring in a patient, aged 33 years, who had been married for one year and who complained of occasional, never periodic, pain in the lower abdomen and slightly increased frequency of micturition. She had never menstruated. He gave an accurate anatomical description of the kidney as revealed at an exploratory operation.—Dr. Arnold W. W. Lea (Manchester) narrated a case of Dermoid Cyst of the Mesentery in a woman, aged 39 years, and showed the specimen and sections of it obtained by operation. The cyst was lined by large multinucleated cells but did not show any specialised epithelial elements.—Sir William J. Sinclair (Manchester) read a paper on Analgesia *versus* Anæsthesia in Obstetrical and Gynæcological Practice. After a brief historical review he referred to the method of spinal anæsthesia produced by cocaine and its derivatives, and to the inadvisability of such procedure in obstetrics. A few years ago great successes were reported from the lying-in hospitals of Germany from small doses of scopolamine, but this was not without real danger both to mother and child. He advocated the use of a combination of morphine, alcohol, and cocaine as an analgesic in minor gynæcological operations and in such manipulations as the removal of retained placenta following abortion, &c. He gave two ounces of alcohol, masked by the liquid extract of liquorice, about two hours before operation, followed by a hypodermic injection of a quarter or half a grain of morphine 20 minutes before the operation. The vagina was then swabbed with a 10 per cent. solution of cocaine. By this method any minor operative procedure was possible. The amount of morphine required modification according to the type of patient. In some cases where a general anæsthetic was necessary the amount required was exceedingly small if morphine and alcohol were previously administered.—Dr. A. Kynvett Gordon (Monsall) and Dr. Lea both spoke in favour of this method from their own experience of it.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 2nd, Dr. G. Thomson, the President, being in the chair.—Dr. Arthur J. Hall showed the following: 1. A girl with a very Moveable Liver. On deep inspiration the lower edge was tilted forwards and formed a prominent tumour. 2. A similar case in an adult woman. 3. A case in which the diagnosis between Herpes Zoster and Herpes Febrilis was difficult. The eruption recurred every three months in the region supplied by the second division of the fifth nerve. 4. A patient with a Cavity in his Lung and much Offensive Sputum, which had been repeatedly examined for tubercle bacilli with negative results. Dr. Hall demonstrated by means of charts the effects of Chaplin's creasote inhalation method, which had been highly successful.—Dr. H. G. M. Henry the signs of disease in the writers and the artists whose respectable conformity to outworn models endears them to the Philistine than in the revolutionary propagators of new ideas and new methods. At all events, the fact—for fact it assuredly is—that insanity is much more prone to produce in art what is commonplace than what is original may perhaps be borne in mind with advantage by those critics who are so ready to brand as morbid and decadent every artistic development which conflicts with conventional models.

Plague in India.

THE great Powers of the world may consider themselves fortunate in that none of them have had such a factor to face as that with which our own great dependency of India has been struggling now for 12 years. In 1896 plague was introduced into Bombay from Hong-Kong and from Bombay it has spread gradually to the other provinces of the country. The deaths have gradually risen; there were 1704 deaths in 1896, 56,056 deaths in 1897, 577,427 deaths in 1902, and 1,178,989 deaths in 1907. In all up to May, 1907, 5,402,245 deaths have been caused by this dire disease; and to show what this means we have only to remember that the total population in India is about 300,000,000, so that this mortality means about one death in every 60 inhabitants. It must be evident therefore at once that a pressing problem confronts India, for not only has the disease unfortunately of late years affected the territories of the peninsula whence we obtain our most valued recruits, but if left, as Professor W. J. R. SIMPSON so well points out, to take its own course, as it has been within recent years, it will become a danger to the world. That the problem of its suppression and extinction is not an easy one is at once evident when we take into account the peculiar environment present in India. We have here an essentially conservative people who are naturally prone to view with suspicion and aversion any new device sprung upon them. We have also a people imbued with a reverence for animal life, so that one of the chief methods of plague prevention—viz., the destruction of rats—is viewed with dislike. Of the modes of prevention hitherto employed some have been attended with scant success. In the articles on Sanitary Reform in India which have appeared lately in THE LANCET old history has been necessarily dealt with; the time is therefore appropriate to see where we stand now. Captain W. GLEN LISTON, I.M.S., member of the Plague Research Commission and acting director of the Bombay Bacteriological Laboratory, Parel, in December last delivered a most interesting lecture before the Bombay Sanitary Association on the cause and prevention of the spread of plague in India, and we have also to guide us the illuminating Croonian lectures of Professor SIMPSON, one of the greatest living authorities on plague, delivered before the Royal College of Physicians of London. Let us briefly examine the course of action recommended by these experts. Plague is essentially a rat disease as defined some three years ago by the first of the above writers. The Plague Research Commission, of which he was a member, has conclusively proved that rats are the chief source from which man acquires plague and has also afforded the strongest possible grounds for inferring that man becomes infected through the agency of rat fleas which previously to biting him have fed upon infected rats. This officer, in the lecture referred to, first showed how the association of rats with man was the cause of epidemic plague and how this association was dependent on the habits of rats and on the customs of the people. He divides rats into field rats and house rats, and then shows that the latter are of prime importance so far as man is concerned, and that, of these, the Mus rattus, from its remarkable domestication, is the most important plague-spreading rat, as was proved by the Plague Commission. The plague amongst Mus rattus precedes the plague amongst man by an interval of a week or a fortnight. Next the author proceeds to show how the habits of the people favour the multiplication of rats; how the structure of their houses affords shelter to rats; how, again, the mode of residence in these buildings brings about an association of rats with man, as exemplified, for instance, in the cases where baskets or open sacks of grain are often left uncovered at night in the shops so that the rats gain a ready access; again, the same event is brought about by the inhabitants storing up grain and grocers' materials in their ground and upper storeys. The very streets are habitually used as a depository for filth and refuse, and thus afford a food-supply for these animals; cows, goats, and hens kept in human dwellings attract them. The above environment will be found throughout India. The infected rat now transfers its infection by the rat flea to man.

Hence in the prevention of plague we have primarily to cope with the rat. That destruction of rats where thorough will accomplish this has been proved in many instances; we may mention, for example, the case of the Punjab; here in 1906 evidence was obtained from 18 centres of endemic plague; in 11 of these, where the destruction of rats was thoroughly carried out, there were no cases. In the first place, however, measures must be brought into play which aim at decreasing the food-supply and shelter afforded to these animals; regulations should be made preventing the erection of flimsy and ill-made buildings, and also insisting on the maintenance of the houses in a proper state of repair, for if not these houses will be found to afford shelter to rats. Dwellings must be kept free from grain stores, godowns, and stables; the public streets must not be used as depositories for food refuse; and tenants must be compelled to maintain their dwellings in a clean and tidy state by the health departments in the cities. Such measures will doubtless be difficult to enforce amongst the ignorant conservative people of India, but Captain LISTON wisely recommends their commencement in the larger towns where education is somewhat advanced. These being purged of the blemishes above described the villages will be directly benefited, for the cities are the great distributing centres of the disease. In the meantime the villagers should insist on a modified form of quarantine and should prevent those who have come from infected places entering their village until they have freed themselves from all fleas on their persons or kits. With this policy of the exclusion of rats must also be employed that of the destruction of rats, and a noteworthy method of accomplishing this is not by means of chemical poisons or by the dissemination of bacterial diseases amongst them, but by trapping them alive and then destroying them. Captain LISTON shows how in a certain village the rat population was reduced by this

Reviews and Notices of Books.

Text-book of Otology for Physicians and Students. By F. BEZOLD, M.D., Professor of Otology, Munich; and F. SIEBENMANN, Professor of Otology at Basle. Translated by J. HOLINGER, M.D., Chicago. With 75 figures. Chicago: Colegrove Co. Pp. 314. Price $3.50 net.

THIS is a translation of the work which we reviewed last year and there can be no doubt that a translation of it should be of extreme value to all English-speaking otologists. Unfortunately, however, the translation which we are considering, although in the main good, is in parts so inaccurate that were a beginner in otology to take it as his chief authority without having recourse to the original German he would be liable to fall into grave errors, even anatomical ones. On p. 13 of the translation the long process of the incus is said "to extend upwards and backwards in a vertical direction," a thing in itself impossible, the word "backwards" being gratuitously inserted. Again, on the same page the "cupola of the cochlea" is said to "rest against the tympanic end of the osseous Eustachian tube, whereas it should be "it borders on the commencement of the bony inner wall of the tube." On p. 14 the word *Krankheitserscheinungen* is translated "diseases," whereas it should be "symptoms." On p. 15 we meet with more anatomically incorrect translations. The facial nerve is said "to run mostly on the inside of the temporal bone," instead of that "the trunk of the nerve lies chiefly within the temporal bone." Again, on the same paragraph it is said that the "canal of the facial nerve forms a horizontal protuberance on the inner wall of the aditus, just above the oval window." No comment is needed on this. In one of the most important chapters in the book, Chapter VIII., on the Testing of Hearing, in the second paragraph it is stated that "it is fundamentally important for our examination of the function of hearing that all noises can be placed in the line of the sound scale. We have therefore completely examined the hearing as soon as we know quantitatively the hearing for all tones, and do not need to care for the noises." We feel convinced that this paragraph will convey but little to any reader. It would have been better rendered: "Going through all the sounds of the scale is fundamental for our examination of the hearing function. For in these cases, if we have thoroughly tested and established the qualitative hearing power for the whole series of tones, no further investigation of sound is necessary." On the same page we read that by certain methods "any audible number of vibrations," and so on. This should read "any number of audible vibrations." The mistakes in translation and composition are frequent but we can allude to only a few more. For instance, on p. 66 the word "improvement" is used with regard to bone conduction instead of "prolongation." On p. 70 we find the "prolongation of bone conduction above the normal interchange of the sound conducting apparatus was accepted in our discussions as a fact pure and simple, which we met with in all our observations," whereas this sentence should have concluded "which we continually met with in our observations."

From the foregoing examples it must be obvious that, valuable though the translation will be to those whose knowledge of German is not sufficient to allow them to read the original text but who have sufficient acquaintance with the subject matter to be able to recognise inaccurate translations, and knowledge enough of German to work out the correct translations where necessary, this translation, if accepted as correct, must be conducive to erroneous conceptions. We sincerely hope that the translator will carefully revise his rendering of this work, which is of inestimable value, so that it shall be both more readable in places and more accurate. Of the subject matter we have nothing to add to our previous remarks on Professor Bezold's work.

Diseases of the Digestive System (Modern Clinical Medicine). Edited by FRANK BILLINGS, M.D., Professor of Medicine, University of Chicago, &c. An Authorised Translation from "Die Deutsche Klinik," under the general editorial supervision of JULIUS L. SALINGER, M.D. London: Sidney Appleton. 1907. Pp. 824. Price 25*s.* net.

THE volume before us contains a series of articles written by eminent authorities in Germany and Austria upon matters connected with the digestive system. It opens with a contribution on Stenosis of the Œsophagus, by Th. Rosenheim of Berlin, followed by a series of articles on Gastric Disorders, W. Fleiner of Heidelberg writing on Gastric Lavage; H. Leo of Bonn on Functional Disorders of the Stomach; H. Strauss of Berlin on Secretory Disturbances; F. Riegel of Giessen on Gastric Dilatation; C. A. Ewald of Berlin on Gastric Ulcer and Hæmorrhage; and J. Boas of Berlin on Gastric and Intestinal Carcinoma. F. Hirschwald of Berlin deals with Displacements of the Abdominal Viscera and L. Oser of Vienna writes a very brief account of Diseases of the Pancreas. Jaundice and Hepatic Insufficiency are dealt with by O. Minkowski of Cologne; Chronic Inflammation of the Liver, by E. Stadelmann of Berlin; Neoplasms of the Liver and Biliary Passages, by Fr. Kraus of Graz; Echinococcus of the Liver, by Stadelmann; and Gall-stones, by Neusser of Vienna. Acute Peritonitis, Diffuse and Circumscribed, including Perityphlitis, is discussed by O. Vierordt of Heidelberg, and Chronic Perityphlitis, by Boas who also treats of Constipation and Hæmorrhoids. An account of the Methods of Examining the Fæces is given by J. Strasburger of Bonn; and Diarrhœa, Intestinal Catarrh, and Intestinal Tuberculosis are dealt with by Fleiner. G. Hoppe-Seyler of Kiel writes on Mucous Colic and Membranous Intestinal Catarrh and the book ends with an account of Intestinal Constriction and Occlusion by H. Nothnagel of Vienna.

The foregoing array of distinguished names sufficiently indicates that the book contains valuable matter. It is not, and does not profess to be, a complete and systematic textbook of the subject with which it deals, as it is easy to point out matters of importance, such, for example, as tuberculous peritonitis and the various forms of gastritis which are entirely omitted. The translation is of about the usual degree of merit found in American translations of German works. It is intelligible but not elegant, and here and there we meet with curious expressions, as, for example, "the abdominal press" for the intra-abdominal pressure, "its inclosure, the appendix" for the organ which incloses it (a calculus).

On the whole, the book is interesting and useful as illustrating contemporary continental practice, which differs in some points from that usual in this country—such differences lying in the views prevalent on subjects such as the need for immediate operation for appendicitis and the early use of gastric lavage. Discussion of opposing ideas cannot fail to be stimulating and valuable, as the last word has not been said on many points which are too readily accepted as settled by dogmatic assertions.

A Short Practice of Aural Surgery. By J. ARNOLD JONES, M.B., Ch.B. Vict., Assistant Aural Surgeon to the Manchester Eye and Ear Hospital. With 25 figures. London and New York: John Lane. 1908. Pp. 246.

THIS little work, produced by a young aural surgeon, is one which possesses the great advantage of being written in a very readable way. The first chapter is devoted to a short *résumé* of the more important anatomical and physiological uttered didactically; and (3) twaddle; whilst Dr. Mackenzie's own definition was "a statement of ignored trifles or things taken for granted." We can certainly acquit his platitudes of having any part in the dictionary's final alternative, and if we accept the other two definitions in this special connexion, truth, no less than courtesy, demands the deletion of their contemptuous adjectives. Combining, then, our modified authority with the meaning which Dr. Mackenzie himself gives to a platitude, we may define it as "a statement which is so true as to be obvious, dealing with things so commonplace as to be taken for granted and which have consequently come to be ignored as trifles." We submit that this meaning puts a different complexion upon the despised platitude, and even though we allow our dictionary to add that it is "uttered didactically," may not such formal delivery invest its lesson with a force lacking in casual utterance? We are prepared to justify our defence of platitudes by quoting the three on which Dr. Mackenzie based the paper in question: "Carefully observe your patient and understand what you see." "Treat the patient and not the disease." "Observe what becomes of your patients." How often has young Laertes, M.B., freshly "capped and doctored and a'," listened to such platitudinous counsels from the tedious lips of Dr. Polonius, his professional father! Oh yes, he's heard all that a hundred times and only wants to be spurring on his way. And yet, if he ponder upon this trilogy of truisms (of which, by the way, the third deserves more attention than it generally receives), he may fuse them into a golden rule for the practice of medicine, a very compendium of its science and art. It is, as Poe insisted, the name writ largest on the map which we fail to find, the obvious which escapes our attention, and it is well to be now and again formally reminded of the importance of the commonplace principles upon which experience shows we may best conduct the business of our lives. And a platitude has this great claim to respect, that granted it embraces a truism, *a fortiori* it contains a truth, and in the practice of medicine the establishment of an unassailable fact raises a new rock of safety out of a shifting quicksand. The man who can find nothing but tedium in the contemplation of such platitudes as we have quoted, if asked his candid opinion of Newton's statement of the laws of motion, would not improbably confess that to his intelligence they appeared a somewhat pedantic expression of obvious natural phenomena, in fact, mere dynamical platitudes. It would never occur to this superior person that had the philosopher not embodied his observations in convenient formulæ the knowledge of these phenomena would not have been his own birthright. And so it is with the platitude, for which, in place of the dictionary's scornful utterance, we now venture the more respectful and handier definition of "crystallised experience."

URBAN MORTALITY IN IRELAND.

THE recently published yearly summary of the weekly returns issued by the Registrar-General for Ireland during last year records a rate of urban mortality in that part of the United Kingdom in marked excess of the rate that prevailed during the same period in the principal urban population of England and Wales. In the 76 large English towns, each having an estimated population exceeding 50,000, the mean rate of mortality during last year did not exceed 15·4 per 1000, while in London, with a population little short of 5,000,000, the unprecedentedly low death-rate of 14·6 per 1000 prevailed. The return referred to contains statistics relating to 22 town districts of Ireland, with an aggregate estimated population of little more than 1,000,000; and the population of the individual town districts ranged from 300,850 in Dublin city and 370,163 in Belfast, to 7909 in Queenstown and 7588 in Armagh. Indeed the population of but three of the Irish towns exceeded 50,000, while in each of 16 of the 22 town districts the population was considerably below 20,000. Notwithstanding, however, the inclusion of so many small towns in the Irish list the mean rate of mortality in the 22 town districts during last year was equal to 21·1 per 1000, exceeding the rate in the 76 far larger English towns by no less than 5·7 per 1000; thus the rate of mortality in the Irish urban population exceeded that in the principal urban population of England and Wales by 37 per cent. The contrast between the London and Dublin death-rates was still more startling. The recorded rate of mortality in the Administrative County of London during last year did not exceed, as is stated above, 14·6 per 1000; whereas in the Dublin registration area the death-rate was equal to 24·2, thus exceeding the London rate by 9·6 per 1000, and by no less than 66 per cent. Moreover, this excessive death-rate in Dublin was 1·1 per 1000 below the average rate during the ten preceding years. It is also worthy of note that the death-rate last year was equal to 21·3 per 1000 in Belfast, and that among the smaller Irish towns it exceeded 20 per 1000 in Cork, Galway, Kilkenny, Newtownards, and Waterford. These high rates of mortality in the Irish towns can only reflect the defective health condition of the urban population which calls for careful investigation. It is only possible here to note one or two facts disclosed by this summary of the Irish weekly returns. In the first place, it is clear that the excessive rate of mortality in the Irish towns is not due to exceptional fatality of epidemic disease, as the rate of mortality during last year from the seven principal epidemic diseases was identically the same—namely, 1·6 per 1000, both in the 76 English towns and in the 22 Irish town districts. It is true that the rate of infant mortality, which did not exceed 127 per 1000 births during last year in the English towns, was equal to 135 per 1000 in the Irish towns; this excess of infant mortality, however, accounts for but a small proportion of the excess in the crude death-rate in the urban population of Ireland. As the birth-rate last year in the Irish towns was equal to 28·4 per 1000, against 27·0 in the English towns, it is improbable that the excess of mortality in the former is due to any very exceptional age constitution of the population, but it may be pointed out that while the proportion of deaths of persons aged upwards of 60 years to total deaths did not exceed 26·5 per cent. in the Irish towns, it was equal to 29·2 per cent. in the large English towns. These figures appear to suggest that the main excess of mortality in the Irish towns occurs among adults aged between 20 and 60 years. The true explanation, however, of this excessive mortality is not disclosed by the Irish Annual Summary under notice, and could only be ascertained by a full and careful analysis of more detailed statistics of the mortality in this Irish urban population, at various groups of ages and with due regard to its sex and age constitution.

THE EXISTENCE OF FORMS OF THE TUBERCLE BACILLUS WHICH ARE NOT ACID-FAST.

THE existence of forms of the tubercle bacillus which become decolourised in the course of the ordinary Ziehl-Nielsen method of staining is affirmed by Dr. Hans Much of Hamburg, in an interesting paper published in the *Berliner Klinische Wochenschrift* of April 6th. He has found that on making post-mortem examinations of cattle infected with tubercle bacilli of known origin and of ordinary characters, and presenting typical nodules in the lungs, the most careful examination may in certain cases fail to reveal ordinary acid-fast tubercle bacilli, in spite of the fact that inoculation experiments may demonstrate the tuberculous nature of the lesions and that from some of the cases tubercle bacilli may be obtained by culture. Similar results [illegible] observed with a friend, *I don't want my doctor to talk to me about the National Gallery:* which is a shrewd saying. People who are seriously ill care no more for preciosity in us than for gold dust in the beef-tea." And again: "Hospital letters are a survival of the bad Georgian way of *patronising the unfortunate.* Nothing can justify them, unless it were the existence of people who would not subscribe even to the maintenance of Heaven, without an Annual Report and the right to recommend four souls for immediate admission, if found suitable cases." One word more. Our author knows his Juvenal and makes such apt employment of his Shakespeare that we should welcome from his pen a set of essays frankly concerned with the interpretation of the Master's mind. It may seem a bold thing to urge the further tilling of that well-cultivated field, but the author of "Confessio Medici" has the stuff in him that, if we are not mistaken, might well enhance its fruitfulness.

LIBRARY TABLE.

The Cottage on the Fells. By H. DE VERE STACPOOLE. London: T. Werner Laurie. 1908. Pp. 306 Price 6s.—Mr. Stacpoole in his most recent work has made quite a departure from his previous book, "The Blue Lagoon," that charming idyll of the South Seas with its delicate flavour of Theocritus XXVII., or perhaps we should rather say the Daphnis and Chloe of Longus. "The Cottage on the Fells" is a story of a murderer who was a genius in his horrible way. We will not give away the plot but it is a good one and the mystery is kept up till the end. There is one point where we think Mr. Stacpoole must have been nodding and that is in Chapter XXIX., where the motor-car of the director of the Criminal Investigation Department which is taking him to a road near Holland House goes from Scotland-yard all the way round by Regent-street, the Bayswater-road, Silver-street, and Kensington-road. As the director was in a hurry this seems inexplicable. Why not have gone by Piccadilly? There is nothing medical in the book but that is all the more reason why medical readers will find in its pages welcome relaxation from professional study.

Lessons in Practical Hygiene for Use in Schools. By ALICE RAVENHILL, F.R San. I., late Lecturer on Hygiene and Inspector, County Council, West Riding of Yorkshire; Lecturer, University of London Extension Board. With Preface by Professor M. E. SADLER, M.A. Leeds and Glasgow: E. J. Arnold and Son, Limited. 1907. Pp. 750. Price 5s. net.—This is far more than a work on elementary hygiene. It is divided into five parts and ranges over an extensive series of fields of study such as the requirements, phenomena, and characteristics of life, the conditions by which life is affected, air and water. Nearly 200 pages are devoted to the human body; about 170 to food and foodstuffs, cooking, beverages, and food preservation; about 60 to personal hygiene; and 120 to the dwelling in all its aspects. Many of the chapters contain much that is far outside the scope of the sixth standard child. Careful lists of apparatus and materials required are given, while full directions are furnished for the performance of experiments. It is not a textbook in the ordinary sense of the term to be placed in the hands of the pupil. It appears to us to be rather a guide to, and most useful quarry of, information from which the teacher can select material for his lectures. It is throughout thoroughly practical but the number of experiments given is so large that no single scholar could overtake them. It will prove a most useful source of information to teachers of hygiene and indeed to teachers of elementary physiology in secondary and higher schools. It is excellent throughout and is a trustworthy guide to practical hygiene, while its price brings it within the reach of all.

First Aid to the Injured: Six Ambulance Lectures. By the late Dr. FRIEDRICH ESMARCH. Translated from the German by H.R.H. PRINCESS CHRISTIAN. Seventh edition, revised and enlarged, with additional illustrations. London: Smith, Elder, and Co. 1907.—The first English edition of Dr. Esmarch's lectures on ambulance work was published by the Princess Christian in 1882, and the appearance of a seventh edition 25 years later is a good guaranteee of the favour with which it has met. The favour has been deserved, for it is well written and clearly arranged and the translation is worthy of its author. We can safely commend it to all who are engaged in ambulance work or lecturing. Some of the old pictures which illustrate the book appear somewhat quaint at a day when we are accustomed to elaborate photographic reproductions, but new illustrations have been added and though the old blocks are a little the worse for wear they serve their purpose well enough.

Aids to Surgery. By JOSEPH CUNNING, M.B., B.S. Melb., F.R.C.S. Eng., Surgeon to the Victoria Hospital for Children; Assistant Surgeon to the Royal Free Hospital. Second edition. London: Baillière, Tindall, and Cox. 1908. Pp. 404. Price, paper, 3s. 6d.; cloth, 4s. net.—This is the second edition of a little revision book for students about to be examined in surgery, which we reviewed when it first appeared (THE LANCET, March 26th, 1904, p. 878). We then said that it was an excellent product of its class and although all such books must owe a great deal to larger works yet they have a distinct use, provided they are not abused. A few pages of the book have been rewritten. The information is sound and the book seems likely to become in surgery much the same as "The Pocket Gray" has become in anatomy. We note that the present edition, although larger than the first, is slightly cheaper in price.

The Pocket Anatomy. Sixth edition, revised and edited by C. H. FAGGE, M.B., M.S. Lond., F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1908. Pp. 269. Price 3s. 6d. net. —The little green covered book which has been carried about by many generations of students at the time when they are preparing to face their examiners in anatomy, and which has declared its normal *habitat* under the title of "The Pocket Gray," is to be known in future as "The Pocket Anatomy." Mr. Fagge in his preface states that his reason for the change of title is that he has borrowed from the works on anatomy by Quain, Cunningham, and Morris in compiling this edition, so his revised title is well justified. As we have often said, this class of book can be used and abused—it may be either a revision book or a cram book—but "The Pocket Anatomy" in intelligent hands is, we consider, an extremely useful little book. We see that Jonesco's description of the pelvic colon is given and the term "rectum" is restricted to that portion of the gut to which it is rightly applicable. The book is carefully indexed.

A Manual for Hospital Nurses. By E. J. DOMVILLE, L.R.C.P. Lond., M.R.C.S. Eng. London: J. and A. Churchill. 1907. Pp. 152. Price 1s. 6d. net.—We need say little about this book beyond recording the fact that it has reached its ninth edition, which is a guarantee of its popularity. It is an elementary book on nursing, intended for both nurses in training and others engaged in attending on the sick, and it briefly covers the usual ground in an adequate manner.

HEALTH OF BOURNEMOUTH.—Mr. P. W. G. Nunn, the medical officer of health of Bournemouth, in his annual report for 1907, which has just been issued, states that on an estimated population of 73,000 the total number of deaths was 827, giving a death-rate of 11·32 per 1000. 1205 births were registered, corresponding to a rate of 16·52 per 1000.

uttered didactically; and (3) twaddle; whilst Dr. Mackenzie's own definition was "a statement of ignored trifles or things taken for granted." We can certainly acquit his platitudes of having any part in the dictionary's final alternative, and if we accept the other two definitions in this special connexion, truth, no less than courtesy, demands the deletion of their contemptuous adjectives. Combining, then, our modified authority with the meaning which Dr. Mackenzie himself gives to a platitude, we may define it as "a statement which is so true as to be obvious, dealing with things so commonplace as to be taken for granted and which have consequently come to be ignored as trifles." We submit that this meaning puts a different complexion upon the despised platitude, and even though we allow our dictionary to add that it is "uttered didactically," may not such formal delivery invest its lesson with a force lacking in casual utterance? We are prepared to justify our defence of platitudes by quoting the three on which Dr. Mackenzie based the paper in question: "Carefully observe your patient and understand what you see." "Treat the patient and not the disease." "Observe what becomes of your patients." How often has young Laertes, M.B., freshly "capped and doctored and a'," listened to such platitudinous counsels from the tedious lips of Dr. Polonius, his professional father! Oh yes, he's heard all that a hundred times and only wants to be spurring on his way. And yet, if he ponder upon this trilogy of truisms (of which, by the way, the third deserves more attention than it generally receives), he may fuse them into a golden rule for the practice of medicine, a very compendium of its science and art. It is, as Poe insisted, the name writ largest on the map which we fail to find, the obvious which escapes our attention, and it is well to be now and again formally reminded of the importance of the commonplace principles upon which experience shows we may best conduct the business of our lives. And a platitude has this great claim to respect, that granted it embraces a truism, *a fortiori* it contains a truth, and in the practice of medicine the establishment of an unassailable fact raises a new rock of safety out of a shifting quicksand. The man who can find nothing but tedium in the contemplation of such platitudes as we have quoted, if asked his candid opinion of Newton's statement of the laws of motion, would not improbably confess that to his intelligence they appeared a somewhat pedantic expression of obvious natural phenomena, in fact, mere dynamical platitudes. It would never occur to this superior person that had the philosopher not embodied his observations in convenient formulæ the knowledge of these phenomena would not have been his own birthright. And so it is with the platitude, for which, in place of the dictionary's scornful utterance, we now venture the more respectful and handier definition of "crystallised experience."

URBAN MORTALITY IN IRELAND.

THE recently published yearly summary of the weekly returns issued by the Registrar-General for Ireland during last year records a rate of urban mortality in that part of the United Kingdom in marked excess of the rate that prevailed during the same period in the principal urban population of England and Wales. In the 76 large English towns, each having an estimated population exceeding 50,000, the mean rate of mortality during last year did not exceed 15·4 per 1000, while in London, with a population little short of 5,000,000, the unprecedentedly low death-rate of 14·6 per 1000 prevailed. The return referred to contains statistics relating to 22 town districts of Ireland, with an aggregate estimated population of little more than 1,000,000; and the population of the individual town districts ranged from 300,850 in Dublin city and 370,163 in Belfast, to 7909 in Queenstown and 7588 in Armagh. Indeed the population of but three of the Irish towns exceeded 50,000, while in each of 16 of the 22 town districts the population was considerably below 20,000. Notwithstanding, however, the inclusion of so many small towns in the Irish list the mean rate of mortality in the 22 town districts during last year was equal to 21·1 per 1000, exceeding the rate in the 76 far larger English towns by no less than 5·7 per 1000; thus the rate of mortality in the Irish urban population exceeded that in the principal urban population of England and Wales by 37 per cent. The contrast between the London and Dublin death-rates was still more startling. The recorded rate of mortality in the Administrative County of London during last year did not exceed, as is stated above, 14·6 per 1000; whereas in the Dublin registration area the death-rate was equal to 24·2, thus exceeding the London rate by 9·6 per 1000, and by no less than 66 per cent. Moreover, this excessive death-rate in Dublin was 1·1 per 1000 below the average rate during the ten preceding years. It is also worthy of note that the death-rate last year was equal to 21·3 per 1000 in Belfast, and that among the smaller Irish towns it exceeded 20 per 1000 in Cork, Galway, Kilkenny, Newtownards, and Waterford. These high rates of mortality in the Irish towns can only reflect the defective health condition of the urban population which calls for careful investigation. It is only possible here to note one or two facts disclosed by this summary of the Irish weekly returns. In the first place, it is clear that the excessive rate of mortality in the Irish towns is not due to exceptional fatality of epidemic disease, as the rate of mortality during last year from the seven principal epidemic diseases was identically the same—namely, 1·6 per 1000, both in the 76 English towns and in the 22 Irish town districts. It is true that the rate of infant mortality, which did not exceed 127 per 1000 births during last year in the English towns, was equal to 135 per 1000 in the Irish towns; this excess of infant mortality, however, accounts for but a small proportion of the excess in the crude death-rate in the urban population of Ireland. As the birth-rate last year in the Irish towns was equal to 28·4 per 1000, against 27·0 in the English towns, it is improbable that the excess of mortality in the former is due to any very exceptional age constitution of the population, but it may be pointed out that while the proportion of deaths of persons aged upwards of 60 years to total deaths did not exceed 26·5 per cent. in the Irish towns, it was equal to 29·2 per cent. in the large English towns. These figures appear to suggest that the main excess of mortality in the Irish towns occurs among adults aged between 20 and 60 years. The true explanation, however, of this excessive mortality is not disclosed by the Irish Annual Summary under notice, and could only be ascertained by a full and careful analysis of more-detailed statistics of the mortality in this Irish urban population, at various groups of ages and with due regard to its sex and age constitution.

THE EXISTENCE OF FORMS OF THE TUBERCLE BACILLUS WHICH ARE NOT ACID-FAST.

THE existence of forms of the tubercle bacillus which become decolourised in the course of the ordinary Ziehl-Nielsen method of staining is affirmed by Dr. Hans Much of Hamburg, in an interesting paper published in the *Berliner Klinische Wochenschrift* of April 6th. He has found that on making post-mortem examinations of cattle infected with tubercle bacilli of known origin and of ordinary characters, and presenting typical nodules in the lungs, the most careful examination may in certain cases fail to reveal ordinary acid-fast tubercle bacilli, in spite of the fact that inoculation experiments may demonstrate the tuberculous nature of the lesions and that from some of the cases tubercle bacilli may be obtained by culture. Similar results may be observed with

Art and Insanity.

From the day when Moreau of Tours gave a new form to the trite aphorisms of our ancestors and affirmed in set scientific terms that genius was a neurosis, distinction in art or letters has been a recognised title to the attention of the pathologist. The intellectual and moral aberrations of men of genius have been the theme of many volumes, most of which appear to have been compiled from the evidence of that notoriously disillusioned person to whom no man is a hero. Sometimes, too, it has been possible to supplement the testimony of the valet with information gleaned from the great man's tailor or his hatter and so to ascertain, for instance, whether the laurel wreath of fame rests more often on an oxycephalic or on a scaphycephalic cranium. The result of these investigations, according to the enthusiasts who have pursued them, has been to establish quite conclusively the kinship of great wit not only to madness but also, and in even nearer degree, to epilepsy and to crime, and to prove that originality of thought, if not perhaps quite as dangerous socially, is fully as morbid and as indicative of "degeneracy" as any form of delinquency known to the law. This doctrine has been found very useful when it has been desired to attach the stigma of unhealthiness to literary or artistic work which shows any tendency to depart from traditional models, and it is with this application of it to modern writers and artists that we are most familiar. So useful, indeed, has it proved in this way to the advocates of conservative ideas in art that they have for the most part confined themselves to this use of it and have never imperilled their faith in the general soundness of their theory by pursuing the complementary line of inquiry and seeking for evidences of original talent in the art of the insane.

It may therefore be worth while commending to their notice and to the notice of all who are curious in these matters a small volume recently published by Dr. Marcel Réja under the title of "L'Art chez les Fous."[1] In this very interesting contribution to a comparatively neglected subject Dr. Réja is mainly concerned with the efforts of the insane in literature and in design, while he touches only briefly on sculpture and makes no reference at all to music. This latter omission, we may note in passing, is somewhat significant, for it is due to the fact that it is extremely rare for the insane to seek in music an outlet for their morbid artistic activity—a fact which must be rather embarrassing for those who would have us believe that the great development of music in modern times is one of the morbid symptoms in contemporary art. Whatever be the explanation, it is certainly the case that the art of the lunatic asylum is practically confined to pictorial and literary expressions, being characterised in both by peculiarities of somewhat similar import. Of these peculiarities the most constant and distinctive is, curiously enough, not a spirit of licence and innovation but, on the contrary, a spirit of excessive traditionalism. In the pictorial art of the insane, for instance, the most characteristic feature is the resemblance to archaic art, and this, it may be remarked, is seen both in the work of lunatics who have received a technical training before the onset of their mental disease and in the work of insane amateurs. The mad painter, far from introducing startling innovations in technique or conception, is much more inclined to revert to primitive formulas. So far does this tendency go that the designs of the insane often reproduce the naive devices of the early masters, so that, for instance, as in primitive frescoes, the size of the personage will be made to correspond not to their place in the perspective but to the importance of their rôle in the dramatic action, or, again, several successive phases of the same action will be represented in the same picture. When not distinguished by a reversive tendency of this sort the works of insane painters, unless quite incoherent, are, as a rule, without any special characteristics at all; certainly they hardly ever reveal, even in the most rudimentary degree, any straining towards new horizons. And we find just the same lack of originality when we examine the literature of the asylum; and here, of course, we have more abundant material to deal with, literature being notoriously the favourite direction for the artistic energies of the lunatic. The most striking feature of insane literature, and one doubtless which may also be regarded as of reversive significance, is the predominance of poetry; relatively few lunatics, and, as a rule, those only whose mental integrity is but slightly impaired, make any attempt to produce work of literary pretensions in prose. This preference for the metrical form appears to be due in great part to what may be termed an orthopædic influence of verse on the invalid brain; verse supplies, as it were, a channel into which the incoherent stream of words and images can be poured, so that in the automatic activity of the disordered mind metre and rhyme act as substitutes for the processes of rational association. In the examples quoted by Dr. Réja the rhymed alexandrine is the most usual form of metre; in part, no doubt, the literary traditions of France might be expected to create a preference for this type of versification, but it is probable that the chief reason for the general use of this or of some other variety of rhymed couplet is to be found in the obvious advantages of such a simple metre as a means of giving rhythm to the insane logorrhœa, for the same pedestrian sort of verse is specially affected by asylum poets in other countries. If there is no novelty of technique to be discovered in the poetry of the mad-house, it is equally hard to discern in it any originality of conception; the characteristic of its matter is rather, indeed, a tendency to a dreary didacticism reminiscent of the late Mr. Martin Tupper in his most platitudinous moments. Even in the very rare instances where verse of real distinction is written under the influence of insanity, this influence is shown chiefly in a too faithful observance of traditional formulas, which gives it at its best the appearance of a passable imitation of some accepted master of style.

The conclusion of the whole matter is, then, that, alike in literature and in painting, conventionality and traditionalism appear to be the distinguishing features of the work of the insane; so that if we are to deduce from the characteristics of that work our criterion of what is morbid in art we shall be more likely to discover

[1] L'Art chez les Fous: le Dessin, la Prose, la Poésie. Par Marcel Réja. Paris: Société du Mercure de France. 1908. Pp. 235. Price 3fr. 50c.

Mr. Arthur Edmunds showed at a meeting of the Society for the Study of Disease in Children [3] an English baby with similar pigmentation in the sacro-iliac region. The occurrence of the so-called Mongolian pigmentation in European infants may therefore be accepted as a fact, but the condition would appear to be one of great rarity.

AN "ACADEMIC PROLETARIAT."

"THE phrase" (writes an Italian correspondent) "is Guido Baccelli's who, when Minister of Public Instruction, coined it in order to give currency to an impression, borne in upon himself and his predecessors in office, as to the evil wrought by Italy's plethora of universities which turn out annually many hundreds of graduates in law, in medicine, and in engineering, of whom scarcely one half can expect to gain a livelihood by their nominal profession. What becomes of this great army of the educated unemployed? Disdaining to go into commercial or industrial pursuits, for which indeed they have scarcely more aptitude than training, they reinforce the already swollen ranks of journalism mainly political or of parliamentary 'agitation' mainly demagogic. Hangers-on of this or that political group, they court the patronage of its chief by services on the platform or the press, contributing to journals which crop up like mushrooms, often as deciduous as they are unwholesome, or strutting their little hour on public platforms and diffusing the malady, of which they are alternately the cause and the effect, known to continental alienists as 'mania contionabunda.' All this was put before parliament in Italy some nine or ten years ago by Dr. Baccelli in the memorable speech in which he advocated the reduction of Italy's multitude of seats of learning to a minimum of four which, duly endowed and equipped, would be beyond the temptation of competing with each other in the matter of matriculation, curriculum, and graduation, and by making their degrees attainable only by earnest and competent aspirants would bring down the total of graduates to a number corresponding to public wants and so cut at the roots of the upas tree—'the academic proletariat' aforesaid. Unfortunately, the administration in which Baccelli was charged with the portfolio of Public Instruction collapsed before his Bill for University Reform could pass through its preliminary stages, and so the mischief wrought by the plethora of 'seats of learning' remains as active as ever—to the prejudice alike of professional efficiency and of public well-being. In fact, the University curriculum would seem often to be accepted by the undergraduate less as a preparation for the legal or the medical calling than for the career of the 'publicist,' if we may judge from the proneness of the student to intervene in the politics of the hour, domestic or international. Messages of sympathy, voted by undergraduates 'in council assembled' (which is often but a turbulent meeting in the quadrangle), are despatched to this or that 'cause,' native or foreign, which happens to be in conflict with the central authority; sides are taken with a fervour and a vehemence redolent of the parliamentary arena rather than of the 'Groves of Academe'; and many a youth who might have made a respectable citizen as practitioner in law or medicine is seduced by the success of his harangue and the triumph of his 'side' to pose ere long as a little Gracchus hungry for 'place,' or (let us say) as a 'Gracchulus esuriens' in the parliamentary lobbies. Aping the methods of the industrial proletariat, as these are dictated by the professional agitator, the undergraduate here goes out on 'strike' and just the other day we had all over Italy outbreaks of the 'sciopero accademico' on the part of students who wanted their own way in the matter of examinations or who bore a grudge against this or that professor. Interrupting not merely their own studies but those of their class-fellows from whom they exact 'solidarity' or action in common, they convert the curriculum of the year into little more than a farce, so that failing (naturally enough) to meet the examination test in their own university they are fain to court that of another more accommodating. All this, as seen and deplored by successive Ministers of Public Instruction but never put so powerfully in evidence as by Italy's prominent clinician and senator Guido Baccelli, calls loudly for remedial legislation, beginning with the suppression of at least three-fourths of the existing universities and the absorption of the resources of these into the four, as proposed by Baccelli, which would encourage real learning and exclude all but the duly qualified from the professions. True, the reform indicated is fraught with difficulties. Just as in the matter of the civil list the King is periodically importuned in Parliament to suppress the many palaces inherited from the deposed dukes, grand dukes, and tiny monarchs who disappeared with Italian unity, but has always to declare his inability to do so from the local protests raised by the communities in which the said palaces are cherished as an heirloom and an asset, so in the case of the universities which, equally with the palaces, are retained long after the duchy or the kingdom to which they belonged has ceased to exist, the reformer who proposes to extinguish them so as to concentrate their lights and to feed a larger and more illuminating flame is met by an outcry from the 'seat of learning' and its neighbourhood which forces him to desist, under a pressure aided and abetted by Parliamentarians who, radical in other questions, become conservatives indeed when their local interests are threatened. And yet something must be done, and that right early and right thoroughly, if Italy is to rise to the height from which she has declined since the Renaissance and make her universities the true 'Almae Matres' or 'nursing mothers' which they once were, not only to herself but to the outlying world. Then, but not till then, shall we witness the disappearance of 'academic strikes' and 'quadrangular duels' between professoriate and *Burschenschaft* and with it the deflection of undergraduate energies into their normal and fertilising channels—to the revival of Italy's fair fame in the sphere of research and practice and to the extirpation of that malignant fungus now poisoning her public life—the Academic Proletariat."

VACCINIA AND VARIOLA.[1]

THE Association of Public Vaccinators of England and Wales has done well to publish Dr. De Korte's paper read at its annual meeting last October. The paper constitutes a most useful addition to the easily accessible literature on the subject. It differs from most writings in defence of vaccination in respect that it touches only slightly on the statistical evidence and confines itself almost wholly to a historical and scientific study of the vaccinal process and to the nature of the immunity conferred. The statistical evidence that vaccination prevents small-pox is so overwhelmingly strong and has been so frequently set forth that there was no need for its repetition, but the bacteriology of vaccinia and variola has been seldom dealt with excepting in larger works. Dr. De Korte discusses the principle of Jennerian vaccination and refers to the experiments of Simpson and King and others as to the relationship of cow-pox to small-pox. He discusses also the cause of ulceration in Jenner's day and the side-chain theory and alexocyte theories of immunity, the histological changes in variola and vaccinia, umbilication and method to one-quarter of the original number. In default of effecting any reduction in the number of rats present in a place the access of rats to man must be minimised by the latter vacating places where rats, and especially plague-sick rats, have been found. Evacuation should take place *immediately* after the rats have died. This measure, as it is pointed out, is efficient for preventing the development of plague amongst man, provided it is adopted early enough—that is, before or immediately after rats have been found dead in a house. But it is dangerous when it encourages those who have been living in the midst of infected surroundings to seek refuge in healthy towns and villages in order to avoid the discomfort of a camp life.

[1] Vaccination Scientifically Considered, by W. E. De Korte, M.B. Lond. Published by the Association of Public Vaccinators of England and Wales. Price 6d.

Lastly, and if we could only insure its universal application, the method of inoculation which has been brought to such a pitch of perfection by Mr. HAFFKINE is the surest means of prevention. Everywhere throughout India the results obtained, contrasted with control experiments, show this, and no greater benefactor to the Indian people has ever visited that country than this distinguished *savant;* even after five years some trace of protection remains. Testimony to its good effects is afforded not only by the communities inoculated but also by the police, the railway companies, and the mill-owners amongst other bodies. Captain LISTON concludes his admirable advice by showing that no single anti-plague measure should be adopted to the exclusion of others; each has its advantages. Where danger is imminent inoculation can best be practised; where it is wished to anticipate the possible epidemic in any village destruction of rats is most advantageously carried out. Evacuation is also a useful adjunct to inoculation. Evacuation and inoculation promptly carried out will stop any epidemic. Professor SIMPSON narrates a striking case occurring in Cape Town where plague was becoming serious amongst the Kaffirs. It having been decided to remove them from their insanitary dwellings some 7000 to 8000 were so removed and all were inoculated. The epidemic at once ceased. In conclusion, it may be mentioned that Professor SIMPSON strongly recommends the disinfection of a plague-stricken domicile by sulphurous acid gas by means of the Clayton method. This will destroy not only the plague germ but also rats, fleas, bugs, and other agents capable of conveying the infection, and, moreover, does away with the irritating procedure of removing all the different effects and chattels of the natives elsewhere for disinfection, as everything is thus dealt with *in situ*.

Annotations.

"Ne quid nimis."

THE NEW CABINET AND THE PUBLIC HEALTH.

WE have on several occasions recently discussed in our columns the status of the Local Government Board and we have pointed out the disabilities which attach to any offices other than those of Secretaries of State by virtue of the promotions which take place from time to time in any given Cabinet and which have often the effect of depriving some important Government department of the services of its president just as such president has had time to learn the work of the department. Probably no other department has suffered more from these Cabinet promotions in the past than the Local Government Board, and in a recent leading article in our columns we protested against the removal of Mr. Burns from that office at a time when he had introduced important public health measures into Parliament and when several others were likely to follow shortly. At the same time we did not for a moment suggest that Mr. Burns should forego any promotion to which his services have justly entitled him, and we suggested that his promotion should take the shape of an exaltation in status of the office which he now holds. We are therefore very pleased to see that events have justified our prophecy and that Mr. Burns is to remain at the Local Government Board to pilot through the House his important Housing Bill as also we trust, amongst others, measures relative to the better control of milk and meat and to the creation of river boards by means of which public health authorities may be better able to deal with the pollution of rivers, the purity of water-supplies, and, last but not least, to secure the wholesomeness of the numerous forms of shell-fish which are consumed in such large quantities and often with such disastrous results to the consumers. The continued reign of Mr. Burns at the Local Government Board will afford him opportunities of redeeming his pledges to deputations in these respects, and for this reason we cordially congratulate him upon his re-appointment as also upon the fact that he has been given as a Parliamentary Secretary Mr. C. F. G. Masterman who takes great interest in natural science and in all schemes for the moral advancement of the people. We have yet to learn what are the precise proposals which the Prime Minister will present to the re-assembled Parliament relative to the status of the Local Government Board and the Board of Trade. We see, for instance, suggestions that the pay of each of these Ministers is to be raised to Secretary of State level but that they are not to enjoy the accompanying rank. We trust that no such invidious distinction will be made, as it seems clear from the recent debate which took place in the House of Commons on the subject that Mr. Asquith fully recognised the absurdity of the existing disparities in so far as the Local Government Board and the Board of Trade were concerned and that both sides of the House were in complete harmony on the subject. A department such as the Local Government Board, which deals with public health, pauperism, local expenditure, and a host of other matters affecting intimately the daily life of the whole population, should enjoy a status second to no other department of the State and we trust that full justice will at last be meted out to it.

A PLEA FOR THE PLATITUDE.

THE Glasgow Southern Medical Society has for its badge a clamant cockerel beneath the defiant motto "While I live I'll crow." We are happy to say that the society has carried out its purpose for 64 years already and has recently shown by a lusty note raised from the presidential chair that it is still animated by the spirit of its founders. The occasion to which we allude was an address delivered by Dr. James Mackenzie of Burnley under the title "Some Platitudes and the X Disease," in which he upheld with convincing vigour the claims upon the gratitude of Medicine which have been earned by the great body of her general practitioners, and the purpose of his address was to set forth the way in which it seemed to him the continuance of those claims might be assured. He brought forward his advice under three headings, to which he made deprecating allusion as "Platitudes of Medicine." A certain standard dictionary gives us three meanings for platitude: (1) a written or spoken statement that is flat, dull, or commonplace; (2) an insipid truism, especially when abdomen, but especially on the right side. On August 1st the pain increased and on the 2nd he was seen by Dr. Duvergey. The pulse was 120, the temperature was 103·2°, and there were muscular rigidity particularly in the right iliac region and tenderness greatest at McBurney's point, where a hard mass was beginning to appear. The condition became worse and on the 7th vomiting of the same character as in the preceding case occurred. Operation revealed a fœtid retro-cæcal abscess which was drained. Recovery ensued. These cases show that appendicitis may be accompanied by the vomiting of liquid containing blood in such small quantity that on superficial examination it may be unnoticed, particularly if the microscope is not used. Dr. Duvergey ascribes the hæmorrhage to ulceration of the gastric mucous membrane from the interference with its nutrition produced by small emboli brought to it from a focus of infection. Hæmatemesis in appendicitis denotes a more or less profound infection of the body and increases the gravity of the prognosis but slight hæmatemesis is not of such serious significance as severe hæmatemesis. Seven out of nine cases of the latter reported by Professor Dieulafoy proved fatal. On the other hand, in the first case of slight hæmatemesis related above the course was benign.

DIPHTHERIA IN ELEMENTARY SCHOOLS.

AN interesting paper on this subject was read at the recent meeting of the Royal Sanitary Institute at Hull by Dr. J. Wright Mason, medical officer of health of the City and Port of Kingston-upon-Hull. After a reference to some points in the bacteriology of the disease Dr. Mason drew attention to the observations of Dr. D. S. Davies who noted that at one time in the same town the type of the pathogenic bacillus may be distinctly different from that found at another time, and that the differences of type are accompanied by different characteristics of the disease both as to fatality and infectivity. This same variation occurs with some of the other infectious diseases and is difficult to explain but is important to remember in estimating the value of new therapeutic measures. Dr. Mason also mentioned that "common cold and sore-throat" are often the precursor of outbreaks of diphtheria in schools, and consequently rightly urged that when a case of diphtheria is recognised all proper measures for isolation and quarantine should be at once adopted. Recent bacteriological investigation has confirmed the suspicion long entertained that children may act as "carriers" of infection without themselves presenting symptoms of diphtheria; consequently Dr. Mason emphasises the importance that when a child attending school is found to be affected with the disease a medical inspection should follow of the family and other children of the class or school. Swabs should be taken from their throats for bacteriological examination and in cases where diphtheria bacilli are shown to be present such children should be excluded from school and should not be allowed to return until they have been declared by bacteriological examination to be free from infection. Dr. Mason further insisted that during epidemic periods there should be frequent medical inspection of the schools and that infected "contacts" and those who have been exposed to infection should be injected with a prophylactic dose of antitoxin. The protection afforded by such treatment lasts about three weeks and if the throat is not clean at the expiration of that time Dr. Mason advises that the dose should be repeated. He also reminded his hearers that another point should not be overlooked with regard to diphtheria—namely, that discharges from mucous membranes are exceedingly prone to recur, and that after a patient has been declared to be convalescent the discharge may recur on exposure of the individual and become a possible source of infection. The various points to which attention were drawn by Dr. Mason are generally known and accepted, but they cannot be too frequently brought before the notice of the sanitary authorities, so that every precaution available to modern science can be utilised when necessary.

A CASE OF HODGKIN'S DISEASE WITH GENERAL EOSINOPHILIA.

A CASE of some interest is described by Dr. O. H. Perry Pepper in the *Bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital*, No. 4, December, 1907. The patient was a woman, 50 years of age, an Austrian by birth, and was admitted into the Pennsylvania Hospital on June 22nd, 1907, under the care of Dr. Morris J. Lewis. In February, 1907, she began to lose appetite and to suffer from vomiting and abdominal pain. She lost flesh and her abdomen became distended. The superficial lymphatic glands were found to be enlarged, including the epitrochlear, axillary, supraclavicular, cervical and parotid glands, some of them being as large as pigeon's eggs. The spleen extended downwards and forwards three inches below the costal margin in the mid-clavicular line. It was smooth and was not tender on palpation. The liver was found to extend from the fourth interspace to two and one-eighth inches below the costal margin in the parasternal line. There was slight pre-tibial œdema and a papular eruption was found on the body due to pediculosis. During the patient's stay in hospital she suffered from an intermittent febrile temperature reaching up to 102° F. For some days after admission she appeared to grow worse, the glands and spleen enlarged, and a deep-seated mass of indefinite outline was felt in the left side of the abdomen. Shortly afterwards she improved but left the hospital against advice on July 22nd. During her stay in the hospital the blood was examined four times. On admission there were 3,960,000 erythrocytes and 21,500 leucocytes per cubic millimetre. A differential count showed 77·6 per cent. polymorphonuclears, 4 per cent. lymphocytes, 4·8 per cent. large mononuclears, and 11·6 eosinophiles, i.e., an absolute count of 2494 eosinophiles per cubic millimetre. The percentage of hæmoglobin was 59. On a subsequent count the number was 4608 eosinophiles per cubic millimetre, a percentage of 16 of the total leucocytes. A further count made shortly before the patient left the hospital gave 3,800,000 erythrocytes and 16,160 leucocytes, the differential count being 46 per cent. polymorphonuclears, 40 per cent. lymphocytes, and 8·8 per cent. eosinophiles. The fæces were searched for ova of parasites but none were found. The sputum was examined for tubercle bacilli with negative result and no cause could be found for the eosinophilia. Another noticeable feature in the blood was the increasing numbers of lymphocytes which is said to be a feature of Hodgkin's disease. The diagnosis was confirmed by removal of a gland from the axilla for microscopical examination which was carried out by Dr. Longcope who obtained results typical of the cellular form of Hodgkin's disease. The normal structure of the gland was lost; it was made up of a fairly delicate reticular meshwork through which ran great numbers of small blood-vessels. The meshwork contained cells of many different types mixed together without definite arrangement. There were small mononuclear cells, epithelioid cells many of which showed karyokinetic figures; a few mononuclear giant cells and enormous numbers of eosinophilic cells, most of them being multinuclear. A few plasma cells were also seen. Goldmann and Kanter so long ago as 1894 described the presence of eosinophiles in the lymph glands in Hodgkin's disease and their observations have been abundantly confirmed, but it is only recently that general eosinophilia has been observed in that disease. Dr. Pepper after examining the reports of 19 other cases the so-called "cold abscesses" resulting from the tuberculous process in the human subject. Dr. Much, by using Gram's method as well as the Ziehl-Nielsen, found that there were two forms of the tubercle bacillus which were not acid-fast—one a rod-shaped form which is partly granular and the other a granular form consisting of granules lying singly or clustered into irregular groups. To demonstrate these forms he employs Gram's method, leaving the preparations in the gentian-violet solution for 48 hours before decolourisation. If sections of tuberculous tissues from which no ordinary bacilli were obtained were stained in this manner they sometimes showed large numbers of fine rods in some of the tubercles, often lying in the cells, while in other cases only fine granules lying partly in rows, partly irregularly, were to be seen. Small pieces of fresh lung tissue from such a case (free from other organisms) were incubated for varying periods in serum tubes placed in an incubator at 37° C. At first only granules and rods staining by Gram's method were obtained, but after incubating for six days bacilli staining by Ziehl-Nielsen's method were also recognisable. The granules were not artefacts due to precipitated stain, since they were only found in the tubercles, and no irregular precipitation was observed elsewhere. Other experiments are described showing that under various conditions the ordinary form can be converted into a granular form and yet retain its virulence. Dr. Much, in a paper on the same subject published in the *Beiträge zur Klinik der Tuberculose*, Band VIII., Heft 1, p. 85, gives his methods and his results in more detail. He suggests that the Ziehl-Nielsen staining depends upon some other constituent of the bacillus than that upon which the Gram method rests. In a paper in the same number of that journal by Dr. N. A. Michaelides similar conclusions are arrived at. He also states that there is a form of the tubercle bacillus which does not stain either with Ziehl-Nielsen or with Gram, but which can be demonstrated by the Loeffler-Giemsa method of staining, details of which he gives. These observations are of considerable interest and may prove to be of practical importance in diagnosis.

THE PERADVENTURES OF AN INDIAN LIFE-TABLE.

Sir J. Athelstane Baines, C.S.I., on April 14th read before the Royal Statistical Society a paper with the above title, which was the evident product of much careful study. The ingenious generalisations by which he sought to reduce to order the erratic returns which are alone available for the construction of Indian life-tables could receive proper appreciation from those engaged in actuarial work alone, but the paper contained much information of value to all who are interested in India's welfare. The "peradventures" of which he treated are of double origin, the untrustworthiness of all age returns made by an ignorant people to whom a registration system is still strange, and the incidence of famine which, by the interruptions of regular age-sequence caused by a lowered birth-rate, leaves its mark on the life returns of the whole generation which follows its devastations. In the great drought of 1896–97, for instance, an area of 276,000 square miles, supporting 52,000,000 of people, was famine-stricken, and the same fate befell 489,000 square miles and 58,000,000 of people in 1899–1900. The Census Commissioner estimated the actual loss of life on these occasions at more than 5,000,000. On the other hand, a bumper harvest is sure to be followed by an abnormally high birth-rate, so that the statistical record of the population is from famine alone subject to double disturbing influences. We are surprised that Sir Athelstane Baines made no reference to plague which, taking as it does its toll of millions of lives, must surely affect the birth-rate of its centres of activity in a ratio too inconstant to be predetermined. In dealing with incorrect returns of age, and setting aside the fallacies caused by wilful misrepresentation, the lecturer pointed out a source of glaring error (which occurs in the census returns of other illiterate nations), namely, the overwhelming preponderance of persons stating their ages in multiples of five. Thus, 54 per cent. of people returned their ages as one of the first 15 multiples of five, whilst there were only 46 per cent. who chose the remaining 56 figures open to them as the measure of their years; in every decade the 5 and 10 receive an undue number of claims. The only exception is the year 12, which was claimed for a disproportionately large number of children, 12 being nearly universally regarded as a lucky number; on the other hand, the nines in each decade are markedly avoided from superstitious reasons. A very general overstatement of age in advanced life was found and Sir Athelstane Baines went so far as to say that unless the age could be approximately fixed by some impressive event a margin of 25 or even 30 years could be safely allowed in dealing with the alleged centenarians of India. Another very difficult factor to reckon with is the unduly large proportion of young children in the community, resulting from almost universal marriage amongst adults. The paper described a highly technical method of smoothing out the many rough places in the preparation of Indian life-tables, a work in which Sir Athelstane Baines attributed an honourable share to Mr. S. F. Hardy. This paper is sufficient proof of his own fruitful labour in the same field. Amongst the many formidable tables which illustrated his remarks was one showing the unadjusted return of annual periods concerning which the lecturer quoted the phrase of a Calcutta biographer which has become classical in India, that it "exposes its *cui bono* in all its hideous nudity"!

THE CONGENITAL PIGMENTATION OF MONGOLIANS.

THE subject of the congenital pigment spots or birth marks in Mongolians, to which Mr. Edward P. Leavy has drawn attention in another column, has been studied and discussed by Japanese physicians and accoucheurs for over 150 years. Almost all Japanese infants present at, or soon after, birth one or more blue-looking spots in the lumbo-sacro-gluteal region. The centre is of a bluish-black colour and the peripheral area is lighter in appearance. The spots vary in size from that of a pea to a hand's breadth and may sometimes be found scattered over the back and on the extensor surface of the extremities. They usually disappear during the first five years of life but may persist until puberty, or more exceptionally throughout life. A typical example of the condition was shown at the Clinical Society of London in 1905,[1] the subject being a Japanese baby aged ten months. Dr. Adachi of Japan has fully discussed the question of this pigmentation in man and apes in a paper published in 1903.[2] Monkeys possess pigment cells scattered generally and superficially over all parts of the body. The coloured races, for the Mongols are not alone in this peculiar pigmentation, show larger pigment cells lying in the corium and distributed in the special areas referred to above. In the white races these pigment spots are microscopic in appearance and for the most part non-existent. Dr. Ashmead believes that the spots are evidence of a negroid parentage. The fact that they are present as a rule only during embryonic or early life would suggest that they now represent merely an earlier stage of evolution when the condition was more persistent and possibly served some function. It is of special interest to observe that some Japanese physicians have discovered this typical pigmentation amongst pure German infants, while in this country hand, is extremely desirous of getting these principles established before the hospital is moved and has convened a meeting of the medical practitioners of South London in the Town Hall, Peckham-road, on April 30th, at 4 P.M., when propositions embodying those principles will be moved after addresses have been delivered by several medical men. The points at issue open up fields too wide for discussion now; we shall return to them later.

---

[1] THE LANCET, Nov. 4th, 1905, p. 1331.

[2] Zeitschrift für Morphologie und Anthropologie, 1903, Band vi.

THE Department of Public Health of Queensland in a bulletin dated March 7th states that a case of plague occurred at Brisbane on March 3rd. The patient was a male, aged 17 years. He was employed at a warehouse in which plague-infected rats had previously been caught. As regards the Gold Coast, a telegram received at the Colonial Office on April 14th states that during the week ending April 11th there had been 2 deaths from plague at Accra and 1 at Dodowah. All other places had been free from plague. A further telegram received on April 20th states that for the week ending April 18th there were no fresh cases of plague either at Accra or elsewhere in the colony.

UP to date 109 papers have been announced to be read before the First International Congress of First Aid to be held, as announced, in Frankfort-on-the-Main on June 10th to 14th. 25 of these papers are on first-aid in towns and 17 on first-aid in mines and similar works. Papers have also been prepared on first-aid at sea, at fires, on the railway, on the land, on the mountains, and in sport, and on the improvement of non-medical assistants. An exhibition of motor ambulances, sick wagons, and ambulance apparatus will include several novelties.

THE unexpected death is announced from Vienna of Professor Leopold Schrötter, the well-known laryngologist.

SANITARY REFORM IN INDIA.

VI.[1]—THE PLAGUE PROBLEM (*concluded*).

Burma.

A VERY complete and exhaustive survey of the whole subject of plague has been given by Colonel W. G. King, I.M.S., in the report on the Sanitary Administration of Burma for the year 1906, and he deals with the matter in a manner which entitles him to the greatest credit. The whole of the plague rules under the Epidemic Diseases Act underwent a thorough revision, more especially as regards the giving power to local authorities to secure a system of surveillance in advance of plague. It was laid down that in no case should segregation be regarded as the prime rule to be enforced at the commencement of an epidemic unless there was reason to believe that the persons concerned were so untrustworthy as to be likely to leave the neighbourhood of an infected locality without giving information of the fact. Instead of segregation "exemption certificates" were issued, requiring attendance once daily for six days. This proved useful in practice. Ward headmen and block elders had assigned to them definite duties in aid of the civil authorities, so as to enable the system of surveillance to be enforced, whilst the general conduct of disinfection and the organisation necessary in respect to *personnel* and equipment were explained in an appendix to the official notification issued by the Government. But for the correct working of these rules of course a sufficient staff was necessary, and, unfortunately, Burma possessed no certificated sanitary inspectors. Hence to remedy this defect so-called temporary plague inspectors were trained. The Government likewise, owing to the increase of plague, placed at Colonel King's disposal Captain H. A. Williams, I.M.S., D.S.O., as special plague officer for the province, under whom the inspectors were trained and the methods of treating the disease were harmonised. Colonel King himself continued the personal inspection of plague-infected areas as far as possible. There was a total of 8637 deaths from the disease in 1906, or an increase of 4945 as compared with 1905, the death-rate advancing from 0·44 in 1905 to 1·02 in 1906.

Regarding the measures pursued, steam disinfection was substituted for the wet methods of disinfection hitherto employed, this method being more popular probably with the owners of clothing. The success of the Clayton apparatus in killing rats induced Colonel King to ask for sanction for the purchase of the necessary machines, by means of which it was found that if the holes are sought for and the exits are discovered and closed rats can be killed freely. Even when these holes cannot be found and closed the machine is most useful in ejecting rats in a feeble condition so that they can be killed by sticks, and also by tracing the fumes the rat runs can be followed, which, of course, when the rats are infected by plague is important. Colonel King rightly considers the method of dealing with rats by sulphurous fumes, irrespectively of the length of the burrows, very important. The fumes only require to be forced in quickly to displace the air and to overpower the rats. Liston has shown that 0·4 per cent. of the gas suffices to kill the fleas. The Civil Surgeon of Maymyo advises the "flaming" method of disinfection for plague suggested by Colonel King in 1899. The latter officer, however, hesitated to advise its general adoption in a country where wooden structures are the rule. With the most ordinary care, however, he considers it safe even when applied to wooden buildings.

Colonel King very wisely comments on the abandonment of "passporting," which had been legalised by the Government of Burma, consequent on the representations by the commercial communities that the method would trammel trade in the province. These representations are short-sighted. For the prevention of plague, early detection is of prime importance. Man is the great agent for the introduction of the disease; once introduced, rats will disseminate it, but the latter animals are not the sole prime agents involved. This is shown by the results of the investigation of the civil surgeons during 1906. Of 43 cases of plague, in 39 the introduction of the disease was traced to an infected person arriving from an infected area, the infection of rats being the disastrous sequel where sanitary measures were not sufficiently prompt or complete. At present the rules in vogue merely give increased power of controlling "contacts" so long as they are within the infected areas; on their departure, therefore, no system of observation is maintained. Some approach to the passport system has, however, been allowed in uninfected areas lying close to the infected, and this, combined with a surveillance system, has detected several importations and thus presumably has prevented indigenous plague.

Surveillance without the aid of the passport system was also successfully utilised in some instances. At Insein, for instance, Major Singh, I.M.S., caused evacuation of portions of the town inhabited by railway employees during the severe epidemic of the disease that was present early in 1906. The plague then ceased. Surveillance was then rigidly resorted to and before the end of the year 43 cases imported from Rangoon were detected and were promptly treated sanitarily, with the result that although within nine miles of the constantly infected Rangoon and in constant touch with it the place remained free from indigenous infection. Dr. Gaudoin, again, in Yamethin, by organising surveillance and by prompt sanitary action prevented an outbreak of indigenous plague, notwithstanding the infected condition of the neighbouring towns of Pyinmana and Pyawbwe.

Another method was consistently pursued—namely, rat destruction, which was carried out not only after the invasion by plague of a locality but also in advance of any such occurrence. During the year 4,366,867 rats were killed in the province at a cost of Rs. 253,260, or 11·1 pies per rat. But it is found that the problem of killing rats at a cost that will not prohibit other necessary preventive measures has not yet been solved. The reports of the Deputy Commissioner show that he had no hope of any permanent diminution of their number, notwithstanding all the strenuous efforts undertaken to destroy these animals. The Government of Burma, however, was prepared during 1907 to undertake experimentally microbic efforts in this direction. In the meantime various poisons, rat-traps, and asphyxiators have been employed. So long as the burden of taking life rests repair, and the etiological agent of small-pox and vaccinia. He brings well up to date the present knowledge on the subject, referring to the bipolar bacillus of Klein and Copeman, the cytoryctes variolæ of Guarnieri, and the sporidium vaccinale of Funk. Dr. De Korte himself has done some original work on the same lines and is well qualified to set forth the present position of investigation. His brochure will be found very useful by students of the subject.

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Feb. 22nd (p. 582) and 29th (p. 661), March 14th (p. 806) and 21st (p. 883), and April 11th (p. 1101), 1908, respectively.

EARLY SITTING UP AND RISING AFTER LAPAROTOMY.

IN the *Albany Medical Annals* for February Dr. George Chandler has advocated the sitting up and rising after laparotomy at a much earlier time than is customary. He adopted this treatment independently, but subsequently found that it had been followed previously by Dr. Herman Boldt of New York and that Dr. Emil Ries of Chicago appeared to have been its pioneer. The following case suggested the treatment to Dr. Chandler. He operated on a man for acute appendicitis in the country under most unfavourable conditions. On going to see the patient next day he was astonished to find him standing at the window shaving himself. He refused to go to bed, went about fully clothed as if nothing had happened, and, to Dr. Chandler's surprise, made an excellent recovery. When Dr. Chandler was house surgeon at St. Vincent's Hospital, New York, 12 years previously patients were kept in bed for four weeks after laparotomy by Lusk, Bryant, and others. During the five years he was connected with the hospital this period dwindled down to two weeks. Then Morris adopted ten days and others even a shorter time. About two and a half years ago Dr. Chandler in a few selected cases had his patients propped up on the second day and sitting on a chair on the fifth day with good results. He now adopts the following method. All the patients, no matter what the lesion or how weak they are, recover from the ether in the sitting posture, in which they are supported by a bed-rest. The result is that they have very little nausea. He keeps them in this position for 12 hours and then allows them to lie down and to assume any position that is comfortable. After they have rested they are encouraged to sit up again with the bed-rest for almost the whole of the next 24 hours. On the third day, if they are strong, and on the fourth, in any case, they are sitting on a chair. Some walk on the fourth day; all do so on the fifth. Subsequently they walk about or sit with their clothes on during the day until they leave the hospital, which they usually do from the tenth to the fourteenth day, well and strong. Dr. Chandler's experience of this method includes about 200 laparotomies and that of other American surgeons over 800. The results have been most gratifying. After closing the abdominal wound Dr. Chandler applies a single broad bandage of zinc oxide plaster extending from just above the pubes to the umbilicus. As regards internal treatment, the patients are given sips of water or bits of ice after the first 12 hours. If there is little flatulence and no gastric or intestinal symptoms are present they are allowed on the second day sterile water, orange juice, and weak coffee or tea, but no milk. The bowels are moved on the third day by divided doses of calomel, followed by a saline. Stimulants are never given, however weak the patients, but if necessary during the first two days they are made comfortable with hypodermic injections of morphine. If the patient's condition is grave, salines are given by the rectum or subcutaneously and the stomach is washed out. After the bowels have acted on the third day a light diet is given and by the fifth day a full diet. If there is acute general peritonitis a large fenestrated rubber tube is inserted deeply into the pelvis through a median incision. A wick of gauze is passed through this and extends from the bottom of the cavity to the gauze outside the abdomen. The patient is placed in a perfectly upright position in the bed, not merely elevating the head and shoulders but also the pelvis. Drainage of the abdomen will take place by gravitation alone during the first 12 or 24 hours, never longer, therefore the importance of posture at the beginning is great. By securing the most upright position possible infectious material will gravitate into the pelvis, where it can be reached later through the rectum or vagina. After the patient is properly placed in bed saline solution is given by the rectum according to Murphy's method. The advantages claimed for the early sitting up of patients are that it prevents phlebitis, that the patient is not weakened by enforced rest, that recoveries are better, that hernia is less frequent, that vomiting is prevented, and that convalescence is shortened.

THE GREAT ORMOND-STREET HOSPITAL FOR SICK CHILDREN.

THE summer session of lectures and demonstrations, which are free to all duly qualified medical practitioners, will commence on May 7th, when Dr. A. E. Garrod will lecture on Infantile Scurvy. On May 14th Mr. H. Stansfield Collier will give a practical demonstration of some minor operations in children. The lectures and demonstrations will be given every Thursday at the Hospital for Sick Children, Great Ormond-street, London, W.C., and will commence at 4 P.M. A list of subjects and lecturers will be published in our columns week by week.

HÆMATEMESIS IN APPENDICITIS.

HÆMATEMESIS has been described in appendicitis by several French writers but appears to have been almost unnoticed in this country. In his "Cliniques de l'Hôtel Dieu," 1901–02, Professor Dieulafoy devoted a lecture to "Vomito Negro Appendiculaire," in which he reported cases of appendicitis accompanied by abundant hæmatemesis, sometimes so severe that blood entered the air passages and suffocated the patient. All the cases were serious and many of them were fatal. As there were often also jaundice and oliguria, recalling the symptoms of yellow fever ("vomito negro"), he used the designation given above. He regarded the hæmatemesis as a manifestation of general infection or intoxication which lead to the production of small gastric ulcers. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of March 8th Dr. J. Duvergey has described, under the title of "Les Petites Hématémèses de l'Appendicite," a form of hæmatemesis in appendicitis in which the hæmorrhage is slight and not of serious significance. He relates two cases. In the first case he was called in consultation on Nov. 13th, 1905, to a man, aged 52 years, who had always enjoyed good health. On the evening of the 10th he began to feel abdominal pains, which on the 11th became localised to the right side. On the 13th the pain was increased and he vomited twice. The pulse was 90 and the temperature was 100·2° F. The abdomen was not distended and there was no cutaneous hyperæsthesia. On the right side the abdominal muscles were rigid and McBurney's point was tender. The vomit consisted of a slightly brownish liquid mixed with a little mucus, in which floated blackish filaments. Here and there and settled on the bottom were masses like *coffee-grounds. Microscopic examination* of the vomit showed red blood corpuscles for the most part deformed. Dr. Duvergey recommended expectant treatment but knowing the gravity of hæmatemesis in appendicitis he was prepared to operate on the slightest indication. The hæmatemesis ceased and recovery took place in about eight days. On Dec. 26th he removed the appendix which was long, swollen at its extremity, and surrounded by adhesions. In the second case, a youth, aged 19 years, was seized on the night of July 31st, 1907, with violent colic all over the attacked by various oily emulsions, but the utility of this measure is much lessened by the fact that the first intimation of the infection of a house is the report of a case in it and that it is the exception to have a succession of cases of plague in one room. Hence really there are only two ways of escaping plague when once the epidemic has begun—namely, evacuation and inoculation. The former, though largely resorted to by the people themselves, is often unavailable for many reasons; thus we must rely mostly on inoculation. All plague prophylactic is now stored by Maynard's system of bottling, which works without trouble of any kind; tests have shown in 497 brews that no contamination occurs after bottling. Now the results of inoculation are highly satisfactory. Haffkine's antiplague vaccine has been used. No bad results have been reported. From the replies sent out by the numerous medical officers on the subject we see that the health of the inoculated has been, if anything, better since the operation was performed; where the epidemic was severe about 5 per cent. of the inoculated were attacked but only 1 per cent. died. Previous inoculation was found to modify the type of the disease and to reduce its severity greatly. The answers were also unanimous in stating that inoculation was a very great protection against plague and that in no case had any harm resulted and that immunity lasted for about a year. Thus the case mortality and the case incidence have been markedly reduced, no matter where the people lived—in town in their own homes, in camps, or under the best sanitary conditions. Truly a triumphant vindication of Mr. Haffkine's invaluable method of treating plague. Time in this case has certainly brought its undeniable revenge.

LYNN THOMAS AND SKYRME FUND.

THE following subscriptions have been received between April 11th and April 16th by Mr. William Sheen, M.S. Lond., F.R.C.S. Eng. (2, St. Andrew's-crescent, Cardiff), honorary secretary to the fund.

Subscribers of Six Pounds.

West Herts Medical Association, per E. S. H. Hardenberg, Watford.

Subscribers of Five Guineas.

T. Mark Hovell, London.
The Right Hon. Lord Lister, O.M., London.
Warrington Medico-Ethical Society, per Ernest E. Bowden.

Subscribers of Three Guineas.

J. Hughlings Jackson, London.
R. O. Moon, London.

Subscribers of Two Guineas.

W. R. Buckell, Cheltenham.
Professor John Chiene, C.B., Edinburgh.
Ernest Clarke, London.
William Collier, Oxford.
J. Glendinning, Abergavenny.

F. Rigby, Preston.

Mr. William Sheen will be obliged if, in order to insure the correct entry of names, subscribers will inclose their visiting cards.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 24th, 18

THE ordinary and efficient means by which the aberratio of the human mind are detected, are minute observation the individual's conduct, inspection of his written document and protracted conversations to develop his delusions: a these examinations, on many occasions, require to frequently repeated, before the insanity of the person can exposed. For these tedious processes Dr. Burrows[1] has remedy, which must be considered a peculiar endowmen the operation of which constitutes the greatest of mode improvements, and may be viewed as a short cut to t discovery of madness. We find, page 296, that—

"Mania, especially, is characterised by a peculiar odou it is not the *hircum olet* of Horace, but is a smell qu unique, and when once recognised, it can never be mistak for any other; it has been compared to the scent of hent in a state of fermentation, but I know nothing which resembles.

"This odour does not always attend on mania, and differs in intensity. Personal cleanliness of the skin, frequent changes of body-linen, much modify, and perha may remove it. Where it is generated, it is easiest detect by going in the morning into the chamber of the luna before he has risen, and before fresh air has been admitte The maniacal odour is not noticed by every writer on t signs of insanity; nor, as I have said, is it always prese but I consider it a pathognomic symptom so unerring, that I detected it in any person, I should not hesitate to pronoun him insane, even though I had no other proof of it."

This delicate and prodigious discrimination of the olfacto organs, removes other practitioners, not similarly gifted, a distance truly humiliating, and confers on the sim perception of the lowest sense an instantaneous decision a tainted intellect, which physicians, in general, are oblig to explore by the powers of the understanding, by co parison, by reason, and by judgment. We are not informed, exact admeasurement, to what distance this perfume extend but it must follow, that in states of convalescence, emanations will be comparatively feeble, and formidably p dominant in cases of relapse. In the reign of James First, when witchcraft was in fashion, an individual, the name of Hopkin, boasted, that he possessed an infalli tact for the discovery of these agents of the dev and which he actually exercised under the confiden and patronage of those who ought to have known bett of Hodgkin's disease seen at the Pennsylvania Hospital found that a decided eosinophilia had been observed in three of them, 13·2 per cent. in one, 8·8 in another, and 10·6 in the third. The explanation offered is that the eosinophiles are formed in excess in the bone marrow and that they are on their way to be deposited in the glands affected by the lymphadenomatous process.

---

[1] Excerpt from review of "Commentaries on the Causes, For Symptoms, and Treatment, Moral and Medical, of Insanity." George Man Burrows, M.D., Member of the Royal College of Physic of London, etc. London: Underwood. 1823. 8vo, pp. 716.

SCANDINAVIA AS A WINTER HEALTH RESORT.

THE series of articles on Scandinavian Winter Health Stations, being the report of our Special Commissioner, which we commence in another column, are of special interest at the present moment by reason of the visits which the King and Queen are now making to the Courts of Denmark, Sweden, and Norway. At present their Majesties are in Copenhagen. Naturally all British subjects are interested in the countries where the King and Queen may be sojourning, while medical men who have patients likely to receive benefit from a visit to these northern European health resorts will welcome a series of articles on the subject thus early in the year because their patients will have plenty of time to become acquainted with the necessary information and will be able to make their arrangements without undue hurry. The present instalment deals in a general way with the subject of Scandinavia as a health resort and points out the best routes by which to travel as well as giving information regarding the climate and the conditions of life. In subsequent articles it is proposed to deal in detail with some of the more important health stations.

BIRTHS AND DEATHS IN THE PRINCIPAL TOWNS OF EGYPT.

IN Egypt, as far as the native portion of the population is concerned, the birth- and death-rates are both exceptionally high. This has long been recognised but until 1897—when at last a trustworthy census was taken—there was no real foundation for the belief. It is true that in 1882 a so-called *Recensement* was produced but owing to the Arabi disturbance and other causes it was no better than an imperfect estimation. From a return recently issued by the Department of Public Health we learn that the indigenous birth- and death-rates during the year 1907 in 20 of the principal towns of Egypt, and containing in the aggregate a population of 1,530,672, were respectively 43·7 and 36·7 per 1000; the highest birth-rates having been 62·0 at Benha and the lowest 33·9 at Keneh, while the highest death-rate was 47·5 at Fayum and the lowest 23·3 at Damietta. In this connexion it is of interest to note that the last-named town still easily retains its pride of place as the healthiest town in Egypt, the cause of its exceptional salubrity, as was long since pointed out in these pages and elsewhere, being the comparative purity of the water-supply during the low-Nile season, when the bed of the river is little better than an open sewer. Among foreigners, of whom 104,051 were distributed through the 20 towns in numbers varying from 75 at Guizeh to 35,219 at Cairo and 46,118 at Alexandria, the rates were as follows: Births (no record); deaths, highest 153·8 at Assuan, lowest 10·2 at Damanhour; the average death-rate for the 20 towns having been 24·4 per 1000. Among natives the principal causes of mortality were as follows, the figures representing the percentage borne by the disease mentioned to the total number of deaths: dysentery and diarrhœa, 26·2; congenital debility, 10·0; senile debility, 6·3; tuberculosis, 4·8; measles, 4·1; violence, 2·7; malaria, 0·4; plague, 0·3; cholera, *nil*; and "all other diseases," 38·8. The chief causes of death amongst the foreign population were as follows: dysentery and diarrhœa, 17·5; tuberculosis, 7·7; violence, 3·7; typhoid fever, 3·0; small-pox, 2·9; congenital debility, 2·8; senile debility, 2·6; plague, 1·1; other infectious diseases, 7·44; and "all other diseases," 51·3. The total number of deaths due to violence among the natives was 1496; of these 1318 are ascribed to accident, 14 to execution, 151 to homicide, and 13 to suicide. Among the foreigners the total number of violent deaths was 94, accident being responsible for 61, homicide for 15, and suicide for 18. The last table in this useful return refers to the incidence of infectious disease throughout the entire country. It gives the number of cases and deaths that occurred during the twelvemonth under no fewer than 23 heads inclusive of Malta fever, leprosy, meningitis, anthrax, and rabies, the grand total being—cases 11,907 and deaths 9792. Measles and small-pox were by far the most deadly affections that were notified. The first caused 5790 cases and 5456 deaths and the second 2130 cases and 578 deaths.

SIR HENRY CAMPBELL-BANNERMAN.

ALL classes of society and all political parties are alike in sincerely mourning the death of Sir Henry Campbell-Bannerman. To medical men it has long been apparent that the chances of the distinguished patient making effective resistance to his malady were not very good; but if his vitality, under assiduous medical care, had proved equal to his being moved to a more suitable environment, he might have gained a further lease of life. The cardiac weakness, so seriously indicated last autumn, proved, however, a bar to all remedial measures and the patient passed peacefully away in a condition of unconsciousness. It is no exaggeration to say that he died a martyr to duty, for in his physical condition, further depressed as he was by the loss of a beloved wife, the task of governing the country was too great for his powers.

THE PROPOSED REMOVAL OF KING'S COLLEGE HOSPITAL.

A YEAR ago a committee of medical practitioners in South London held a conference with the watching committee of King's College Hospital (which is a subcommittee of the medical members of the managing board having advisory functions concerned with the new buildings) with regard to the administration of the hospital in its prospective locality. The practitioners were represented by the South London Hospitals Committee and this body presented 17 resolutions to the watching committee regarding the control of the hospital when it shall have changed its sphere of activity to South London, framed largely in the desire to promote the ethical interests of "outside" practitioners. 15 of these were accepted by the watching committee but that body found itself unable to recommend the remaining two to the King's College Hospital authorities. These stipulate (1) that every patient on attending a second time at the hospital must bring with him a recommendation signed by a qualified medical practitioner stating that he is a suitable person for hospital treatment from the points of view of his means and of the nature of his malady; and (2) that private wards or nursing homes for paying patients be distinct from the general hospital and not erected or maintained out of the funds given for hospital purposes. We understand that the watching committee felt unable to support the latter resolution in opposition to the views of the King's College Hospital board of management on the subject. With regard to the former proposal the committee considers that practitioners in the neighbourhood of a hospital cannot with the best of intentions be strictly impartial in the distribution of such "letters," especially if they are of opinion that the hospital is in any sense in competition with them. The South London Hospitals Committee, on the other equal to an annual rate of 1·3 per 1000, against 1·6 and 1·4 in the two preceding weeks; the rate from the same diseases in London was also equal to 1·3. No death from any of these epidemic diseases was registered during the week in Tottenham, Ipswich, Handsworth, Bury, or Barrow-in-Furness; the annual death-rates from these diseases ranged upwards, however, to 3·8 in Hastings, 4·1 in Merthyr Tydfil, 4·3 in Rhondda, and 4·9 in Stockton-on-Tees. The fatal cases of whooping-cough in the 76 towns, which had been 203 and 204 in the two preceding weeks, declined to 150 in the week under notice; the highest death-rates from this disease in these towns were 2·0 in Stockton-on-Tees, 2·7 in Northampton, 3·7 in Warrington, and 4·1 in Merthyr Tydfil. The 125 deaths from measles exceeded the number in the previous week by 15; they caused death-rates equal to 1·7 in Birkenhead, 1·8 in Preston, 2·0 in Stockton-on-Tees, and 2·7 in Rhondda. The deaths referred to diphtheria, which had been 62, 52, and 48 in the three previous weeks, rose again during the week to 53, and included 17 in London, five in Manchester and Salford, and three in Birmingham. The fatal cases of scarlet fever also showed a considerable increase upon the numbers in recent weeks, the highest death-rates therefrom being 1·1 in Walsall, 1·5 in West Bromwich, and 2·3 in Hastings. The 29 deaths attributed to diarrhœa showed a distinct decline; and only 14 deaths were referred to "fever," a lower number than in any previous week of this year. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 18 preceding weeks from 5581 to 3121, had further fallen to 2972 on April 11th; only 297 new cases were admitted to these hospitals during the week under notice, against 378, 355, and 315 in the three preceding weeks. One case of small-pox was under treatment in the Metropolitan Asylums Hospitals at the end of the week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had increased from 317 to 351 in the four preceding weeks, declined to 274 in the week under notice, and were 49 below the corrected average number in the corresponding week of the five years 1903–07. The deaths directly referred to influenza in London fell during the week to 37, a decline of 27 from the number in the previous week. The causes of 38, or 0·8 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Leeds, Bristol, West Ham, Hull, Newcastle-on-Tyne, and in three other smaller towns; seven uncertified causes of deaths were, however, registered in Birmingham, five in Liverpool, five in Sheffield, and three in Norwich.

In 76 of the largest English towns 7955 births and 4748 deaths were registered during the week ending April 18th. The mean annual rate of mortality in these towns, which had been equal to 17·4, 16·8, and 15·4 per 1000 in the three preceding weeks, further declined to 15·2 in the week under notice, the lowest rate recorded since the beginning of this year. During the first three weeks of the current quarter the death-rate in these towns has averaged only 15·8 per 1000; the rate in London during the same period did not exceed 15·3. The lowest annual death-rates in the 76 towns during the week under notice were 7·3 in Willesden, 7·7 in Burton-on-Trent, 8·4 in Handsworth, and 8·7 in Walthamstow and in Grimsby; the rates in the other towns ranged upwards to 21·7 in Preston, 21·9 in Rhondda, 22·5 in Coventry, 22·7 in Tynemouth, and 24·2 in Huddersfield. The rate of mortality in London during the week did not exceed 14·7 per 1000. The 4748 deaths in the 76 towns during the week showed a further decline of 36 from the numbers returned in recent weeks, and included 382 which were referred to the principal epidemic diseases, against 488, 445, and 412 in the three previous weeks; of these, 134 resulted from whooping-cough, 127 from measles, 39 from diphtheria, 34 from scarlet fever, 30 from diarrhœa, and 18 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·2 per 1000, against 1·6, 1·4, and 1·3 in the three preceding weeks; the rate from the same diseases in London was equal to 1·3. No death from any of these epidemic diseases was registered last week in Leicester, Derby, St. Helens, Wigan, Rochdale, or in nine other smaller towns; the annual death-rat those diseases ranged upwards, however, to 3·3 in P Furness, 3·8 in Reading, 3·9 in Birkenhead, and Stockton-on-Tees. The fatal cases of whooping-coug 76 towns, which had been 204 and 150 in the two p weeks, further declined to 134 in the week under notic highest death-rates from this disease in these towns w in Sunderland, 1·5 in Bootle and in Sheffield, 1 Reading, and 2·5 in Barrow-in-Furness. The 127 from measles showed a further increase of two up numbers in the two previous weeks; they caused deat equal to 2·0 in Salford, 2·6 in Birkenhead, 2·7 in P and 6·9 in Stockton-on-Tees. The deaths from diph which had been 48 and 53 in the two preceding declined during the week to 39, and included 14 in Lo and two each in Norwich, West Bromwich, Live and Manchester. The 34 fatal cases of scarlet fever s a decline of seven from the number in the previous they again showed the highest annual rate, 1·1 per 10 Walsall. The 30 deaths attributed to diarrhœa exc those in the previous week by one, and the 18 deaths ref to "fever" showed an increase of four. The numb scarlet fever patients under treatment in the Metropol Asylums and London Fever Hospitals, which had ste declined in the 19 preceding weeks from 5581 to 2972, further declined to 2837 on April 18th; 328 new cases w however, admitted to these hospitals during the week u notice, against numbers declining from 378 to 297 in the preceding weeks. One case of small-pox was under treatm in the Metropolitan Asylums Hospitals at the end of the we The deaths in London referred to pneumonia and o diseases of the respiratory organs, which had been 351 274 in the two preceding weeks, were again 274 in the w under notice, and were 40 below the corrected aver number in the corresponding week of the five years 1903- The deaths directly referred to influenza in London were corresponding with the number in the previous week. T causes of 42, or 0·9 per cent., of the deaths registered the 76 towns were not certified either by a registered medic practitioner or by a coroner. All the causes of death we again duly certified in London, Leeds, Bristol, West Ha Hull, Bradford, Leicester, and in 44 other smaller town five uncertified causes of death were, however, registered Liverpool, four in Birmingham, and three both in Manchest and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the princip Scotch towns, which had been equal to 18·5, 19·4, an 19·7 in the three preceding weeks, declined again to 18· in the week ending April 11th, but exceeded by no less tha 3·4 the mean rate during the same week in the 76 larg English towns. Among the eight Scotch towns the death rates during the week ranged from 14·2 and 14·8 in Leit and Perth, to 19·5 in Dundee and 21·1 in Glasgow. The 66 deaths in these eight towns showed a decline of 31 from th number returned in the previous week, and included 87 which were referred to the principal epidemic diseases, against 114 and 97 in the two preceding weeks; of these, 40 resulted from measles, 13 from whooping-cough, 10 from "fever," 10 from diarrhœa, and seven both from scarlet fever and diphtheria, but not one from small-pox. These 87 deaths were equal to an annual rate of 2·5 per 1000, against 1·3, the mean rate during the week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 58 and 35 in the two preceding weeks, rose again during the week to 40, of which 32 occurred in Glasgow, five in Edinburgh, and two in Paisley. The 13 deaths from whooping-cough showed a considerable decline from recent weekly numbers, and included seven in Glasgow and three in Edinburgh. The 10 deaths referred to "fever" exceeded the number in the previous week by three, nine being certified as cerebro-spinal meningitis and one as enteric; five were recorded in Glasgow, two both in Edinburgh and Leith, and one in Dundee. The 10 deaths attributed to diarrhœa were fewer than in any recent week, including five in Aberdeen and four in Glasgow. Of the seven fatal cases of diphtheria six occurred in Glasgow; and of the seven deaths from scarlet fever five were recorded in Dundee and two in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had declined in the three preceding weeks from 158 to 114, rose again in the week under h others the people rarely show any objection to rats ng destroyed.

Vith regard to the employment of Haffkine's antiplague oulation this has been encouraged by every possible means. e local officers concerned have freely offered themselves as jects for the method whenever necessary. The results re uniformly favourable as regard the small number of sequent attacks; no ill effects on the general constitution re caused, whilst patients have declared themselves cured chronic rheumatism and malaria thereby. Of the efficacy evacuation in plague epidemics there has never been any ıbt. By securing voluntary evacuation the Commissioner the Pegu Division secured good results, whilst where there s delay in this measure as at Prome and Mandalay there s great mortality. Lastly, with respect to the variations incidence of plague the Sanitary Commissioner of Burma ıarks in regard to meteorological data that a comparaely low average temperature with great humidity is more mical to plague prevalence than a higher temperature h less humidity, providing the daily maximum temperae in the latter case does not often exceed 96°.

olonel King concludes his admirable report on plague h some weighty considerations as to its prevalence. He s one of the first to recognise the rôle played by rats, in 1896 he issued a circular for public information in ich it was stated that rats die from this disease and that n the bodies of these animals being found they should be efully burnt" He shows how in ancient times the Hindu stras gave definite intimation of the connexion between s and plague. He again urges the possibility of the estinal canal of man playing a part in the transmission of disease; he draws attention also to the possible rôle of e fly, particularly in pneumonic cases, and also to that dust as a means of infection, concerning which Klein lieves in the prolonged vitality of the plague microbe in nd. But he considers it non-proven at present that the rat is e sole medium of transmission, although he is of opinion that an is the chief introducing agent and the rat is the dreaded sseminator. The prime factor to recognise in the matter prevention is that the utmost effort must be given to the rveillance of a threatened population and the control of ose infected. To meet plague an organised sanitary service essential capable of contending each inch of territory the discriminatory use of all sound methods. There ıst be systematised surveillance (with full liberty of the erson) of, usually, controllable human beings, the consenent early sanitary treatment of imported cases in unfected localities, and the consequent prevention of infecon of rats which are uncontrollable disseminators of fection. To obtain a sufficient staff for such a course of ction may be expensive but it will be the cheapest in the nd. The above report is presumably the last one that olonel King will write; we can only say that this wellnown officer has served his Government well throughout is career in India, and that in losing him the Government f India will lose a pre-eminently wise and able sanitarian ho by his ungrudging labour has justly earned the respect f all who have worked with him.

Bombay.

Dr. J. A. Turner, the executive health officer of the unicipality of Bombay, in his report for 1906 deals with he subject of plague administration. The campaign against ats was continued during the year, 231,392 rats having been collected and sent to the Government laboratory at Parel. These included live rats, dead rats in a putrid condition, and all rats sent on Sundays and holidays Very few live rats were examined, as only a very small proportion of them were found to be infected. Of the above number sent 131,322 rats were examined, out of which number 18,572 rats were found to be infected. The larger number were found to infected during the first five months of the year. In January, at the request of Major E. Jennings, I.M.S., the superintendent of plague operations, 18 persons were sent on behalf of the district municipalities for instruction in the use and method of employing the "common-sense rat exterminator." Their instruction seems to have been very complete in all its details. It was brought to the notice of the executive health officer that rats migrated in large number from the steamers at anchor in the docks, and from these vessels to the Bundes, and measures were taken to counteract this migration by poison; whilst the corporation was requested to move the Government to issue a general resolution that no ship should be allowed to enter the Bombay docks before it is operated with the "common-sense rat exterminator" whilst it is in the harbour. Although this measure would cause a certain amount of inconvenience to the navigation traffic yet it would check the rat migration and therefore Dr. Turner urges the Government to enforce the measure suggested. Another measure to which great attention was paid was that of inoculation, in all 10,740 persons having been so treated. No friction was experienced, the divisional health officers devoting much of their spare time to explaining the advantages of the operation to illiterate persons. Railway passengers were also inspected at the instance of the health officer at Poona or other convenient stations, this measure being carried out smoothly and without causing any detention of, or inconvenience to, passengers. This method in 1906 was the means of detecting outside infection in various parts of the city and has thus helped the health department in controlling the spread of the disease.

Dr. N. H. Choksy gives an account of the results of the treatment of plague by the serum treatment and by adrenalin chloride. Three serums were employed. With respect to the Yersin-Roux serum, after rejecting those cases unfit for treatment, 60 cases were chosen, of which half were kept as "controls." In the 30 cases treated with the serum the rate of case-mortality was 46·6 per cent, whilst in the "controls" the rate of mortality was 66·6 per cent., there thus being a saving of life to the extent of 20 per cent. in the former. Comparing these results with those of 1905 there was a difference in favour of the serum of 13·6 per cent. Again, the results obtained from the employment of Professor Tavel's serum were found to be just as efficacious. With regard to the Japanese serum the cases are too few to arrive at any conclusion.

We come now to the results of the adrenalin treatment. This drug was found to be especially useful in supporting and sustaining the action of the heart during the most critical period of the illness. Dr. Choksy, amongst other conclusions, draws attention to the following facts: 1. That adrenalin chloride solution (1 in 1000) is of great use in the treatment of plague; it is most useful when employed early. The dose is best given as from 20 to 30 minims internally every two hours, or 20 minims every hour in very grave cases. It should not be administered with any other drug but given in plain water or, better, in normal salt solution. No alcohol should be used. Infants and children bear it well in proportionate doses but caution is required in advanced age. It is non-accumulative and it can be also employed subcutaneously in doses of from five to ten minims every two hours. Finally, the administration of the remedy, together with the use of the Yersin-Roux serum, constitutes the ideal treatment of the disease. A fair trial was also made of another preparation of the suprarenal gland—namely, the extract rena-glandin. The case mortality in 180 patients was 77·2 per cent., or 5 per cent. higher than that of adrenalin. An improved preparation was used subcutaneously during 1906, and in 36 patients the mortality was 66·6 per cent.—i.e., about the same as that of adrenalin used in the same way. This preparation, therefore, is deserving of further trial.

A very interesting report has been furnished by Lieutenant-Colonel W. B. Bannerman, Director of the Bombay Bacteriological Laboratory (formerly the Plague Research Laboratory), for the nine months ending Dec. 31st, 1906. During this period 119,207 doses of Haffkine's antiplague vaccine were sent out to the territories comprised under the titles British India, Native States, and Countries outside India. The demands for the prophylactic in 1906 fell in number, probably for the reason that the people hoped that some more agreeable method of protection from plague might be discovered by the appointment of the Plague Research Commission. Now, however, that the result of the investigations of the latter is known there are signs that inoculations will once more come to the front as the sheet anchor of the administrator and the sanitarian in their fight with plague. The Plague Commission proved amongst other things: (1) that plague is conveyed from rat to rat, and from rat to man, by means of fleas; and (2) that plague houses are infective only so long as they contain fleas. So to obtain protection from plague we must get rid of rats or fleas or of both. The former, as Lieutenant-Colonel Bannerman remarks, has been tried by many, yet with disappointing results. To be successful the rat population must be destroyed before the advent of plague; it is useless whilst an epidemic is raging in any village. Fleas have been the Burmese Expedition in 1886–87 (medal and clasp). He was gazetted lieutenant-colonel in 1900 and for some time was professor of midwifery at Calcutta Medical College and also obstetric physician and surgeon at the Eden Hospital, Calcutta.

ARMY MEDICAL SERVICE EXAMINATIONS.

An examination of candidates for not less than 30 commissions in the Royal Army Medical Corps will be held on July 29th and following days. Applications to compete should be made to the Secretary, War Office, London, not later than July 20th, on which date the list will be closed. Candidates who are over the regulated limit of age at the date of the examination will be permitted to deduct from their actual age any period of service in the field after Oct. 1st, 1899, that they could reckon towards retired pay and gratuity, if such deduction will bring them within the age limit. The presence of candidates will be required in London from July 27th.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on April 14th, Inspector-General W. H. Lloyd, R.N., being in the chair, the sum of £55 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

THE RESEARCH DEFENCE SOCIETY.

To the Editor of THE LANCET.

SIR,—A society has been formed, with the name of the Research Defence Society, to make known the facts as to experiments on animals in this country; the immense importance to the welfare of mankind of such experiments; and the great saving of human life and health directly attributable to them. The great advance that has been made during the last quarter of a century in our knowledge of the functions of the body and of the causes of disease would have been impossible without a combination of experiment and observation.

The use of antiseptics and the modern treatment of wounds is the direct outcome of the experiments of Pasteur and Lister. Pasteur's discovery of the microbial cause of puerperal fever has in itself enormously reduced the deaths of women in childbirth. The nature of tuberculosis is now known and its incidence has materially diminished. We owe the invention of diphtheria antitoxin entirely to experiments on animals.

The causes of plague, cholera, typhoid fever, Mediterranean fever, and sleeping sickness have been discovered solely by the experimental method. Not only have a large number of drugs been placed at our disposal but accurate knowledge has replaced the empirical use of many of those previously known. The evidence before the Royal Commission has shown that these experiments are conducted with proper care; the small amount of pain or discomfort inflicted is insignificant compared with the great gain to knowledge and the direct advantage to humanity.

While acknowledging in general the utility of the experimental method, efforts have been made by a section of the public to throw discredit on all experiments involving the use of animals. The Research Defence Society will therefore endeavour to make it clear that medical and other scientific men who employ these methods are not less humane than the rest of their countrymen who daily, though perhaps unconsciously, profit by them. The society proposes to give information to all inquirers, to publish *précis*, articles, and leaflets, to make arrangements for lectures, to send speakers, if required, to debates, and to assist all who desire to examine the arguments on behalf of experiments on animals. It hopes to establish branches in our chief cities and thus to be in touch with all parts of the kingdom, and to be at the service of municipal bodies, hospitals, and other public institutions.

The society was formed on Jan. 27th of the present year, and already numbers more than 800 members. It is not an association of men of science or of medical men alone; its membership has been drawn from all departments of public life and includes representatives of every class of educated Englishmen and Englishwomen, including many who have taken an active part in the prevention of cruelty to animals. This fact is in itself a remarkable protest against the which have been made on the researches that the been formed to defend.

The annual subscription is 5*s.* to cover working but larger subscriptions or donations will be gladly The acting honorary treasurer, *pro tem.*, is Mr. J. Pattisson, C.B. (of the Lister Institute), and an account in the society's name has been opened with Messrs. Coutts and Co., 440, Strand. The honorary secretary is Mr. Stephen Paget, 70, Harley-street, London, W., to whom all communications should be addressed.

I am, Sir, yours faithfully,
CROMER,
President.

*** We have the pleasure to support Lord Cromer's arguments in a leading article. We append an alphabetical list of the Vice-Presidents which sufficiently shows the powerful and many-sided support which the movement has already received.—ED. L.

The Duke of ABERCORN, K.G.
Sir T. CLIFFORD ALLBUTT, F.R.S.
Sir L. ALMA TADEMA, R.A.
Sir WILLIAM ANSON, Bart., D.C.L., M.P.
The Right Hon. Lord AVEBURY, F.R.S.

The Right Hon. Sir ALFRED WILLS.
The Rev. HENRY GEORGE WOODS, D.D. (Master of the Temple).

DEATHS DURING ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In your issue of April 11th Mr. H. Bellamy Gardner criticises Dr. F. J. Waldo's article in THE LANCET of March 21st. He summarises the article in question in the following way:—(*a*) Dr. Waldo complains that the Registrar-General's statistics of deaths under anæsthetics are not of much use from a statistical point of view "because they do the terror and extermination of innocent old women. kin was too cunning to divulge his secret, and this t perished with the possessor. It is not impossible t the witch-finder was led by the nose to these imant discoveries, for we see no reason why a peculiar vium should not equally issue from a witch as from a atic. In order to estimate duly this pathognomic symptom, have inquired of those practitioners, whose experience has n most extensive in this department of the profession, they univocally deny any knowledge of this scent, and ily state, that it cannot be a sufficient criterion to send pers to gentlemen's houses, or to warrant a certificate for seclusion of an individual in a private asylum; and we fully persuaded, that a jury *de lunatico inquirendo*, and Metropolitan Commissioners, would reject, with scorn indignation, any evidence established on this conmal essence or attar of insanity.

MEDICINE AND THE LAW.

The Medical Man and the Coroner.

T a recent inquest at Worcester the city coroner, Mr. B. Hulme, commented unfavourably upon the conduct of E. Walpole Simmons, the Poor-law medical officer, in the owing circumstances. A labourer named Barnett had tained a fall in his cottage through intoxication and had tured a rib. He had been recommended by Mr. W. G. nett to attend at the infirmary and had done so but l developed pneumonia, from which he died 12 days r receiving the original injury. He had also dised mental symptoms which caused Mr. Bennett give his relatives an emergency order for his admission a lunatic asylum, which was not made use of owing to e patient being too ill from the pneumonia to be moved th safety. After death had taken place Dr. Simmons, o apparently had taken charge of the case with a view to e removal of the patient under the *emergency order*, gave certificate which ascribed death to the pneumonia following on the fracture of a rib, and the coroner upon this being ought to his notice by the registrar held an inquest. At is he found fault with the medical man because he had t communicated with him (the coroner) directly, his quesns and observations, with the answers of Dr. Simmons, ing thus reported in the *Worcester Daily Times* of March 14th. Why was this case not reported to me?" "Because I ned a death certificate knowing it would come to you." I disagree with you there. Here is a man who dies as the ult of an injury, and I ask you why it was not reported to e?" "Why, because I deliberately put broken ribs on the tificate so that it should be reported to you." "You ere depending upon somebody else to do your duty. Your ty is that when there is a case for inquiry you ought report it yourself." "It was an absolute certainty at it would come to you." "Only by a round-about ay. You inform Mr. Everton [presumably the registrar of aths] and Mr. Everton has to inform me but he is der no obligation to do so." As a result of these marks on the part of the coroner the Worcester edical Society held a meeting and instructed its honorary cretary to write to the coroner and to ask him for his thority for saying that it is the duty of medical men to tify the coroner in cases such as that described, with the rther request that, unless he could show legal authority n his side, he should publicly withdraw censure based on an assertion of failure of duty on the part of Dr. mmons. The coroner in his reply denied having "censured" and said that there had been a discussion only as to hat course should have been followed. With regard to the edical man's duties he wrote as follows:—

> It is the common law duty of every person in attendance upon or about the deceased to give information to the coroner. The medical attendant is clearly one such person and he should therefore in a case where there is any doubt as to the death being due to natural causes either withhold his certificate as authorised by Section 39 of the Registration of Births and Deaths Act, 1874, and give notice to the coroner, or if he gives such a certificate he should at the same time communicate with the coroner drawing his attention to the circumstances of the case.

No doubt from the point of view of the Worcester coroner and of other coroners the course suggested above would be a convenient one, and we entirely sympathise with Mr. Hulme in his undoubted desire that the functions of his important office should be performed efficiently. He forfeits our sympathy, however, where he assumes a tone towards a medical witness for the assumption of which there is no just cause and when he seeks to impose by his own authority upon medical practitioners duties which the law does not assign to them. We believe, moreover, that his observations at the inquest of which the report is before us, with regard both to the signing of the certificate and to other matters, were not of a character likely to produce that mutual goodwill and conciliation by which alone the existing Coroners Act can be administered with reasonable smoothness. Dr. Simmons placed on record in an authoritative document information which, as he had every reason to believe, would in due course reach the coroner and upon which the coroner might decide to hold an inquest and which might guide him in obtaining the evidence necessary for doing so. He might have done differently even to following one of the courses which the coroner recommends, and perhaps by tact and conciliation a coroner might obtain the adoption of such a practice within his district. On the other hand, Dr. Simmons might have declined to give a certificate and refused to give any information to anyone except only upon being summoned as a witness to the inquest. We do not say that such a procedure would be commendable but we doubt the coroner having any power to compel any other should the medical practitioners at Worcester choose to adopt it. With all respect to Mr. Hulme, the medical man is not quite in the same position as "the other persons in attendance upon or about the deceased." He is there by virtue of his profession and when the law requires of him in other matters that he should give information as to what he has observed professionally it lays down the course which he is to pursue in plain terms and assigns him a fee for doing that which he is ordered to do. The giving of information not required of him thus plainly by the law is, or may be, a delicate matter. His patient's affairs are not to be revealed lightly and although no medical man would hesitate as to his duty in his patient's interest, as, for example, if he believed that negligence on the part of the patient's relatives had accelerated death, he might think reasonably that it was undesirable to take an active part in procuring the holding of an inquest by writing to the coroner suggesting it, and the course adopted by Dr. Simmons in the particular case under discussion as a matter of fact gave the coroner the opportunity for considering whether he should hold an inquest, while the medical man did that which was legally and ethically correct. A revision of the law in such matters is very much to be desired but it is not likely to be accelerated by medical men doing voluntarily and without reward that which *ought* to be done after a prescribed form for a suitable fee; such voluntary action will never be universal and so the desired results will not be obtained with certainty and precision.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8575 births and 4764 deaths were registered during the week ending April 11th. The mean annual rate of mortality in these towns, which had been equal to 17·4 and 16·8 per 1000 in the two preceding weeks, further declined to 15 4 in the week under notice, a lower rate than had prevailed in any previous week of this year. During the 13 weeks of last quarter the annual death-rate in these towns averaged 18·0 per 1000; the mean rate in London during the same period did not exceed 17 6. The lowest annual death-rates in the 76 towns in the week under notice were 6·1 in Handsworth, 9·2 in Barrow-in-Furness, 9·5 in Leyton and in Tottenham, and 9·9 in Walthamstow; the rates in the other towns ranged upwards to 22·3 in Rhondda, 22·9 in Smethwick and in Rochdale, 23·3 in Norwich, and 27·6 in Hanley. The rate of mortality in London during the week did not exceed 14·7 per 1000. The 4764 deaths in the 76 towns during the week showed a further decline of 438 from the numbers returned in the two preceding weeks, and included 412 which were referred to the principal epidemic diseases, against 485 and 445 in the two previous weeks; of these, 150 resulted from whooping-cough, 125 from measles, 53 from diphtheria, 41 from scarlet fever, 29 from diarrhœa, and 14 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were patients in most instances free of all pits and scars (two patients showed two small pits each on the face).

In future I intend to further push the mercury during the first three days as it is the immediate influence which is so necessary. From experimentation I find that the lethal dose of mercuric chloride is 1 in 1,000,000 in ten minutes, for the bacillus coli suspended in water in quantities of 200,000 per cubic centimetre, at a temperature of 98° F. Also, that all things being equal, the lethal power of $HgCl_2$ is proportionate to the temperature at which the germicidal action takes place. It is very probable that the ingestion of 30 grains of mercury with chalk per day produces at any rate a 1 in 500,000 solution of mercury in the blood (10 stones = 980,000 grains). The spirochæta pallida we know is very susceptible to the influence of mercury; these experiments with variola appear to show that the micro-organism of small-pox (whatever it may be, but probably also a protozoon) is also susceptible. Mercury, in the form in which it exists from the absorption of mercury with chalk from the alimentary canal, cannot be said to exert an active germicidal influence over all forms of micro-organisms, but possibly the biological processes of the spirochæta pallida and the variola organism (?) can engender a bactericidal activity in the comparatively inert circulating mercury; possibly other pathogenic protozoa can also do this. It seems highly probable that mercury has been used before for the treatment of small-pox, but I can find no reference, and the text-books make no reference of it.

It is obviously unsound to draw conclusions from the results of only eight cases, which might all have taken the simple course they did without any medication, but still the results appear worth recording, in the hope that others may be tempted to try this remedy which, at any rate, is harmless. The conclusions drawn are: (1) ten grains of mercury with chalk three times a day by the mouth, continued for six days, produces no symptoms of poisoning in small-pox; and (2) the drug appears to have a marked action in modifying and reducing the severity of the disease.

I am, Sir, yours faithfully,

V. B. NESFIELD, F.R.C.S.,
Captain, I.M.S.; Medical Officer 2nd 7th Gurkha Rifles, Quetta.

April 3rd, 1903.

THE INHALATION TREATMENT OF CONSUMPTION AND "CATARRH."

To the Editor of THE LANCET.

SIR,—The form of inhalations usually prescribed nowadays is that in which volatile drugs are administered through the medium of inhaled steam. This no doubt benefits many mild cases of nasal catarrh and bronchitis, but the relief afforded is most probably due to the soothing effect of the warm moist air inhaled rather than to any action of the drugs placed in the inhaler. To reach the deeper part of the respiratory tract and to produce an effective antiseptic action inhalations must be given of air impregnated with the vapour of volatile drugs without the presence of an undue quantity of moisture. The difficulty and trouble required to obtain a good result have hitherto led to the unpopularity of this method in the medical profession, and want of a proper understanding of the right way in which to carry out inhalation treatment has sometimes led to bad results when it has been tried. Nowadays the treatment is often prescribed in a simple form, as with a small inhaler fitted over the mouth and nose and containing a small sponge charged with volatile antiseptics. These forms of treatment are exceedingly mild and the results obtained, though useful, are not usually very striking.

Some years ago Hassall made considerable advances in the subject and showed that it was possible to thoroughly impregnate the air of a closed room with volatile antiseptics so that a patient subsequently using the room could not avoid drawing a definite quantity of the substances right down into the lungs during the ordinary process of breathing. But such treatment necessitated the use of special inhalation rooms which could not be always placed at the disposal of the patients unless they left their homes, and indeed in most cases would be difficult to arrange in a private house. However, his experiments showing the readiness with which certain drugs capable of destroying bacilli can be volatilised from extensive surfaces when aided by warm air currents made it apparent that this principle was of great importance and only wanted the invention of a suitable apparatus to be of very great use in the treatment of diseases of the lungs and air passages.

On turning my attention to this question, in an endeavour to better the results I had obtained with simple forms of apparatus, it occurred to me that the inconvenience of impregnating the air of a whole room with antiseptics could be avoided by using instead the air of a moderately sized portable chamber, so that patients could breathe such impregnated air through a simple tube and face-piece. Consequently I have had such a chamber made about 3½ feet high and 1½ feet in width and depth, and rendered airtight with the exception of an inlet and outlet tube, both of which are guarded with valves. In it wide strips of Turkish towelling are suspended from side to side in such a manner that the air current from the inlet to the outlet is bound to come freely into contact with the exposed surface of the towelling. By saturating the strips of towelling with solutions of a known quantity of various volatile substances and closing the chamber the air in it becomes thoroughly impregnated with the vapours given off and can be breathed by the patient who adjusts the face-piece over his mouth and nose and inspires and expires in the ordinary way. The length of time the inhalation is continued depends on individual cases and must, of course, be carefully regulated.

There is no discomfort in the use of the apparatus as each patient can adjust the face-piece himself, and should he not like the *strangeness of breathing through a tube at first* he can readily remove the face-piece and breathe the outer air should he so desire. Moreover, by attaching a cylinder containing compressed air to the inlet tube a constant stream of air impregnated with the volatile antiseptics contained in the chamber can be obtained through the face-piece and inhaled with comfort; I am inclined to think that experience will show that this method of using inhalation chambers is the best one. The volatility of substances such as creosote may be greatly increased by raising the internal temperature of the chamber either by a suitable arrangement of electric lamps or by warming the current of air passing into the chamber.

It is unquestionable that every method of inhalation treatment *must be continuous if it is to be effective*, and there is no doubt that greater progress has not been made with this form of medication because it has been tried with unsuitable apparatus. There is all the difference between taking a few intermittent breaths through a small, poorly charged inhaler and continuously breathing purified and medicated air for an hour or so at a time. The reputed success of Hassall's chambers was no doubt due to his appreciation of this essential principle of inhalation treatment, and I have every hope that my portable inhalation chamber will give results as good.

I am, Sir, yours faithfully,

EDWIN ASH.

Harley-street, W., April 20th, 1903.

MALIGNANT DISEASE OF THE CÆCUM.

To the Editor of THE LANCET.

SIR,—Everyone interested in the treatment of malignant disease of the large intestine will have read Mr. Charters J. Symonds's third Lettsomian lecture[1] with much profit and pleasure. We venture, however, to put forward some remarks on points which seem to us to be of more importance than is apparently attached to them by the lecturer.

Throughout the lecture Mr. Symonds makes repeated references to the excision of glands, but we have been quite unable to understand what *has been the* extent of gland removal in his cases. The anatomy of the lymphatics in this region has been worked out by many observers and there is a sufficiently precise nomenclature in use. It is unfortunate that the clearness of the description of the cases is marred by the absence of definite statements as to the gland groups dealt with. The term "glands close to the spinal column," without reference to their position with regard to the ileo-colic vessels or to the duodenum, is vague and might well denote the lumbar glands, which cannot be intended. The glands invaded, or likely to be invaded, in carcinoma of the cæcum are those which lie on and about the ileo-colic artery and its branches, extending upwards as far as the origin of the artery from the superior mesenteric in front of the duodenum, a clearly circumscribed group not extending into the mesentery, except at its extreme lower end. We are unable to imagine the presence of diseased glands in the mesentery or near the aorta except in cases of advanced and inoperable disease.

In considering the limit of operation Mr. Symonds asks how far should enlarged glands set a limit to the question of resection, and says, "Theoretically a gland as large as a ice to 128, and exceeded by eight the number returned the corresponding week of last year. The causes of or 3·3 per cent., of the deaths in these eight towns ing the week were not certified or not stated; in the 76 glish towns the proportion of uncertified causes of death he same week did not exceed 0·8 per cent.

---

[1] THE LANCET, April 4th, 1903, p. 936.

The annual rate of mortality in eight of the principal tch towns, which had been equal to 19·7 and 18·8 per 0 in the two preceding weeks, further declined to 16·4 in week ending April 18th, but exceeded by 1·0 the n rate during the same week in the 76 large English ns. Among the eight Scotch towns the death-rate ing the week ranged from 12·9 and 13·8 in Leith and nburgh to 16·7 in Greenock and 18·0 in Glasgow. The deaths in these eight towns showed a further decline of from the numbers returned in the two preceding weeks, l included 77 which were referred to the principal demic diseases, against 114, 97, and 87 in the three vious weeks; of these, 36 resulted from measles, from whooping-cough, 11 from diarrhœa, six m "fever," five from scarlet fever, and one from htheria, but not one from small-pox. These 77 deaths e equal to an annual rate of 2·2 per 1000, against 2, the mean rate during the week from the same diseases the 76 English towns. The fatal cases of measles in the ht Scotch towns, which had been 35 and 40 in the two ceding weeks, declined again to 36 in the week under ice, of which 23 occurred in Glasgow, six in Edinburgh, e in Paisley, and two in Aberdeen. The 18 deaths from ooping-cough exceeded the number in the previous ek by five, and included 13 in Glasgow. Of the deaths attributed to diarrhœa six were returned in lasgow and two in Dundee. The six deaths referred "fever" showed a decline of four from the number in e previous week, all being certified as cerebro-spinal eningitis, four occurred in Glasgow and one each in Edinurgh and Leith. Two of the five fatal cases of scarlet ever and the death from diphtheria were recorded in lasgow. The deaths referred to diseases of the respiratory gans in the eight towns, which had been 114 and 128 in he two previous weeks, declined again to 121 in the week nder notice, but exceeded by 17 the number returned in he corresponding week of last year. The causes of 27, or ·7 per cent., of the deaths in these eight towns during the eek were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death in the ame week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 27·4 and 26·0 per 1000 in the two preceding weeks, declined to 22·5 in the week ending April 11th. During the 13 weeks of last quarter the death-rate in Dublin averaged 25·5 per 1000, the mean rate during the same period being only 17·6 in London and 18·3 in Edinburgh. The 170 deaths of Dublin residents registered in the week under notice showed a further decline of 27 from the high numbers returned in recent weeks, and included nine which were referred to the principal epidemic diseases, showing an increase upon recent weekly numbers. These nine deaths from epidemic diseases were equal to an annual rate of 1·2 per 1000, the death-rate during the week from the same diseases being 1·3 in London and 1·5 in Edinburgh. These nine deaths in Dublin included four from measles, three from diarrhœa, and one each from scarlet fever and whooping-cough, but not one either from diphtheria, "fever," or small-pox. The four fatal cases of measles exceeded the number returned in any previous week of this year. The 170 deaths from all causes in the city during the week included 23 of infants under one year of age and 46 of persons aged upwards of 60 years; both these numbers were below those returned in any recent week. Seven inquest cases and five deaths from violence were registered, and 75, or 44·1 per cent., of the deaths occurred in public institutions. The causes of four, or 2·4 per cent., of the deaths registered in the city during the week under notice were not certified; all the causes of death in London were duly certified, while in Edinburgh the proportion of uncertified deaths was equal to 4·7 per cent.

The annual rate of mortality in Dublin, which had been equal to 27·4, 26·0, and 22·5 per 1000 in the three preceding weeks, rose again to 23·1 in the week ending April 18th. During the first three weeks of the current quarter the death-rate in Dublin averaged 23·9 per 1000; the mean rate during the same period did not exceed 15·3 in London and 15·6 in Edinburgh. The 175 deaths of Dublin residents registered in the week under notice showed an increase of five upon the number returned in the previous week, and included seven which were referred to the principal epidemic diseases, a decline of two from the number in the previous week. These seven deaths were equal to an annual rate of 0·9 per 1000, against 1·3 and 1·5 from the same diseases in London and Edinburgh; they included three from measles, three from whooping-cough, and one from scarlet fever, but not one either from diphtheria, "fever," diarrhœa, or small-pox. The fatal cases of measles showed a decline of one from the number in the previous week, while those of whooping-cough showed an increase. The 175 deaths from all causes in the city during the week included 25 of infants under one year of age and 51 of persons aged upwards of 60 years; both these numbers exceeded those returned in the previous week. Five inquest cases and four deaths from violence were registered, and 67, or 38·3 per cent., of the deaths occurred in public institutions. The causes of nine, or 5·1 per cent., of the deaths registered in the city during the week under notice were not certified; all the causes of death in London last week were duly certified, while in Edinburgh the proportion of uncertified deaths was equal to 7·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: G. Price to the *King Alfred;* and H. G. T. Major to the *Donegal.*

ARMY MEDICAL SERVICE.

Surgeon-General William J. Charlton is placed on retired pay (dated, April 11th, 1908). Colonel John C. Dorman, C.M.G., to be Surgeon-General vice W. J. Charlton (dated, April 11th, 1908). Lieutenant-Colonel Alfred Peterkin, from the Royal Army Medical Corps, to be Colonel, vice J. C. Dorman, C.M.G. (dated, April 11th, 1908). Colonel Charles Seymour is placed on retired pay (dated April 12th, 1908).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Henry K. Allport is placed on temporary half-pay, on account of ill-health (dated April 22nd, 1908). Lieutenant-Colonel Henry K. Allport, from temporary half-pay, retires on retired pay (dated April 22nd, 1908).

Lieutenant-Colonel Denham F. Franklin retires on retired pay (dated April 22nd, 1908).

Lieutenant-Colonel D. Hennessy, commanding the Station Hospital, Deolali, has been granted privilege leave till June next.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Frederick H. Appleby, having reached the age for retirement, ceases to belong to the Army Medical Reserve of Officers (dated April 2nd, 1908).

The under-mentioned Surgeon-Captains to be Surgeon-Majors (dated April 4th, 1908): George Melville and Lewis W. Pockett.

The notification in the *London Gazette* of March 3rd that Surgeon-Captain Samuel M. Sloan ceased to belong to the Army Medical Reserve of Officers is cancelled.

MENTIONED IN DESPATCHES.

In despatches published in the *Gazette of India* relating to the Zakka Khel campaign the name of Lieutenant-Colonel M. W. Kerin, R.A.M.C., is mentioned.

THE KING'S BIRTHDAY.

Notice is given in the *London Gazette* that the King's birthday will be celebrated in London and at all home stations on June 26th. At all other stations His Majesty's birthday will be celebrated on Monday, Nov. 9th.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Francis S. Peck, I.M.S., on board the R.M.S. *Persia* in the Mediterranean on April 9th. He was buried at sea. The deceased officer, who was in his fifty-first year, was educated at Clifton College and received his medical training at the Bristol Medical School and St. Thomas's Hospital. He qualified as L.R.C.P. Edin. in 1880, having taken the M.R.C.S. Eng. in the previous year. He entered the Indian Medical Service in 1880 and served with

NOTES UPON HEALTH RESORTS.

SCANDINAVIAN WINTER HEALTH STATIONS.

(By a Special Commissioner.)

Scandinavia in winter is to most English physicians a *terra incognita.* Much of the favour long extended to the Riviera, Egypt, and Alpine resorts for winter residence has been the direct outcome of the recommendations of members of the medical profession. Now that many of the pleasant resting places and health stations which formerly devoted their first and chief attention to the requirements of the invalid and health-seeker are being invaded by wealthy tourists, sportsmen, and others, it may be not inopportune to consider whether new and desirable climatic centres are not available. Your Commissioner has therefore investigated by personal inquiry and direct observation the attractions and conveniences suited to the tastes and requirements of English patients which are now being offered by Norway and Sweden for winter residence.

These countries are well known and highly prized by many who have visited them in summer, but it must be clearly stated at once that opinions formed from conditions then existing can afford no trustworthy guide as to the methods of life and conditions of climate prevailing during the months of winter. In these articles it is proposed to limit consideration, as far as is possible, to Scandinavia in winter.

It is only comparatively recently that the people of Norway and Sweden have awakened to the possibilities of their countries as winter lands for the seekers of health and sport. The opening up of Switzerland as a popular winter resort has perhaps been the most definite influence in arousing the business instincts of Scandinavians. It must also be admitted that the people of these lands themselves are, generally speaking, only just beginning to recognise their winter privileges and opportunities. Thus winter sports are now being organised and followed with an enthusiasm which comes with the force of a new discovery. The children of to-day are entering into the open-air winter pursuits in a manner hardly dreamt of by their parents. In the same way the establishment of winter health stations is comparatively a new enterprise. It is therefore not to be expected that the needs and desires of foreign visitors can have received as yet full consideration. But having once realised the value of the inheritance there is every reason to believe that Scandinavia will not only considerably extend its health stations for its own peoples but will attract winter visitors from England and other parts of Europe.

Winter Routes to Scandinavia.

Although Norway and Sweden are not so far distant as is popularly supposed, it must be admitted at once that the methods of access are not always as easy as could be desired. In this respect Scandinavia is, and must remain, so far as English visitors are concerned, at a considerable disadvantage as compared with Switzerland. The North Sea intervenes, and this sea is a peculiarly uncertain one, for while the smoothest passage of the year may be in midwinter its waters are readily troubled. Still, all things considered, I am of opinion that for the majority the best route, at least to Norway, is by Messrs. Thos. Wilson, Son, and Co.'s steamers from Hull to Christiania. The Great Northern and North-Eastern Railways run a through coach from King's Cross Station to Hull. During the winter months the steamer leaves the Hull docks on Friday night. The dining-car express leaving King's Cross at 5.45 P.M. should be taken, thus allowing of a comfortable meal before going on board. Your Commissioner, in his tour of investigation, considered it desirable to test the North Sea passage, and crossed by the *Oslo* and returned in the *Montebello*, both excellent boats, comfortable, well furnished, with electric light, hot and cold baths, suitably heated, and admirably staffed. For a patient or health seeker who is a good sailor this route is the most direct, the least tedious, and certainly the healthiest, and, moreover, it has the advantage of being the cheapest.[1]

Visitors to Sweden may travel by steam to Gothenburg by ships of the English Wilson line or the Swedish Thule line. Those wishing to go directly to Stockholm will probably travel by one of the so-called overland routes.[2] For invalids the changes entailed and the over-heating—according to English ideas—of Scandinavian railway carriages are serious drawbacks.

In both Norway and Sweden excellent tourist associations have been formed, the former with a central office in Christiania, and the latter with headquarters in Stockholm. These issue many informing publications and are always ready to afford help to prospective visitors. I desire to take this opportunity of acknowledging my indebtedness to Mr. H. Malling of the "Norwegian Tourist Traffic Association"[3] and Mr. V. Langlet of the "Swedish Tourist Association"[4] for much information and assistance most willingly rendered. But while these central bodies, although somewhat limited by means, are doing much to collect, collate, and distribute material relating to health and sports stations in their respective countries,[5] it must be noted that hitherto comparatively few of the individual sanatoriums and health resorts have even issued prospectuses in English. Some, however, prepare German editions. Until directors of these establishments understand the necessity for a presentation of their claims in English I fear our insular and non-linguistic countrymen will be slow to perceive what the are missing.

The new line between Bergen and Christiania will ha such an influence in the opening up of Scandinavia, ar especially Norway, that its importance can hardly be ove estimated. Along the course of this highway are man centres which doubtless will be quickly developed in summer resorts, and not a few should be well adapted fo winter stations. I had hoped to have been able fully t explore this line, but at the time of my visit the way wa blocked by snow, and although elaborate preparations ha been made for such contingency it would seem that man more snow shelters and tunnels will have to be erected. A quick direct service to Bergen from English and Scottis ports will make some of the finest districts of Norway readil accessible to British visitors. The railway opens up some o the most beautiful parts of the fjords of Western Norway the charming Hallingdal, and mountain plateaux where ski-ing may be practised till almost the middle of summer.

Winter Climatic Conditions in Scandinavia.

In selecting a winter health station there is need for discrimination. Norway and Sweden are such extensive countries that considerable variations in climatic conditions necessarily exist and this is true both for summer and winter.

The West Coast of Norway and the southern parts of Sweden, generally speaking, are not specially suited for winter residence and need not be considered here.

The climatic conditions prevailing during the greater part of the winter throughout a considerable portion of the Scandinavian peninsula are almost ideal as regards the conduct of many forms of winter sport which, one and all, are particularly health giving and health preserving. For many cases of pulmonary tuberculosis, especially in the incipient stage, and for those who by inheritance or acquired infirmities are disposed to this disease, certain centres in both Norway and Sweden present advantages equal to, and in some respects surpassing, those enjoyed by the most favoured winter resorts of Switzerland. Reference to Scandinavia as a desirable land for climato-therapy during winter is in most English and American works dealing with climatic stations conspicuous by its absence, or at best extremely meagre and indefinite. It is interesting to note, however, that in the recent authoritative work of Sir Hermann Weber and state the particular anæsthetic under which they arred." (*b*) Dr. Waldo's own statistics are valueless ause he does not specify the anæsthetic used and the total nber of cases of administration. (*c*) Dr. Waldo argues in our of a coroner's inquest in every case of death under esthesia "in order to improve the statistics."

---

[1] Those travelling by this route should communicate with Mr Spaven, passenger manager of Messrs. Thos. Wilson, Son, and Co., Limited, Hull, and reserve an outside cabin some weeks before departure. It is well also to reserve a seat in the dining-car express, which, however, must be vacated at Doncaster and the journey continued in the coach going directly to Hull.

[2] For full particulars concerning the various routes to Norway and Sweden consult Baedeker's Norway, Sweden, and Denmark (London: Dulau and Co., price 8s.); Cook's Tourist's Handbook to Norway (London: Thos. Cook and Son, 1907, price 1s. 6d.); Bennett's Handbook for Travellers in Norway (Christiania: Thos. Bennett and Sons, price 3 kr.); Bradshaw's Through Route to the Chief Cities of the World (London: Henry Blacklock and Co., Limited, price 5s. net); Wroughton's Winter Sports Annual for 1907-8 (London: Simpkin, Marshall, and Co., 1907, price 2s.).

[3] Forening for Reiselivet i Norge, 2 Storthingsgaden, Kristiania.

[4] Svenska Turistföreningen, 2 Norrlandsgatan, Stockholm.

[5] The Norwegian Tourist Traffic Association has issued an English edition of a most useful list of hotels, sanatoriums, and Skyds stations; and the Swedish Tourist Association publishes annually an excellent illustrated directory of sanatoriums, baths, tourist hotels, and other similar institutions ("Hvilo-och Kurorter i Sverge en Öfversikt af Badorter, Luftkurorter, Sanatorier, Turesthotell, Pensionat, Lanthem M. M. utgifven af Svenska Turestföreningen"). A condensed edition should certainly be issued in English.

Now, Sir, I venture to say Mr. Bellamy Gardner shows by this summary that he has failed to grasp the gist of Dr. ldo's article, and I will deal with his points seriatim.

Dr. Waldo complains that the Registrar-General's istics of deaths under anæsthetics are of little use m a statistical point of view "because they do state the particular anæsthetic under which they urred." The total deaths reported for England Wales 1902–06 were 786, but the fact that the drug used was not reported in 204 cases surely justifies Waldo's general proposition that no statistics worthy the ne exist with regard to anæsthetic mortality. Scientific gress, it may be added, depends mainly on increased uracy, and such accuracy is certainly not a distinguishing ture of the study of anæsthesia. From a general survey Dr. Waldo's paper it may be gathered that his objections to Registrar-General's returns are based on the presence of a nber of fallacies in addition to the particular one cited—ely, that of omission of the mention of the drug in-red. Such fallacies include the anæsthetic deaths that ur in private practice, which as a rule never come either official or to public notice. Can Mr. Bellamy Gardner tend that it is *possible* to arrive at any conclusion of entific value unless we have full information of the alities that occur in the administration of anæsthetics in vate practice? In the same way other no less essential ta are lacking, such as, for example, the exact method death, nature of operation, stage of anæsthesia at which ath occurred, and "delayed" deaths due to the æsthetic. Until statistics can be produced on a ge scale, including these and other essential data, venture to assert that the "science" of anæsthetics must e little more than mere guesswork at the balance of probbilities.

(*b*) Dr. Waldo's own statistics "are valueless because he does not specify the particular anæsthetic under which hey occurred," and because he does not give the total umber of administrations in the two large charitable stitutions within his district whence the figures are drawn. s a matter of fact, Dr. Waldo points out in so many words at no sound conclusions can be drawn from these institutions, "which are fully abreast of, if not in advance of, the majority of the hospitals of the United Kingdom." In one of the two, he says, there is reason to suppose that many administrations are not noted at all. If this be so in two of the best-equipped and regulated hospitals in London what must happen in smaller institutions in the rest of the kingdom and from what precise field does Mr. Bellamy Gardner gather the evidence for the formation of his own opinion? He asks if Dr. Waldo is in ignorance of the work of the Anæsthetics Committee of 1900 which investigated some 25,920 deaths under anæsthesia. The very passage he quotes from their report bears out to the letter the general contention of *Dr. Waldo* that there are no statistics in existence on this particular subject of any scientific value. The passage quoted by Mr. Bellamy *Gardner runs*:—"From a careful study of the whole facts at their disposal the subcommittee feel that owing to (1) the large number of factors in the problem; and (2) the personal equation of the numerous recorders it is impossible to arrive at uniformly satisfactory statistics on the several points submitted to their consideration." *In other words*, the subcommittee emphasise the fact that no sound conclusions are possible from the facts at their disposal.

(*c*) Dr. Waldo "argues for a coroner's inquest in every case of death during general anæsthesia in order to improve the statistics." Mr. Bellamy Gardner ventures to think "that a poorer argument than the foregoing never was put forward upon a matter of importance." I fail to gather the existence of any such argument from a careful perusal of the original article. Mr. *Bellamy Gardner* may be somewhat reassured as to Dr. Waldo's wish to get beyond the dry and arid region of statistics if he reads carefully conclusions 5 and 6 *of the* article in question and considers all that is therein connoted; the conclusions are: "5. *That* with such imperfect data it is impossible to form any trustworthy conclusions as to the absolute ratio of fatalities to administrations, or to the relative proportion of deaths to administrations in the case of particular anæsthetic drugs." "6. That it is highly desirable to arrive at satisfactory conclusions as to the precise facts of all deaths under anæsthesia both for the safety of the public and the furtherance of scientific knowledge."

Other points raised in Mr. Bellamy Gardner's letter I leave to be dealt with by those who have the necessary special knowledge and experience. Those to which I have adverted appear to be well within the intellectual province of the average medical man.—I am, Sir, yours faithfully,

Bryanston-street, W., April 13th, 1908. DAVID WALSH.

ON THE TREATMENT OF SMALL-POX BY LARGE DOSES OF MERCURY WITH CHALK.

To the Editor of THE LANCET.

SIR,—Syphilis is an infectious fever; Dr. W. Moxon called it "a fever diluted by time." Of all the fevers small-pox most closely resembles syphilis, especially in its acute secondary form. The acuteness of secondary syphilis, I believe, can only be appreciated after one has seen that *disease* in India; the treatment here, in consequence, has to be correspondingly vigorous; five grains of mercury with chalk three times a day has very little immediate effect, but ten grains three times a day removes all obvious signs of the skin eruption in from three to six days. In fact, mercury appears to act towards syphilis as quinine does to malaria, a certain sufficient *dosage* being necessary to abate the disease, and until this dose has been reached very little immediate relief is given.

In view of the discovery of the spirochæta pallida the necessity of administering a certain quantity of mercury before the disease can be allayed is now readily appreciated. The striking resemblance between acute secondary syphilis and small-pox *suggested the employment* of mercury in the treatment of the latter complaint also. Experience with syphilis showed that 30 grains of mercury with chalk per day for seven consecutive days produced no diarrhœa or symptoms of poisoning but, on the contrary, gave such marked relief that I decided to employ the same dosage also for small-pox. The results have proved so very satisfactory that I have been *tempted to describe them, although* my conclusions are drawn from the observation of only eight cases. Of the eight cases three had been vaccinated and five had not. Seven were adult men and one was a boy aged 12 years. All were natives of Oudh.

The first case was that of a boy, aged 12 years; he was sent from a mission school on the first sign of the disease. His face, arms, and legs were thickly covered with typical small-pox papules, which were present also on his scalp and the palms of his feet and hands. On the face the papules were so closely situated as to be almost contiguous. No vaccination marks were present; the *case would be described as a severe one.* He was removed to the small-pox hospital (Lucknow) and given five grains of mercury with chalk three times a day *for six days, then* twice a day for the next four days, and once a day for the next three days. Sweet oil was used to soften the skin. The diet consisted of four pints of milk a day. The course of the disease turned out to be very mild, though from the first appearances it threatened to be *very severe*. The temperature never rose above 103° F. and the papules did not suppurate and break down. There was no diarrhœa or sign of mercurialism. On discharge, six weeks after admission, there were no scars, merely the usual pigmented patches seen in natives. The desquamation of the palms and soles was rather tedious. The remaining seven (six were sepoys and followers) were typical cases of small-pox, all were more than moderately severe, and all were seen *very early*. The treatment in all seven consisted of 10 grains of mercury with *chalk three times a day* for six days, then twice a day for four days, and once a day for four more days, 14 days in all. Sweet oil was used to soften the *skin; no other medicine* was given. The diet consisted of four pints of milk per day, and in addition four ounces of arrowroot and two of sugar *when the temperature* reached normal. There was never any sign of mercury poisoning and no diarrhœa. The mercury seemed to have a marked influence *in lowering* the temperature and in modifying the course and subsequent fate of the papules in that no active suppuration occurred and the disease was both cut short and simplified, leaving the available and where mountain torrents provide power at a *minimum* of expense for the production of electric light, &c.

Conditions of Life and Facilities for Travel.

It must be admitted that the health seeker requires much more than natural features of climate and landscape. It is necessary to consider carefully whether other conditions of life are likely to be suited to the requirements of the English visitor healthy or sick. To the luxury-loving and extravagant invalid Scandinavia is hardly likely to appeal. But for the majority of vigorous sport-loving Britishers its winter charms will be irresistible. And for the middle-class patient, especially if he is interested in educational and social work, the sanatoriums of Scandinavia offer opportunities for physical restoration and mental enjoyment at a price within his means. The character of food and order of meals, the customs and usages, the domestic arrangements, and general life of the people are all such as are likely to interest and to be acceptable to the average Englishman. The excellence, variety, and richness of much of the food are certainly points of importance for the invalid. Cream enters into the composition of the majority of the dishes and for consumptive and tuberculously disposed cases is undoubtedly generally very advantageous. Unfortunately in all districts houses and railway carriages are much over-heated, and double doors and windows clearly indicate that there is need for a practical exposition of open-air methods. But such matters can usually be adjusted to individual requirements by a little tact and judicious arrangement.

The Norwegian is the Scotchman, the Swede the Frenchman, of Scandinavia. Christiania reminds one of Edinburgh, and Stockholm is the acknowledged "Paris of the North." Scandinavians are, generally speaking, highly educated, progressive in thought and action, democratic in State affairs, courteous and hospitable, and ready to extend a real welcome to English visitors. Relationships between our own King and Queen and the Royal houses of Norway and Sweden afford a very real link binding the Scandinavian people and our own country; and there is also a true kinship in sentiment and sympathy. It may also be noted that in great measure their point of view may be said to be our point of view. The visitor will, however, do well to remember that the events leading up to, and culminating in, the separation of Norway from Sweden are not sufficiently far removed to make it wise or desirable to discuss the matter with those to whom it has been of momentous importance.

The members of the medical profession in both Norway and Sweden, by their long training, careful supervision, and strictly regulated examinations, rank probably among the best qualified of European practitioners, and English medical practitioners need feel no doubt about placing their patients under the care of their Scandinavian *confrères*.

A note may be added respecting railway travel in winter in Norway and Sweden. This, although comparatively slow, is thoroughly comfortable and the arrangements made whereby trains stop at certain stations to allow travellers the comfort of well-cooked but inexpensive meals are particularly admirable.[7]

The non-linguistic Englishman need have no hesitation about not being understood. English is taught in practically all the schools; and in all the important hotels, sanatoriums, and establishments catering for English visitors English is spoken. Most of the Norwegian and Swedish physicians with whom I was in consultation spoke fairly good English, although it must be admitted that they generally stated that their German was better. In the public schools German is usually commenced some two years before English is studied. In the universities German text-books seem to be chiefly used and medical and other monographs appealing to the outside world are usually printed in Germany. Co-education of the sexes prevails more or less throughout Scandinavia and certainly appears to be altogether advantageous, as judged both by the home life and in the conduct of the more public avocations.

Scandinavian Sanatoriums and Health Stations for Winter Residence by English Visitors.

The term "sanatorium" in both Norway and Sweden is used in a much broader sense than that in which we are accustomed to employ it at home. It is used to include what we should designate hydropathic establishments, mountain health resorts, and country hotels. Most of these are not intended for cases of serious illness. Some seek to attract those requiring recuperation for body and recreation of mind, convalescents, the overworked, neurasthenics, and subjects standing in need of a simple rest cure, quiet and gentle exercise in a salubrious and picturesque district. Others have more or less elaborate equipment for simple and medicinal baths and take chronic cases of rheumatism, cardiac derangement, anæmia, and the like. In Sweden excellent arrangements have been made at some places for the employment of mechanical treatments, massage, physical exercises, and medical gymnastics for skill in which the Swedes have justly won world-wide distinction. Not a few of the mountain sanatoriums and country resorts are little more than sports centres. All these "sanatoriums" exclude consumptives. There are, however, sanatoriums for consumptives and other tuberculous cases, chiefly intended, it is true, for local needs, but to which in some cases English patients might be sent with advantage.

The Scandinavian "sanatoriums" may be conveniently classified thus: 1. Private sanatoriums for consumptives. 2. Public sanatoriums for consumptives. 3. Public marine sanatoriums for tuberculous children. 4. Sanatoriums which are health stations for non-tuberculous visitors: (*a*) with resident medical director; and (*b*) without resident physician. 5. Country and mountain sanatoriums (*a*) open all the year round and (*b*) open during certain seasons. 6. Marine sanatoriums, usually open only during the summer. With these last we have at present no concern. In addition to the above there are a number of sports club houses, tourist hotels, and skyds stations, which young and vigorous persons of both sexes frequent in the winter months and particularly during the Easter holidays.

Your Commissioner is of opinion that at present in the selection of a centre suited to the requirements of the majority of English visitors seeking health and rest in winter two important points should be kept in mind: (1) convenience of access and (2) proximity to an important town. Judged by these considerations the most suitable winter stations in Norway may be looked for in the neighbourhood of Christiania and Trondhjem, and in the south-eastern and eastern country districts in Valdres, Gausdal, and Gudbrandsdal and their neighbourhoods. With the opening up of new lines of railway other desirable centres will be rendered accessible.

In Sweden at the present time English visitors will probably be inclined to make their winter centres near Stockholm at such a resort as Saltsjöbaden, or at Hindas or Hultafors on the Gothenburg-Böras line and readily accessible from Gothenburg. In the near future there promises to be a large addition to first-class winter resorts in Sweden.

In subsequent articles it is proposed to deal in detail with some of the more important Scandinavian health stations.

THE BATTLE OF THE CLUBS.

(From our Special Commissioner.)

The Struggle against the Coventry Provident Dispensary.—Formation of a New Dispensary Service.—Result after Nine Months.—Disciplinary Sanctions.—Effect of the Dispute on Hospital Abuse.

Coventry, April 13th, 1908.

The struggle between the medical profession and the Coventry Provident Dispensary has passed through the acute and has now reached the chronic stage. Nothing very startling is likely to occur but a long and patient tussle between the two parties will probably continue for some years to come. More than ten years ago the points at issue were fully described.[1] The abuses were then acknowledged by the medical staff in the employ of the dispensary but they failed to see that it was possible to take any effective remedial action. There were many practitioners close by at Birmingham ready to take their places. The majority of the practitioners at Coventry had united together and had even formed an association called the Coventry Public Medical Service, where contract work was organised by the medical men themselves in such a manner ean, close to the spine, infers lymphatic infection beyond nd points to the impossibility of eradicating the disease." here is no indication in Mr. Symonds's paper that any art of any specimen removed has been microscopically xamined. Even in the case where "a gland was nclosed in a ligature and part had to be left" we re led to believe that the gland was malignant with ut being referred to the testimony of the microscope. t the present time there is comparatively little information s to the extent of gland invasion in cases which, from other oints of view, are operable, and it is a matter for regret hen the record of a case affords no information on the icroscopic characters of the glands removed. It is most isleading to look upon the size or even the hardness of a land as proof of malignancy. Glands as large as a bean at e upper end of the ileo-colic chain are not infrequently bserved in cases where there is no suspicion of malignant or ther disease of the bowel. It is well that "experience hows that the presence of such glands need not weigh gainst excision."

---

[1] The chief railways in both Norway and Sweden belong to the State but some few lines are still in the hands of private companies. The traveller should always obtain the current number of the official time tables before arranging a journey.

[1] The Lancet, June 12th (p. 1637) and 19th (p. 1707), 1897.

We have shown[2] that the whole of the ileo-colic chain of lands must be regarded as being primary to the cæcum and ppendix, glands at the extreme upper end of the chain ceiving direct vessels from the bowel and standing in the ime relation to it as those in contact with it. Assuming at by "a gland close to the spine," one of the uppermost embers of this chain is meant and bearing in mind the natomy of the chain, it does not seem to us that an obvious nlargement of such a gland, even if thought to be definitely alignant, should disturb the operator's intention or give rise o more apprehension than a diseased gland of the anterior r posterior ileo-colic groups which would certainly deter no ne from proceeding to excision. Gland disease limited to the leo-colic chain and not involving the great glands around the uperior mesenteric trunk should not forbid excision, other onditions being favourable, nor should the presence or absence of diseased glands determine the extent of the operation. In cases where there is no obvious change in the glands the whole of the chain should be removed, otherwise there is no reasonable certainty of complete removal of possibly infected glands. In cases where the glands are enlarged and possibly malignant there may be less certainty of complete removal. Shortly, we may say that this operation is the least and the most that may be done in carcinoma of the cæcum and ascending colon.—We are, Sir, yours faithfully,

J. F. DOBSON.
School of Medicine, Leeds. J. KAY JAMIESON.

A NOTE ON THE TREATMENT OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Most practitioners are no doubt familiar with the excellent results obtained in severe cases of diphtheria marked by vomiting and cardiac depression by the adoption of Dr. Rolleston's method. This method consists in the administration by the mouth or rectum of a solution of adrenalin chloride with camphor water. In practice, however, it is sometimes inadvisable to give in the condition referred to *anything* by the mouth, and in other cases there may be intolerance of rectal injections.

For nearly two years past I have used at the Mortlake isolation hospital specially prepared tabloids, each containing $\frac{1}{100}$th of a grain of adrenalin chloride and $\frac{1}{100}$th of a grain of sulphate of strychnine, to make solutions for hypodermic injection and I have found this plan answer admirably.* One or two of these tabloids may be administered every two, three, or four hours according to the gravity of the case; the action of the adrenalin appears to be sustained by the strychnine, which, of course, has its own special value in diphtheria, and the treatment can be continued and carried to a happy issue when neither mouth nor rectal administration is possible.

The method is of service even in cases admitted in a desperate condition, but its greatest value, I think, is displayed when the administration of the two drugs is commenced immediately that vomiting or cardiac irregularity is noticed. We make it a part of the daily routine that immediately on the occurrence of vomiting all food, medicine, and throat treatment are stopped and adrenalin and strychnine be at once given hypodermically.

Some account of this treatment was given in a paper published in the *West London Medical Journal* for July, 1907, but a year's increased experience has amply confirmed my opinion of its usefulness.

I am, Sir, yours faithfully,
F. G. CROOKSHANK, M.D. Lond.,
Barnes, S.W., April 18th, 1908. Medical Officer of Health.

THE CONGENITAL PIGMENTATION OF MONGOLIANS.

To the Editor of THE LANCET.

SIR,—A curious condition has been brought to my notice by a very observant midwife: it is that every full-caste Chinese baby is born with a large-sized ecchymosis or bluish-black staining on each buttock in the centre of which is a still blacker spot. On the baby with which I had the chance of observing this strange mark the centre of intense colouration was on one side only, but both buttocks had a distinctly circumscribed bluish-black discolouration beneath the skin. I have examined other Chinese children and have found bluish-black areas up to the age of two years; in one baby six months of age it had already disappeared, but the father assured me it was there when it was born and also in all his children; in some families the spots were mostly situated high up on the sacrum.

I have seen a Japanese baby three months of age, but I cannot say that I found the discolouration except a slight stain on the sacrum, but even amongst them it is a well-known and looked-for sign, and its absence in the newly born is the cause of some amusement; they seem to know the white child does not possess this distinctive sign at birth.

I do not know if this peculiarity has been commented upon before. As the Chinese are intensely exclusive in matters connected with attendance on their women at child-birth it is the exception for a male doctor to be present. It was further stated by the midwife that she had observed it in the half-caste Chinese children but, curious to remark, on only one buttock, inferring that its incompleteness was indicative of Chinese intercourse with European women.

I am, Sir, yours faithfully,
EDWARD P. LEAVY, L.R.C.P. & S., L.M. Irel.,
Government Medical Officer, Geraldton.
Geraldton, Johnstone River, Queensland, Feb. 10th, 1908.

⁂ We publish on p. 1223 of this issue a brief annotation on Mr. Leavy's communication.—ED. L.

MEMORIAL TO THE LATE PROFESSOR ANNANDALE, PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

To the Editor of THE LANCET.

SIR,—Many friends and former pupils of the late Professor Annandale, in the belief that a scheme for establishing a memorial to perpetuate his name would be received with general approval, are taking steps towards its accomplishment. For this purpose a large and influential general committee has been formed, also a small executive committee.

It is proposed that a fund should be raised for the purpose of awarding a gold medal annually to the best student in clinical surgery at the final examination to be known as "The Annandale Gold Medal in Clinical Surgery." In addition to this it is thought that a bust of the late Professor should be placed in the lecture theatre of the Royal Infirmary, Edinburgh, so long associated with his teaching. As the late Professor Annandale identified himself so closely and for so many years with the athletic life of the University it has been suggested that if there should be any surplus after providing for these objects it might be devoted to some memorial in connexion with the athletic club.

The committee have appointed Mr. H. M. D. Watson, C.A., 13, Rutland-square, Edinburgh, to act as their secretary and treasurer, and those who desire to subscribe are requested to communicate with him as soon as possible, as it is thought important to carry through the scheme without delay.

Yours faithfully,
WM. TURNER,
Principal of the University of Edinburgh.
J. M. COTTERILL,
President of the Royal College of Surgeons Edinburgh.
H. M. D. WATSON,
Edinburgh, April, 1908. Secretary and Treasurer.

---

[2] THE LANCET, April 27th, 1907, p. 1137.

arrears of payments, the medical staff would receive as net benefit two-thirds of the subscription. In other words, as matters now stand and when every subscription due is paid, the working expenses for the last quarter will not exceed one-third of the receipts. Further, the receipts during this last quarter, which is the third quarter during which the new dispensary service has been in existence, are the largest yet gathered in. Consequently the new institution is making progress. Nevertheless, the medical officers have lost several hundred pounds a year, and it is urged that a fund should be in existence to help the weaker members of the profession who are not in a position to make such sacrifices. But, of course, the time to create a fund of this description is when there is no struggle; it should be accumulated beforehand. To-day every new subscriber who comes in or who leaves the old Provident Dispensary to join the new dispensary service yields a larger profit than his predecessors because the initial expense is now covered. In the new service the patients all call at the surgeries of their medical officers, while in the old Provident Dispensary they have to go to the building belonging to that institution and have to wait there as at the out-patients' room of a hospital. After they have seen their medical officer the drugs are dispensed in the same premises. The new service has found it expedient to establish a dispensary of its own, for which each of the four medical officers had to subscribe £25. It employs a qualified dispenser, buys its own drugs, and is thus better able to control them, and they cost less. Now, if it had more patients this would occasion no further outlay in rent and salaries and the only extra cost would be the time given to them and the drugs which they would actually consume. Thus, it is thought that now that the initial expense and the salaries have been met a thousand more subscribers would only cost about £30 or £40 a year, while they would bring in £266. The number of subscribers is likely to increase, as little by little the public learn better to appreciate the fact that their true interests are identical with those of the medical profession. The real object is to prevent the reduction of medical attendance to a hurried and insufficient examination shortened so as to meet the smallness of the pay rather than the requirements of the patient. That is why the medical profession protests against hospital abuse as well as the abuse of club practice. The struggle with the Coventry Provident Dispensary is calculated to increase the abuse prevalent at the Coventry Hospital. The medical staff of the Coventry Provident Dispensary are not met in consultation by the other local members of the profession. Consequently, several of their patients, when they found that they could not get a second opinion, left the Provident Dispensary. Naturally, and so as to avoid this, such cases will if possible be sent to the hospital and thus the difficulty of not being able to call in a consultant will be avoided by increasing the sum total of hospital abuse.

Some members of the committee of management of the Provident Dispensary are also on the hospital committee of management. This places the hospital medical staff in an awkward position, for they are working under the authority to some extent of men concerned in an institution which is repudiated and condemned by the profession to which they belong. A subcommittee was appointed at the hospital a short time ago to ascertain what abuse existed and how it could be remedied. This committee consists of two medical men, two representatives of the workmen subscribers, and two or three members of the committee of management. The committee met once or twice and then adjourned for a month so that specific cases could be brought before it. This has now been done. Also the division of the British Medical Association passed a resolution bearing on the subject and sent it to the subcommittee. The number of hospital patients is so enormous that one single member of the honorary staff is sometimes expected to see no less than 60 patients in an hour and a half. Then there are some men who have seized the opportunity afforded by the dispute to leave the old Provident Dispensary and not to join the new one, trusting wholoy to the hospital should they fall ill. As the workers' subscriptions to the hospital increase yearly they think that they have a right to walk in and to receive whatever sort of medical treatment they may need. Thus the limit of efficiency of the hospital has long been passed by the excess of patients attending, and the dispute with the Coventry Provident Dispensary can only tend to increase this state of affairs. On the other hand, it is something to know that this latter institution has been hardly hit and that the abuses which it represents cannot continue with impunity. Moreover, the medical practitioners who have inflicted this blow though they have also lost a considerable portion of their income are gradually winning it back. In any case, what they have now is really theirs and will count as an asset when they want to sell their practices, whereas before they could not sell their posts on the Provident Dispensary, for it was not certain that the services of their successors would be accepted by that institution. But better than all these material considerations is the fact that the five medical officers who have made these considerable sacrifices are now acting in full harmony with their profession and hold an honourable position in its ranks.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Territorial Medical Corps (Manchester).

THE Royal Territorial Medical Corps (Manchester) has enlisted about 250 men who have generally joined for one or two years. But the officers of the corps have to enlist 725 men, to provide the staff for a general hospital, which will, according to report, be set up on mobilisation, and sanitary squads. In many respects the new arrangement of the medical service is an expansion of the medical service of the Volunteers. Thus the bearer companies and field hospitals of the Volunteer organisation become consolidated into field ambulances for cavalry and infantry and there are to be three of them for each division of the Territorial Force. New features, however, appear. There will be hospitals, stationary and general, the staffs of which will consist of civil hospital physicians and surgeons who, though "possessing no organic connexion with the divisions, will be raised in the same territorial area should the local staffs of the civil hospitals coöperate for work in time of war in the vicinity of their own civil hospitals." Also during operations for home defence the coöperation of medical men engaged in preventive medicine will be sought. In time of war they are to assist with their advice should troops be massed in the vicinity of their own spheres of work. Professor G. A. Wright has been appointed administrator-in-charge of the general hospital and Mr. W. Thorburn is the registrar and secretary. The unit for this hospital is to be 43 men, and the commanding officer wishes to get some of the Manchester University students and pupil teachers in elementary schools to join. Members of this unit will be required to attend one of the large military hospitals for training for "eight or 14 days in the year, where they will receive instruction in nursing, &c." There has been a cordial response to the call of the authorities by all the principal men on the staffs of the Royal Infirmary, the Ancoats Hospital, and the Salford Hospital to serve the general hospital on mobilisation, as would be expected by those who know them. 99 men are to be enlisted for the sanitary squads whose duty will be to supervise the sanitary arrangements in the field and to look after the water-supply. This fragmentary sketch of the organisation required in constructing even this small portion of the scheme of the army as recently elaborated shows how desirable, or rather how necessary, it is that the business should be put in hand during the days of peace.

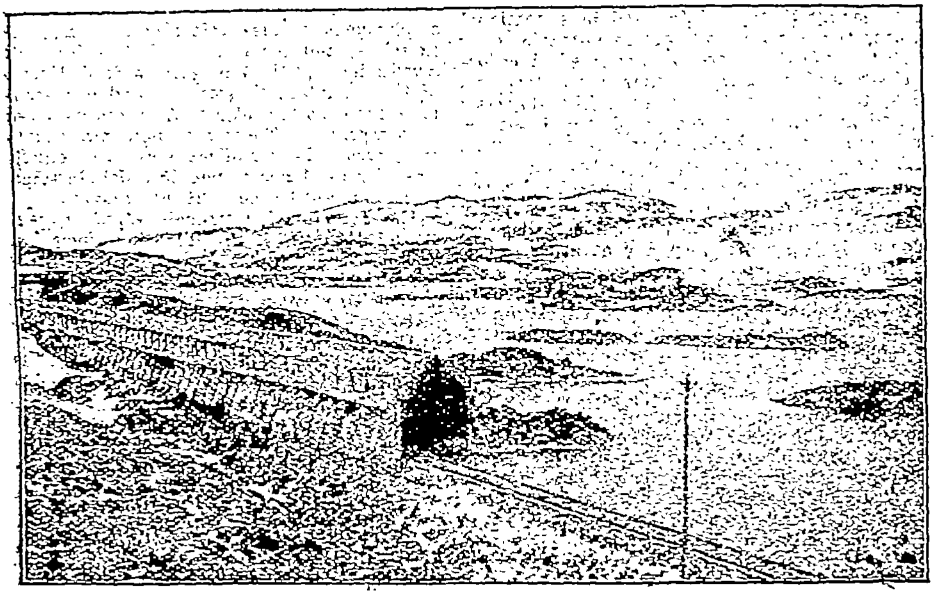
Mersey and Irwell Committee.

The meeting of the Mersey and Irwell committee on April 7th was marked by the resignation of the chairman, Sir John Hibbert, on account of his health. He has held the position for many years. Even if his health had continued good his advanced years would have entitled him to claim relief from public labours. In his letter of resignation he summarises the work that has already been done, and though, when the Mersey and Irwell are looked at or smelled, the purification remaining to be accomplished seems still very great, while the visible and olfactory evidences of noisome filth seem apparently much as they were years ago, it must be acknowledged that the committee has always been at work and that some good has been done. It has sometimes been thought that more energy might have been shown, but, as Sir John Hibbert says, much has been done for carrying out the powers entrusted to it, and "perhaps under the special circumstances of the specially foul state of the streams in the district much may have been left undone. Our motto has been the Latin proverb 'Hasten slowly,' thus giving both manufacturers and local authorities time for carrying

Dr. Parkes Weber* the opinion is expressed that the climatic state of the mountainous regions of Norway "can exert a bracing effect on invalids and healthy persons equal to that produced by climates of considerably higher altitude in the Swiss Alps." This seems to be undoubtedly the case and is indeed for many cases an advantage of no little importance.

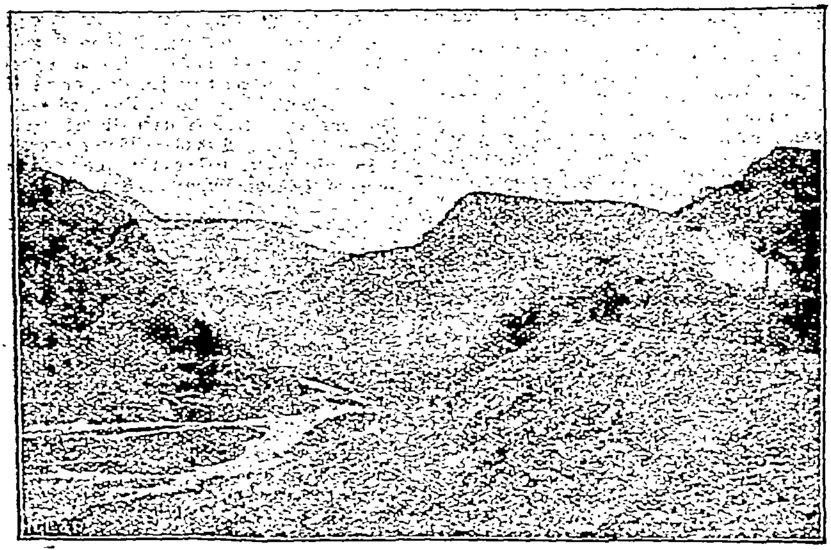
Norway is distinctly a mountainous country, having a mean altitude of about 1500 feet. It consists mainly of deep fjord-cut mountains, elevated mountain plateaux and valleys, extensive forests, and comparatively small areas of cultivated land. Its towns are small and its homesteads are widely scattered. From North to South its extent is 1100 miles, while its breadth varies from seven to 280 miles.

FIG. 1.



Snow tunnel on the new Bergen to Christiania Railway, 4260 feet above sea level.

FIG. 2.



View in the course of the new Bergen to Christiania Railway.

Sweden is a more extensive country. It is over 1000 miles long and has an area of 172,876 square miles. Whilst comparatively flat in its greater extent it is rich in lakes and rivers and in certain districts, particularly the far-extending Norrland, offers unlimited opportunities for the winter sportsman.

In both countries there can be found practically all the natural conditions desirable for a winter sanatorium, such as pure, rarefied, dry, dust-free, and bracing air, much sunlight, absence of irritating fogs, little wind, and moderate altitude. The snow-covered ground secures an absence of dust, a reflecting medium for the sun's rays, and a surface which lends itself to numerous forms of health-giving exercise. Snow does not fall frequently but usually comes at more or less definite times.

It should also be noted that the sanatoriums are often situated in forest regions where timber for construction is arrears of payments, the medical staff would receive as net benefit two-thirds of the subscription. In other words, as matters now stand and when every subscription due is paid, the working expenses for the last quarter will not exceed one-third of the receipts. Further, the receipts during this last quarter, which is the third quarter during which the new dispensary service has been in existence, are the largest yet gathered in. Consequently the new institution is making progress. Nevertheless, the medical officers have lost several hundred pounds a year, and it is urged that a fund should be in existence to help the weaker members of the profession who are not in a position to make such sacrifices. But, of course, the time to create a fund of this description is when there is no struggle; it should be accumulated beforehand. To-day every new subscriber who comes in or who leaves the old Provident Dispensary to join the new dispensary service yields a larger profit than his predecessors because the initial expense is now covered. In the new service the patients all call at the surgeries of their medical officers, while in the old Provident Dispensary they have to go to the building belonging to that institution and have to wait there as at the out-patients' room of a hospital. After they have seen their medical officer the drugs are dispensed in the same premises. The new service has found it expedient to establish a dispensary of its own, for which each of the four medical officers had to subscribe £25. It employs a qualified dispenser, buys its own drugs, and is thus better able to control them, and they cost less. Now, if it had more patients this would occasion no further outlay in rent and salaries and the only extra cost would be the time given to them and the drugs which they would actually consume. Thus, it is thought that now that the initial expense and the salaries have been met a thousand more subscribers would only cost about £30 or £40 a year, while they would bring in £266. The number of subscribers is likely to increase, as little by little the public learn better to appreciate the fact that their true interests are identical with those of the medical profession. The real object is to prevent the reduction of medical attendance to a hurried and insufficient examination shortened so as to meet the smallness of the pay rather than the requirements of the patient. That is why the medical profession protests against hospital abuse as well as the abuse of club practice. The struggle with the Coventry Provident Dispensary is calculated to increase the abuse prevalent at the Coventry Hospital. The medical staff of the Coventry Provident Dispensary are not met in consultation by the other local members of the profession. Consequently, several of their patients, when they found that they could not get a second opinion, left the Provident Dispensary. Naturally, and so as to avoid this, such cases will if possible be sent to the hospital and thus the difficulty of not being able to call in a consultant will be avoided by increasing the sum total of hospital abuse.

* "Climatology and Balneology," by Sir Hermann Weber, M.D., F.R.C.P., and F. Parkes Weber, M.D., F.R.C.P., p. 184 (London, 1907.)

Some members of the committee of management of the Provident Dispensary are also on the hospital committee of management. This places the hospital medical staff in an awkward position, for they are working under the authority to some extent of men concerned in an institution which is repudiated and condemned by the profession to which they belong. A subcommittee was appointed at the hospital a short time ago to ascertain what abuse existed and how it could be remedied. This committee consists of two medical men, two representatives of the workmen subscribers, and two or three members of the committee of management. The committee met once or twice and then adjourned for a month so that specific cases could be brought before it. This has now been done. Also the division of the British Medical Association passed a resolution bearing on the subject and sent it to the subcommittee. The number of hospital patients is so enormous that one single member of the honorary staff is sometimes expected to see no less than 60 patients in an hour and a half. Then there are some men who have seized the opportunity afforded by the dispute to leave the old Provident Dispensary and not to join the new one, trusting wholely to the hospital should they fall ill. As the workers' subscriptions to the hospital increase yearly they think that they have a right to walk in and to receive whatever sort of medical treatment they may need. Thus the limit of efficiency of the hospital has long been passed by the excess of patients attending, and the dispute with the Coventry Provident Dispensary can only tend to increase this state of affairs. On the other hand, it is something to know that this latter institution has been hardly hit and that the abuses which it represents cannot continue with impunity. Moreover, the medical practitioners who have inflicted this blow though they have also lost a considerable portion of their income are gradually winning it back. In any case, what they have now is really theirs and will count as an asset when they want to sell their practices, whereas before they could not sell their posts on the Provident Dispensary, for it was not certain that the services of their successors would be accepted by that institution. But better than all these material considerations is the fact that the five medical officers who have made these considerable sacrifices are now acting in full harmony with their profession and hold an honourable position in its ranks.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Territorial Medical Corps (Manchester).

THE Royal Territorial Medical Corps (Manchester) has enlisted about 250 men who have generally joined for one or two years. But the officers of the corps have to enlist 725 men, to provide the staff for a general hospital, which will, according to report, be set up on mobilisation, and sanitary squads. In many respects the new arrangement of the medical service is an expansion of the medical service of the Volunteers. Thus the bearer companies and field hospitals of the Volunteer organisation become consolidated into field ambulances for cavalry and infantry and there are to be three of them for each division of the Territorial Force. New features, however, appear. There will be hospitals, stationary and general, the staffs of which will consist of civil hospital physicians and surgeons who, though "possessing no organic connexion with the divisions, will be raised in the same territorial area should the local staffs of the civil hospitals coöperate for work in time of war in the vicinity of their own civil hospitals." Also during operations for home defence the coöperation of medical men engaged in preventive medicine will be sought. In time of war they are to assist with their advice should troops be massed in the vicinity of their own spheres of work. Professor G. A. Wright has been appointed administrator-in-charge of the general hospital and Mr. W. Thorburn is the registrar and secretary. The unit for this hospital is to be 43 men, and the commanding officer wishes to get some of the Manchester University students and pupil teachers in elementary schools to join. Members of this unit will be required to attend one of the large military hospitals for training for "eight or 14 days in the year, where they will receive instruction in nursing, &c." There has been a cordial response to the call of the authorities by all the principal men on the staffs of the Royal Infirmary, the Ancoats Hospital, and the Salford Hospital to serve the general hospital on mobilisation, as would be expected by those who know them. 99 men are to be enlisted for the sanitary squads whose duty will be to supervise the sanitary arrangements in the field and to look after the water-supply. This fragmentary sketch of the organisation required in constructing even this small portion of the scheme of the army as recently elaborated shows how desirable, or rather how necessary, it is that the business should be put in hand during the days of peace.

Mersey and Irwell Committee.

The meeting of the Mersey and Irwell committee on April 7th was marked by the resignation of the chairman, Sir John Hibbert, on account of his health. He has held the position for many years. Even if his health had continued good his advanced years would have entitled him to claim relief from public labours. In his letter of resignation he summarises the work that has already been done, and though, when the Mersey and Irwell are looked at or smelled, the purification remaining to be accomplished seems still very great, while the visible and olfactory evidences of noisome filth seem apparently much as they were years ago, it must be acknowledged that the committee has always been at work and that some good has been done. It has sometimes been thought that more energy might have been shown, but, as Sir John Hibbert says, much has been done for carrying out the powers entrusted to it, and "perhaps under the special circumstances of the specially foul state of the streams in the district much may have been left undone. Our motto has been the Latin proverb 'Hasten slowly,' thus giving both manufacturers and local authorities time for carrying that no abuse could arise, and they complained that the medical officers in the service of the Coventry Provident Dispensary would not join them. The latter retorted that if they did they would lose some £2000 annual income without any sort of compensation or even the hope of putting an end to the abuses which existed. Later, however, when the British Medical Association took the matter up, the medical officers of the dispensary felt less isolated. They began to look forward to some outside support but they certainly missed the psychological moment at which they should have taken action. When the local division of the British Medical Association decided not to consult with the medical officers of the Coventry Provident Dispensary they should then and there have made their stand. Instead of this a year was lost in negotiations and attempts to effect a compromise. At last one of the dispensary medical officers had a dispute with the committee of management and his precipitated matters. As already related, five members of the dispensary medical staff resigned and ceased to work for that institution on June 25th last. Being compelled to give three months' notice the dispensary had time o obtain the services of three outsiders. One of these newcomers has displayed great energy and has acquired a certain popularity. Further, he took the bull by the horns and instead of waiting to be attacked for his action in helping to break the strike he actually attempted to prosecute the medical officers of the dispensary who had resigned. The case is described in full in the supplement of the *British Medical Journal* of Dec. 7th, 1907. The officers who had resigned were accused of sending a canvasser around to tout for patients. Of course, the accusation could not be maintained.

When the five members of the Coventry Provident Dispensary resigned they agreed to start a new dispensary service. Certainly it would have been better had they thrown in their lot with the organisation formed years ago by the majority of the Coventry practitioners precisely for the purpose of putting an end to the abuses connected with contract practice. However, this was thought to be too great a change, more than could be expected all at once, though perhaps it may ultimately be brought about. Nor could the local practitioners energetically urge such a course, because it might appear as if they were arguing in their own interests. Indeed, so great was their anxiety to avoid any such suspicion that the members of the Coventry Public Medical Service decided to refuse to accept any patients who had been attended by the five officers of the Provident Dispensary. Thus it cannot be said that they helped to produce the dispute in the hope of reaping some personal advantage. Though the rules of the new organisation are not so good as their own they are a great improvement on the Old Provident Dispensary. Thus the Coventry Public Medical Service has a wage limit of 30*s.* a week, and no medical officer can have more than 3000 subscribers on his books; the limit used to be 2000 but was extended in the hope of inducing practitioners to give up their private clubs. The new dispensary service has a £2 per week wage limit and no limit as to the number of subscribers on any one practitioner's books. This latter is a serious flaw, for it is impossible to do justice to a very large number of patients. Again, the Coventry Public Medical Service is open to all fully qualified medical practitioners, whereas to join the new organisation it is necessary to be elected by a two-thirds majority. One good point is that the new dispensary service is not managed wholly by its members but one member of the local division of the British Medical Association is added to them so that the general interests of the profession will be represented. Then there is a rule debarring any medical practitioner who has commenced practice in Coventry without an introduction from being elected for four years. Also, any member found guilty of infamous conduct in the professional sense can be expelled by a two-thirds majority.

Subscribers are enrolled in the new dispensary service whose yearly incomes do not average more than £2 a week, and he or she must pay 1*d.* per week. Persons over 60 years of age have to pay 10*s.* entrance fee and a collector is to call once a month for the money. Illnesses caused by drunkenness or immorality are not included in the treatment given. For confinements the charge to members is 1 guinea and a midwife's charge is 10*s.* Such are the rules of the new service which four out of the five medical officers of the old Provident Dispensary formed. The fifth lives so far away that it is not thought practicable for him to participate and those subscribers to the old dispensary who left when he left enrolled themselves in the personal, private club which he has established. When all this was arranged a collector was engaged at a fixed salary so that he has no interest in persuading people to join, that is to tout. Yet this is the man who was accused of touting. What he did was to call on all the patients of the four medical officers who had resigned their posts on the Provident Dispensary and to inform the patients that if they desired to continue to consult their usual medical adviser they could only do this by joining the new dispensary service. The collector did not call on any one who was not already on the books of the medical practitioner in whose name he spoke.

There is, of course, a good deal of dissatisfaction caused by the mere fact that an accusation against the very men whom the British Medical Association and all the profession were pledged to support was allowed to pass by the penal committee. Yet the four medical officers who had resigned were summoned to appear before the General Medical Council, only to be told when they got there that the charge against them had been withdrawn. On the other hand, if the British Medical Association takes action against medical practitioners who are considered to have acted in a reprehensible manner it cannot even publish the fact. Thus it appears that among the medical men who in various parts of the country have taken service for such condemned institutions as the Coventry Provident Dispensary there are some who belonged to the British Medical Association. Consequently they have been expelled from the Association and there is a regular form notifying such expulsions and yet these have not been used. There is, it appears, no rule in regard to publishing the fact that a member of the Association has been expelled, therefore the Association has, I understand, been informed by its legal advisers that it would not be wise to publish the names of the members who have been expelled. In these circumstances I would recommend the British Medical Association to study the Statutes of the French Medical Syndicates. These French medical associations can not only publish a full record of what they do, but they can punish as well as expel their members if these do not observe faithfully the principles laid down in the deed of association. The punishment consists of a fine of from 16*s.* to £20 and the civil tribunals, when it is necessary to appeal to them, confirm and enforce the sentence pronounced by the medical jury of the medical union. Therefore, if this law applied to the British Medical Association any member of that body taking service under the Coventry Provident Dispensary or other similar institution could not only be publicly expelled but could be fined £20. Obviously there is great need of disciplinary sanctions in the medical profession of Great Britain.

Nevertheless, some progress is made, though the cause at Coventry received a great blow in the sudden death of Dr. T. A. Hird. This gentleman was the most popular of all the medical officers formerly attached to the Coventry Provident Dispensary and had far the greatest number of subscribers on his books. A very large proportion of them would have desired to follow him when he left the Provident Dispensary, but he died on the very eve of the day when he had to appear before the General Medical Council to answer the charge mentioned above. By means of a locum-tenent an attempt has been made to carry on the practice and his son was fully qualified a week or two ago. Nevertheless, the following would, of course, have been greater but for this most untimely death. As it is, however, about 8000 members have left the old Provident Dispensary and joined the new dispensary service. The success of the movement would have been greater still had there been a relief fund to fall back upon, for a sixth member of the Provident Dispensary's staff was willing to join the strike if a sum of £200 a year could be guaranteed, as he was too old to begin life over again. Offers were made and the sum of about £100 was forthcoming. 40 local practitioners would have subscribed on an average £2 a year, so as to draw one more medical officer away from the staff of the Provident Dispensary, and this fact alone suffices to show how that institution is considered by the profession; then a small sum could have been obtained from the British Medical Association, but it was quite impossible to raise £200 a year; therefore only five medical officers left the dispensary, though a sixth would have done so had he been younger and better able to support himself.

With the members who have left the Provident Dispensary and joined the new dispensary service, if there were no the county and are not confined to one district. There would seem to be room here for a very useful investigation on the question as to whether any relation *does*, in fact, exist between the use of "cake" and isolated cases of anthrax. The Board, in a memorandum which is frequently circulated, offers to make an examination of food-stuffs where suspicion can be definitely traced to "cake" or other food as the cause of the disease. This is difficult to establish in any particular case, but by collecting information as to the use of "cake" on farms where cases of anthrax have occurred it would seem profitable, if *prima-facie* evidence were found to incriminate "cake," to inquire into the circumstances of the manufacture and methods of transport of "cake."

Sanitary Committee of the Newcastle Corporation.

The estimates of expenditure for the year ending March 31st, 1909, submitted by the sanitary committee to the city council totalled £51,020. The expenditure on rate account is estimated at £32,512, against £27,338 for 1907–08 and £26,383 for 1906–07. The estimated increase of expenditure over 1907–08 is therefore £5174, against an increase of £955 in 1907–08 as compared with 1906–07. Of this total increase of £5174 rather more than two-thirds, £3462, is absorbed by the increase in cost of the city isolation hospitals and is accounted for by the fact that at Walker Gate Hospital accommodation for an additional 74 beds over and above 105 at present in use has been provided, and it is hoped that this further accommodation will be almost immediately available for the reception of patients. It was not surprising, therefore, that the discussion on the estimates was chiefly directed to criticism of the cost of hospital administration. The estimates had already been severely handled in committee—in fact, consideration of the estimates had been adjourned four times on the initiative of Alderman Flowers "in order that they might go carefully into them, to see whether they could reduce them," and the result of this prolonged deliberation was that Alderman Flowers was able at the meeting of the council warmly to defend the estimates. During the course of the discussion in the council comparison was made between the relative cost of maintaining the workhouse infirmary and the infectious diseases hospitals, and it was shown that the cost of administration of the latter, where only infectious diseases were admitted, was not very much greater than the cost of administration of the workhouse infirmary, where no zymotic diseases were taken. The cost per bed in Newcastle (£411) also compared favourably with that of larger hospitals—e.g., in Liverpool £415 and in Edinburgh £559 per bed. Considerable argument also arose concerning the large numbers of the staff for the number of patients in hospital, which at that moment happened to be abnormally small. But the difficulties and the cost of administration of an infectious diseases hospital where several different diseases are treated is always a stumbling-block to those who have had no practical experience of fever hospitals. In the result the estimates were reduced by £4000 and this very probably largely in view of the immediate outlook in the main industry of the Tyne and in response to the appeal of Sir W. H. Stephenson that spending committees should bear this rather depressing outlook in mind and so arrange their expenditure that the rate should not exceed that of last year —viz., 4*s.* 11*d.* in the £. The decision of the council will no doubt be somewhat disappointing to the members of the sanitary committee and their able and energetic officer of health, Dr. Henry E. Armstrong, for it is universally admitted that Newcastle is in the proud position of being at least among the foremost sanitary administrations of the country; but, at the same time, they have the satisfaction of knowing that the thanks of the whole community are due to them for their wisdom and foresight in matters of preventive medicine, as well as the further satisfaction of knowing that theirs is not the only committee whose expenses have had to be curtailed in view of the present state of affairs.

April 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Royal Infirmary: Post-graduate Classes.

DURING the last two years carefully arranged post-graduate courses have been conducted at the Glasgow Royal Infirmary and have attracted practitioners not only from the city and neighbourhood of Glasgow but also from considerable distances. This year arrangements have been made for two separate courses: the first, mostly devoted to special subjects, will begin on Friday, May 1st, and will continue during the month; the second will commence at the beginning of September, the syllabus of which has still to be arranged. The following subjects will be included in the first course: Clinical medicine, by Dr. G. S. Middleton and Dr. W. K. Hunter; Clinical Surgery, by Mr. Henry Rutherfurd and Mr. A. N. McGregor; Surgical Diseases of the Urinary Organs, by Mr. David Newman; Clinical Examination of the Urine, by Dr. John Henderson; Gynæcology, by Dr. G. B. Marshall; Diseases of the Ear, by Dr. J. K. Love; Diseases of the Eye, by Mr. John Rowan; Diseases of the Skin, by Dr. A. Morton; Diseases of the Throat and Nose, by Dr. R. Fullerton; Gynæcology, by Dr. W. D. Macfarlane; Operative Surgery, by Mr. P. Paterson; and Bacteriology, by Mr. David McCrorie. Details of the course have appeared in the advertising columns of THE LANCET, and a syllabus may be had by applying to the superintendent of the infirmary, who will be pleased to supply any further information. As many of the classes are limited to a fixed number of members, practitioners desirous of joining any of the classes are recommended to apply for enrolment as early as possible.

Aberdeen Parish Council and Medical Appointments.

At the last monthly meeting of the Aberdeen parish council held on April 14th it was agreed to raise the resident medical officer's salary from £80 to £90. A motion that vaccination defaulters should not be prosecuted was defeated by a large majority. In connexion with the appointments of the district medical officers, who have hitherto held office *ad vitam aut culpam*, a motion was brought forward—

> That at the ordinary meeting on April 14th the parish council proceed to consider, and if thought fit to alter or vary, the appointment of all or any of the district medical officers.

It was also moved that, with the view of establishing a rotation, the senior medical officer should be now asked to retire and this ultimately became the finding of the meeting. The senior medical officer will now be asked to resign in accordance with the decision of the council. Dr. Clark, with a view to qualifying for the position, then intimated his resignation as a member of the parish council.

The Health Report for Keith.

Dr. R. S. Turner, medical officer of health of Keith, has just issued his report to the town council for the year 1907. Reference is made to the defective water-supply and the insanitary condition of many of the ash-pits and disused drains. Nothing has been done during the year to prevent the pollution of the Isla by trade effluents and the sewage purification scheme seems to be at a standstill. The death-rate has been 20·4, as compared with 19·4 for 1906, the increase having been chiefly in persons over 60 years of age.

The Public Health of Peterhead: Annual Reports.

In the course of his report to the Local Government Board the medical officer states that the birth-rate and death-rate are respectively 34·6 per 1000 and 19·5 per 1000 of the population. The mortality of children under one year is slightly increased for this year, the rate being 152·8 per 1000 births, in comparison with 149·8 per 1000 births for last year. On the periods 1–5 years, 5–15 years, and 15–25 years there is also a slight increase, as also in the mature and post-mature periods, on the preceding year. There have also been a good many deaths from zymotic causes, but the mortality from tuberculous disease is considerably less. Dr. Norman Davidson refers to the scarcity of houses for the working classes and regards the situation as one demanding serious attention. Certain parts of the town are seriously congested and overcrowded both as to the poorer class of house and better-class workmen's houses. For some time past the local authorities have recognised the need for improvement and have so far got a report from the burgh surveyor and town clerk regarding the advisability of erecting workmen's houses under the Housing of the Working Classes Act, 1890. In the sanitary inspector's report the facts regarding the new water-supply are noted. Great care is being taken to trace all springs to their sources and to exclude all doubtful water. Although filtration was not anticipated to be necessary, since the epidemic of enteric fever the question has been under consideration. New water mains are being largely substituted for the old and inadequate mains.

out the necessary works required of them." Of the 94 local authorities within the district, 80 urban and ten rural districts have works in operation, leaving two urban and one rural district with no scheme, and one urban district with a scheme under consideration. The enormous amount of consideration required before these schemes are allowed to escape from review is something to marvel at. The two rivers have on their banks 393 manufacturers, of whom 298 have efficient works, while 83 are in the unsatisfactory position of having works which are not efficient. 14 only let their effluent go without treatment, and there seem to be 26 works where, unless they have been closed, the effluent goes into the sewers. Our old opprobrium, the Gore Brook, receives, and well deserves, special mention, for "there is still the foul state of the Gore Brook to be remedied," but Sir John Hibbert knows that Gorton is to be amalgamated with Manchester and trusts "that this long-standing nuisance will at last be remedied." Though many think that more might have been done to make our streams a delight to the eye instead of a trial to the nose, it would not be fair not to give the testimony of the chief inspector that "the improvement of the rivers is evidenced by the appearance of the river bed, by the continued and increasing use of river water by the manufacturers, and particularly by the reduction in the number of complaints." Unfortunately it is not often that the eye can penetrate to the river bottom. The services of Sir John Hibbert, his kindness and urbanity, were warmly acknowledged. Mr. D. B. Hewitt of Davenham was elected to the chairmanship, and as he is a retired member of our profession he will understand the difficulties and also the possibilities of river purification.

"Potted Lobster."

A Southport firm was prosecuted the other week at Blackpool and fined £3 and costs for selling potted lobster "not of the nature and substance demanded by the purchaser." This stuff was said to have contained only 25 per cent. of pure lobster, while there were 50 per cent. of foreign fish. Colouring matter and a preservative were said also to have been introduced. A member of the firm denied the statement of the analyst that it contained bread but said that it did contain ground rice. He stated that formerly the label described this compound as a mixture, but when it was explained to him that he was the only one in the trade who did so he stopped it, "though he had no intention to defraud." However, he said that he had made provision in the future to fully explain on the label that the contents of the pot were lobster, choice fish, and other things.

April 21st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Lord Mayor of Liverpool and the University of Edinburgh.

AMONGST the recipients of the degree of Doctor of Laws at the spring graduation ceremony which took place at the University of Edinburgh on April 10th was Dr. Richard Caton (Lord Mayor of Liverpool). Sir Ludovic Grant, in presenting Dr. Caton, said that he possessed a triple qualification for the honorary degree of LL.D.—his services to medical science and medical education, his archæological achievements, his public activity and civic prestige. Dr. Caton was an alumnus of the University of Edinburgh. He was one of the band of labourers whose strenuous exertions were instrumental in calling into existence the University of Liverpool and he himself discharged the duties of professor of physiology for many years with conspicuous success.

The Dutton Memorial.

The fund being collected as a memorial to the late Dr. J. Everett Dutton, who died two years ago when on an expedition for the Liverpool School of Tropical Medicine, is now approaching completion. The object of the promoters of the memorial is to secure the means of endowing an additional chair in the Liverpool School of Tropical Medicine, to be called the "Dutton" chair. More than two-thirds of the required amount have been already promised, the activity of Sir Rubert Boyce, the indefatigable professor of pathology at the University, being largely responsible for this happy result. Dr. Dutton well deserves a permanent memorial at the University of Liverpool. He gave his life in the service of science and humanity and his achievements will ever remain one of the traditions of the Liverpool School of Tropical Medicine. The memorial to him will take the form of additional facilities for carrying on effectively the study of tropical diseases.

Closing of the Park Hill Civic Hospital.

The chairman of the hospitals committee (Mr. John Utting) at the recent meeting of the city council made the announcement that the Park Hill hospital for infectious diseases had been closed. The hospital contained 350 beds and they were all now out of commission. The committee, however, desired to keep a certain number of the beds in a state of constant preparedness. For that purpose it was retaining six officers in the hospital. They would have certain duties to discharge whilst the hospital was empty and they would be ready to take in any number of cases up to 40 should any sudden emergency arise. It was proposed to give the gentleman who had been the visiting physician a retaining fee, so that they might have his services when required. At present there were, fortunately, no small-pox cases in Liverpool, and the small-pox hospital was just now being used as a convalescent institution. As long as that continued they need not call upon the Park Hill hospital again. Mr. Utting regarded the new arrangement as a very valuable insurance against any misfortune which might befall the health of the city.

April 21st.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The College of Medicine.

THE University Easter term begins on Friday, April 24th. The registration of students at the College of Medicine commences on the 22nd and the books remain open until Saturday, April 25th. The first lectures of the summer session will be given on Monday, the 27th. In former years the summer session began on May 1st but in view of the alteration of the dates of the examinations it has been found necessary to antedate the commencement of the summer session. On the suggestion of Professor G. R. Murray a short course of post-graduate lectures, especially intended for medical practitioners, was given last summer on The Principles of Bacteriology and Immunity, with special reference to their application in the ordinary routine of medical practice. The number of practitioners who attended was so encouraging that a similar course will be given during the coming summer on Tuesday afternoons at 4 P.M., when it if hoped that the attendance will again be such as to warrant the authorities in making this a regular course of instruction.

Anthrax in Newcastle.

Some meat recently sent to the Newcastle market for sale as food—"subject to inspection"—was found on examination to be infected with anthrax. Inquiry at the farm whence the meat had been sent showed that there was a serious outbreak of anthrax among the beasts and other animals kept there. Several beasts, some pigs, and a pony were all found to be suffering from anthrax and some of them subsequently died from the disease. In this particular instance, happily, no further cases, either in man or animals, have been traced to the outbreak. In similar circumstances some few months ago three cases of anthrax in man were directly traced to an infected animal which had died suddenly. Two butchers who dressed the carcass contracted the disease, one of whom died, and a woman who bought some of the meat also suffered but recovered. During the first three months of this year ten cases of anthrax in bovine animals were notified in the county of Northumberland, and a study of the incidence of the disease points to "cake," which is largely used as a foodstuff, as the cause of the disease. After each case is notified the farm is visited by the chief veterinary inspector for the county and the burial of the carcass is carried out according to the instructions contained in the order of the Board of Agriculture under his immediate supervision. The efficiency with which the work is done is proved by the fact that it is very rarely indeed that a second case of the disease occurs on the same farm. In favour also of the view that the disease is imported is the fact that the cases are distributed all over lectures which were delivered in connexion with the exhibition, and which is to be carried out by Messrs. Maunsel and Co., 96, Middle Abbey-street, Dublin. The collection is to appear in three volumes. Of these, the first volume has been promised to be "ready early in April" and contains a preface by Her Excellency the Countess of Aberdeen, an account of the opening ceremony of the exhibition, and the following lectures: What the Public Can Do in the Fight against Tuberculosis, by Professor Osler; Tuberculosis in Ireland, by Sir Robert Matheson; On the Bearing of Tuberculosis on the Conditions of Ireland, by Mr. R. F. Tobin, F.R.C.S. Irel.; Why Tuberculosis is so Common in Ireland, by Sir John W. Byers; Some Aspects of the Tuberculosis Problem, by Dr. Lawson; on the Economic Aspects of Tuberculosis, by Professor J. A. Lindsay; and a catalogue of the above exhibition. The second volume of the series will deal with the sanatorium and dispensary treatment of the disease, &c.; while the third will be made to include a number of miscellaneous lectures bearing on the subject, inclusive of one dealing with Tuberculosis in the Lower Animals. The publication of the series should have a most beneficial effect in educating the public in their necessary duties in the campaign against tuberculosis.

A Memorial to the late Dr. Conolly Norman.

A meeting was held recently in the Royal College of Physicians of Ireland to consider the question of erecting a suitable memorial to the memory of the late Dr. Conolly Norman. The President of the College presided. Also present were Sir Henry R. Swanzy, President of the Royal College of Surgeons in Ireland; Dr. J. Little, Sir Francis R. Cruise, Sir Thornley Stoker, Dr. J. Magee Finny, Dr. W. R. Dawson, Dr. P. W. Maxwell, Dr. J. O'Conor Donelan, Dr. A. W. W. Baker, Dr. E. L. Fleury, Mr. H. M. Cullinan, Rev. M. Taylor, Mr. J. R. O'Connell, LL.D., and Dr. Carroll. Dr. Little and Sir Francis Cruise expressed sympathy with the object of the meeting. Sir Henry Swanzy paid tribute to the memory of the late Dr. Conolly Norman. After some discussion an executive committee was appointed. Dr. Dawson and Mr. O'Connell were appointed treasurers, and Dr. Donelan and Dr. Fleury secretaries.

The University Question: the Belfast View.

Mr. Birrell's Bill being now printed is undergoing very critical discussion in Ireland, and while there are the most marked divergencies of opinion on many of the details as to the two universities, and still more as to the line of settlement adopted by the Chief Secretary, all are agreed that the finances are not at all sufficient. Naturally, the President, professors, and lecturers at Queen's College, Belfast, are well satisfied, as is shown by the following motions adopted on April 7th:—

> 1. That we desire to express our extreme gratification that an earnest attempt is being made to settle the Irish University question on a permanent basis. 2. That we rejoice that the provisions of the Bill insure that the proposed new University in Belfast shall stand upon the same broad, non-sectarian, and purely academic basis on which Queen's College, Belfast, has worked since its establishment; that the University shall be free from religious tests and from all ecclesiastical control; that it is to be a free and completely self-governing university; and that public bodies, benefactors, professors, graduates, secondary teachers, women, and students will be represented on its governing body. 3. That, in our opinion, the elevation of this college to university rank will not only add much to the dignity of Belfast, making it a university city, but will give a great impetus to higher education here and throughout Ulster; that it will stimulate both teachers and students to show themselves worthy of the higher status now proposed to be granted by the Legislature; that it will excite much greater public interest in the college and attract an increasing amount of public support from local benefactors, and that it will largely stimulate literary and scientific research and promote the diffusion of knowledge and culture throughout the north of Ireland. 4. That a copy of these resolutions be forwarded to the Chief Secretary and to the press.

On the other hand, the friends of Magee College (which is the only constituent college of the Royal University not recognised by the new Bill) are up in arms, and at the closing meeting of the session on April 8th the President protested very strongly against Mr. Birrell's treatment of that institution. Then one of the visitors of Queen's College, the Right Hon. Thos. Sinclair, D.L., D.Lit., the leading layman of the Presbyterian Church, has written a letter to the papers denouncing the Chief Secretary's Bill and stating that he does not think "a more retrograde and mischievous proposal has yet been made"; and at a meeting of the executive committee of the Royal University Graduates Association held on April 9th it was unanimously decided to oppose Mr. Birrell's University Bill and a subcommittee was appointed to draft a statement and to consider further action.

The corporation of Cork has passed a resolution expressing its opinion that no settlement of the question can be considered final or satisfactory which does not provide Cork with independent university powers.

Belfast Ophthalmic Institution.

At the annual meeting of the friends of this hospital, held on April 13th, it was reported that during the past year there were in the extern department 1372 new eye patients and 703 suffering from affections of the nose, ear, and throat, while in the wards 173 patients were treated. There is a balance against the hospital of £150, and the total subscriptions received were £93. The medical staff is anxious for internal alterations and improvements in the hospital, which will cost about £500. It is hoped that an effort will be made to carry out these very necessary improvements and to free the institution from debt.

Benn Ulster Eye, Ear, and Throat Hospital.

At the annual meeting of the supporters of this hospital held on April 10th, it was reported that 354 patients had been treated in the wards during the past year and 2797 in the extern department. Financially, the debt on the hospital has been reduced to £194. 170 operations were performed under general anæsthesia, the latter including 54 operations for cataract.

The Proposed Dispensary for Consumption in Belfast.

A communication was read at the weekly meeting of the Belfast public health committee on April 9th from the Local Government Board, pointing out that it could not approve of the proposed arrangement with the Forster Green Hospital for the establishment of a dispensary for the treatment of consumption, as it had been advised that it could not legally do so. The Board suggested to the committee that it should if possible arrange with the committee of management of the hospital to place ten additional beds at its disposal, and it was resolved that the chairman should be authorised to negotiate with the hospital authorities with the view of acting on the advice of the Local Government Board.

The University Bill.

At a large meeting of the Belfast National Teachers' Association held on April 11th a motion was unanimously carried "emphatically protesting against the proposals in the Chief Secretary's Irish University Bill which exclude extern students from University examinations and which prohibit them from obtaining University degrees, as has been the custom for upwards of a quarter of a century." At a meeting of the higher education committee of the Presbyterian Church in Ireland held on April 15th it was agreed to request the Moderator to call a special meeting of the members to consider the proposed legislation of the Government with regard to University education in Ireland. The importance of this meeting lies in the fact that in Queen's College, Belfast, as is shown by the following figures for 1906–07 (the last available statistics), the Presbyterian students were actually 239 out of a total of 390, and consequently the Presbyterian Church is deeply interested in the proposed scheme.

Down District Asylum.

Mr. Michael J. Nolan, medical superintendent of the Down District Asylum at Downpatrick, has had his salary increased by the committee of management from £700 to £900 per annum.

Waste-paper Nuisance in Belfast.

The public health committee of Belfast, with a view to improve the appearance of the city, by preventing the scattering of waste-paper over the thoroughfares, has decided to adopt the plan used in Glasgow—that is, to supply canvas bags, in which the employees of shops are requested to place papers to be called for by the health authorities, instead of, as now, the papers being placed in a box or basket on the footpath along with the ashes. Householders are also requested to ask their servants when sweeping from the house door to the footway and on to the street to pick up pieces of paper and to burn them in the kitchen range instead of sweeping them on to the street.

Death of Mr. William Aickin, M.D. R.U.I.

A member of the medical profession, well-known for many years in Belfast, died at the age of 74 years, at his residence, Sandown Park, Knock, co. Down, on April 16th. He had been in practice in Belfast up to four years ago, when he retired owing to failing health. Dr. Aickin, who was the out the necessary works required of them." Of the 94 local authorities within the district, 80 urban and ten rural districts have works in operation, leaving two urban and one rural district with no scheme, and one urban district with a scheme under consideration. The enormous amount of consideration required before these schemes are allowed to escape from review is something to marvel at. The two rivers have on their banks 393 manufacturers, of whom 296 have efficient works, while 83 are in the unsatisfactory position of having works which are not efficient. 14 only let their effluent go without treatment, and there seem to be 25 works where, unless they have been closed, the effluent goes into the sewers. Our old opprobrium, the Gore Brook, receives, and well deserves, special mention, for "there is still the foul state of the Gore Brook to be remedied," but Sir John Hibbert knows that Gorton is to be amalgamated with Manchester and trusts "that this long-standing nuisance will at last be remedied." Though many think that more might have been done to make our streams a delight to the eye instead of a trial to the nose, it would not be fair not to give the testimony of the chief inspector that "the improvement of the rivers is evidenced by the appearance of the river bed, by the continued and increasing use of river water by the manufacturers, and particularly by the reduction in the number of complaints." Unfortunately it is not often that the eye can penetrate to the river bottom. The services of Sir John Hibbert, his kindness and urbanity, were warmly acknowledged. Mr. D. B. Hewitt of Davenham was elected to the chairmanship, and as he is a retired member of our profession he will understand the difficulties and also the possibilities of river purification.

"Potted Lobster."

A Southport firm was prosecuted the other week at Blackpool and fined £3 and costs for selling potted lobster "not of the nature and substance demanded by the purchaser." This stuff was said to have contained only 25 per cent. of pure lobster, while there were 50 per cent. of foreign fish. Colouring matter and a preservative were said also to have been introduced. A member of the firm denied the statement of the analyst that it contained bread but said that it did contain ground rice. He stated that formerly the label described this compound as a mixture, but when it was explained to him that he was the only one in the trade who did so he stopped it, "though he had no intention to defraud." However, he said that he had made provision in the future to fully explain on the label that the contents of the pot were lobster, choice fish, and other things.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Lord Mayor of Liverpool and the University of Edinburgh.

AMONGST the recipients of the degree of Doctor of Laws at the spring graduation ceremony which took place at the University of Edinburgh on April 10th was Dr. Richard Caton (Lord Mayor of Liverpool). Sir Ludovic Grant, in presenting Dr. Caton, said that he possessed a triple qualification for the honorary degree of LL.D.—his services to medical science and medical education, his archæological achievements, his public activity and civic prestige. Dr. Caton was an alumnus of the University of Edinburgh. He was one of the band of labourers whose strenuous exertions were instrumental in calling into existence the University of Liverpool and he himself discharged the duties of professor of physiology for many years with conspicuous success.

The Dutton Memorial.

The fund being collected as a memorial to the late Dr. J. Everett Dutton, who died two years ago when on an expedition for the Liverpool School of Tropical Medicine, is now approaching completion. The object of the promoters of the memorial is to secure the means of endowing an additional chair in the Liverpool School of Tropical Medicine, to be called the "Dutton" chair. More than two-thirds of the required amount have been already promised, the activity of Sir Robert Boyce, the indefatigable professor of pathology at the University, being largely responsible for this happy result. Dr. Dutton well deserves a permanent memorial at the University of Liverpool. He gave his life in the service of science and humanity and his achievements will ever remain one of the traditions of the Liverpool School of Tropical Medicine. The memorial to him will take the form of additional facilities for carrying on effectively the study of tropical diseases.

Closing of the Park Hill Civic Hospital.

The chairman of the hospitals committee (Mr. John Utting) at the recent meeting of the city council made the announcement that the Park Hill hospital for infectious diseases had been closed. The hospital contained 350 beds and they were all now out of commission. The committee, however, desired to keep a certain number of the beds in a state of constant preparedness. For that purpose it was retaining six officers in the hospital. They would have certain duties to discharge whilst the hospital was empty and they would be ready to take in any number of cases up to 40 should any sudden emergency arise. It was proposed to give the gentleman who had been the visiting physician a retaining fee, so that they might have his services when required. At present there were, fortunately, no small-pox cases in Liverpool, and the small-pox hospital was just now being used as a convalescent institution. As long as that continued they need not call upon the Park Hill hospital again. Mr. Utting regarded the new arrangement as a very valuable insurance against any misfortune which might befall the health of the city.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The College of Medicine.

THE University Easter term begins on Friday, April 24th. The registration of students at the College of Medicine commences on the 22nd and the books remain open until Saturday, April 25th. The first lectures of the summer session will be given on Monday, the 27th. In former years the summer session began on May 1st but in view of the alteration of the dates of the examinations it has been found necessary to antedate the commencement of the summer session. On the suggestion of Professor G. R. Murray a short course of post-graduate lectures, especially intended for medical practitioners, was given last summer on The Principles of Bacteriology and Immunity, with special reference to their application in the ordinary routine of medical practice. The number of practitioners who attended was so encouraging that a similar course will be given during the coming summer on Tuesday afternoons at 4 P.M., when it if hoped that the attendance will again be such as to warrant the authorities in making this a regular course of instruction.

Anthrax in Newcastle.

Some meat recently sent to the Newcastle market for sale as food—"subject to inspection"—was found on examination to be infected with anthrax. Inquiry at the farm whence the meat had been sent showed that there was a serious outbreak of anthrax among the beasts and other animals kept there. Several beasts, some pigs, and a pony were all found to be suffering from anthrax and some of them subsequently died from the disease. In this particular instance, happily, no further cases, either in man or animals, have been traced to the outbreak. In similar circumstances some few months ago three cases of anthrax in man were directly traced to an infected animal which had died suddenly. Two butchers who dressed the carcass contracted the disease, one of whom died, and a woman who bought some of the meat also suffered but recovered. During the first three months of this year ten cases of anthrax in bovine animals were notified in the county of Northumberland, and a study of the incidence of the disease points to "cake," which is largely used as a foodstuff, as the cause of the disease. After each case is notified the farm is visited by the chief veterinary inspector for the county and the burial of the carcass is carried out according to the instructions contained in the order of the Board of Agriculture under his immediate supervision. The efficiency with which the work is done is proved by the fact that it is very rarely indeed that a second case of the disease occurs on the same farm. In favour also of the view that the disease is imported is the fact that the cases are distributed all over patients were allowed to walk about at their own discretion. Dr. Determann (Freiburg) spoke on the subject of the Viscosity of the Blood at High Altitudes. He has been able to examine patients in Freiburg, which is situated at an altitude of 280 metres above the sea, and in St. Moritz (1840 metres above the sea). In those places he found the viscosity to increase in some persons at once and in others after several days. The maximum was reached and remained constant after ten days. The natives of St. Moritz showed the same phenomenon, which was, in Dr. Determann's opinion, caused by the diminution of oxygen inhaled at those altitudes causing an acceleration of the circulation in the lungs, so that the hæmatogenic organ must develop increased activity. The viscosity was very important for the circulation, which depended on the force of the heart and of the vessels as well as on the quality of the blood. Dr. Selig (Franzensbad) read a paper on the Influence of Athletic Sports on the Heart. A rational indulgence in such sports was recommendable from a medical point of view. Experiments showed that both the blood pressure and the pulse-rate increased after moderate exercises. Even patients suffering from valvular diseases of the heart were able to do the test work and only in myocarditis symptoms of insufficiency appeared. After over-exertion, however, severe symptoms might appear; the pulse-rate might attain a frequency of 187 and a decrease of 40 millimetres of mercury in the blood pressure has been observed. Neurosis of the heart often developed in athletes and the history of patients suffering from heart diseases showed over-exertion more frequently than was generally supposed. Over-exertion in cycling was especially prejudicial to the heart, while tennis was less injurious because it required less exertion, but even tennis was dangerous for chlorotic girls if played for too long a time. The old German gymnastics by which the whole body was exercised generally were preferable to the modern forms of athletics. The treatment of anæmia was discussed by Dr. Ziegler (Breslau). With regard to internal treatment he said that certain medicines were undoubtedly able to improve the composition of the blood. Iron, for instance, had a stimulating action on the cells and on the secretion of internal glands. Arsenic acted by destroying certain cells and by a consequent over-production of new cells. Thus its action was very like that of venesection and of transfusion. The increase of the red corpuscles in high altitudes was only an apparent one and was caused by loss of water and by a quicker development of the corpuscles perhaps under the influence of the sun. Frequent examination of the blood was essential for ascertaining the efficacy of treatment in anæmia; the presence of normoblasts and of polychromatophilic erythrocytes gave a good prognosis. Dr. Kisch (Marienbad) read a paper on Spastic Constipation, of which the symptoms were painful defæcation, a feeling as if fæces were still left in the rectum after defæcation, hypersensibility of the abdominal walls, and spasm of the sphincter. For treatment he recommended rest and a strengthening diet, with exclusion of food which tended to cause flatulence. The administration of belladonna and of atropine was to be recommended, and good results were obtained by mud baths, whilst massage and electricity were contra-indicated. Dr. Riedel (Berlin) presented a report of his researches concerning the internal administration of radium in the form of radiogen. Radiogen was produced by pressing water through a filter containing radium. Radiogen was given for a long time without producing any obvious effect and in the urine even after the administration of 100,000 units no emanation of radium was present. Dr. Riedel has treated nearly 100 patients by radiogen, the result being that some of them were benefited whilst others were not influenced at all. Other papers read before the congress dealt with Neurosis of the Heart, by Dr. Jacob of Kudowa; the Diagnosis of Pulmonary Diseases by Radiography, by Dr. Kraft of Goerbersdorf; and the Treatment of Tuberculosis of the Joints, by Dr. Tietze of Breslau.

The Management of Labour.

According to a paper by Professor Martin in the *Monatsschrift für Geburtshülfe und Gynäkologie* and quoted in the *Berliner Klinische Wochenschrift* he allowed 100 women in whom delivery had been normal and whose internal organs were healthy to leave their beds the day after delivery. Care was taken that they sat in comfortable chairs, the abdomen being compressed by a firm bandage, and they were not permitted either to walk about or to do any kind of The results were very satisfactory, the bowels and urine no trouble, and the involution of the uterus proceeded in normal way. Professor Martin recommended this method in all normal confinements in cases where an infection is unlikely to occur.

Infection by Gonococci through the Skin.

At a recent meeting of the Berlin Ophthalmological Society Dr. Schoelor reported the case of a nurse who in nursing a child suffering from gonorrhœal conjunctivitis received a slight injury on the right forefinger. Necrosis of the epidermis and an ulcer developed, and on microscopical examination diplococci with a negative Gram-reaction were found. An abscess on the femur ensued and the patient died from septicæmia. This was the first case where a general septicæmia was caused by the entrance of gonococci through the skin.

April 20th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Finsen Medical Light Institute.

ON April 14th the King and the Royal Family honoured the memory of Niels R. Finsen in being present at the inauguration of the clinic for internal diseases in connexion with the Finsen Medical Light Institute. Ever since Professor Finsen began to study the action of actinic rays he regarded the universal effect of the rays on the organism as being of the highest interest and importance. In his last address to the board of directors of the Light Institute he expressed his belief that the light rays as a therapeutic means would be particularly valuable in the form of light baths in chronic diseases, such as diseases of the blood, of metabolism, or of the circulatory system. But Finsen did not live to see his ideas on this point carried out. After his death certain investigations on the universal action of light rays, made by Dr. K. A. Hasselbalch, now director of the Finsen Institute Laboratory, are claimed to support Finsen's ideas, particularly as regards certain diseases of the heart, and in consequence the new clinic has been erected. It accommodates 32 in-patients and has, moreover, a large out-patient department. Of course, the chief work of the clinic will be the study of the general action of the light rays on the diseased organism, but its magnificent equipment enables it to apply all modern methods of physical and dietetic treatment. To the best knowledge of your correspondent Denmark is so far the only country in which the medical profession has had any opportunity of testing the value of the new light bath treatment for diseases of the circulatory system as carried out in the Finsen Medical Light Institute. A report on the discussions on this topic in the medical societies of Copenhagen might therefore perhaps interest the readers of THE LANCET. When the director of the laboratory of the Copenhagen Institute, Dr. Hasselbalch, made his first communication on the subject he claimed that the treatment brought about a lasting dilatation of the vessels of the skin and simultaneously a decrease of the blood pressure lasting for more than a month after the light bath. He proposed, therefore, to apply the bath to diseased conditions in which a decrease of the arterial pressure was desired. At a meeting of the Medical Society of Copenhagen Dr. H. Jacobæus of the Finsen Institute reported on a series of 15 cases of angina pectoris treated in the way above mentioned. In a man aged 67 years the very grave and painful attacks ceased under the bath treatment, while another patient who for several years had suffered from anginous symptoms was completely relieved after a very short treatment; some months afterwards the attacks recurred but disappeared again after a second treatment. In 12 other cases greater or less improvement occurred and only in one case did the light bath treatment fail to influence the condition. Also other forms of heart disease seemed to benefit from the treatment. In the ensuing discussion Professor Chr. Gram said that the material was too small and the time of observation too short to allow of forming any opinion as to the curative effect of the light baths. Improvement in cases of angina pectoris was often observed either spontaneously even for somewhat long periods of time or as a result of the usual medical treatment. It was orehill reservoir is being enlarged in capacity from ,000,000 gallons to 6,000,000 gallons. Grange reservoir will remain untouched and will probably not be used for the burgh supply, as it is intended to provide a balancing clean water tank to hold 300,000 gallons. The tank will be covered to prevent contamination of the filtered water. The estimated cost of the whole works is £35,900. It is also proposed to expend a large sum of money on the main drainage of the town. A number of the sewers are built of stone and are in a most unsatisfactory condition. For these it is proposed to substitute fireclay sewers, and while much of the drainage of private property has been overhauled during the year there is still much to be done in this respect. The sanitary inspector also declares that, in spite of adverse circumstances, the town has enjoyed a hitherto unprecedented prosperity.

Death of Dr. John Reid.

On April 14th the death occurred at Clifton House, Dinnet, of Dr. John Reid, a man who was held in high esteem in the district. Dr. Reid, who was a graduate of the University of Aberdeen, was born at Logie Coldstone in 1836. At the age of 30 he was appointed medical officer to the Assam Tea Planting Company. He held this appointment for nine years and then took over the Deesang Tea Planting Company which he carried on for a number of years with marked success. Returning to this country he resolved to spend the declining years of his life near the spot where he was born and brought up, and there also he died. Dr. Reid was twice married and is survived by his widow but has left no family. The funeral took place in Coldstone churchyard in the presence of a large and representative gathering.

April 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Meath Hospital and County of Dublin Infirmary.

THE annual meeting of the supporters of the Meath Hospital and County of Dublin Infirmary was held on April 13th in the board room of the hospital. The financial report showed a balance against the hospital at the close of the year of £6610. The hospital has special claims on public support, for it is actually the first institution in which modern clinical teaching was initiated, its pioneers being Dr. Robert Graves and Dr. William Stokes. The cosmopolitan reputations of those pioneers has been "modernised" in the present generation by those of the present senior surgeon and senior physician of the institution—Sir Lambert Hepenstal Ormsby and Sir John William Moore—who have respectively contributed volumes of corresponding originality of scientific attainment and of mastery of scholarly exposition to the libraries of their own specialties. And as the former of these gentlemen forcibly put it in moving the adoption of the report, the institution has for 154 years been giving help to the suffering poor without distinction of class or creed, while the result of modern advances in surgery by accelerating cure enabled it to benefit a much larger number. In the somewhat stormy period of the introduction of antisepsis Sir Lambert Ormsby was, as is well remembered, one of the most earnest and intelligible of the speakers at the reiterated discussions. So that in many departments the Meath Hospital occupies a position which is unique among Dublin institutions.

Lady Governor of Richmond Asylum.

Mrs. MacDowell Cosgrave, the wife of a leading physician of Dublin and member of the professorial staff of the school of surgery of the Royal College of Surgeons, has been elected to the board of governors of the Richmond Lunatic Asylum. This is the first instance of the admission of a lady to the membership of that body or, I believe, to that of any corresponding body in Ireland. The election is an extremely popular one; the choice has been made by the municipal corporation, to which the energy and judgment of Mrs. MacDowell Cosgrave had become thoroughly familiar during a series of years as guardian of the North Dublin Union. The excellent quality of her aims and results during a prolonged period of Poor-law guardianship is well proved by the fact that these have won the confidence of a body of the members of which the great majority have been opposed to her both in creed and in politics. So that while the new lady governor is to be congratulated on her election our municipal corporation is to be congratulated on a display of liberality.

Women's National Health Association of Ireland: Its Inaugural Meeting.

On April 14th the first annual meeting of the Women's National Health Association of Ireland was held under the presidency of Her Excellency the Countess of Aberdeen. There were gathered together the representatives of all the important centres of Ireland, a truce being declared between opposing classes and creeds for the general betterment of the victims of disease and poverty. The association met in Leinster House, Kildare-street. Her Excellency took the opportunity of announcing the tangible results which had already been attained by the efforts made in connexion with the Tuberculosis Exhibition, laying stress upon the following points: 1. Everywhere the increase of open windows is remarkable and that, too, in the poorest parts of the towns visited. 2. Applications from tenants for alterations, so that windows and skylights may open without letting in the rain, are becoming common. 3. A great decrease in the habit of spitting is noticeable. 4. In some places various steps are being taken to secure a purer milk-supply. To mention one place in particular—Armagh—those supplying milk there have agreed to have all their herds submitted to the tuberculin test; and at the large lunatic asylum there a resolution has been passed to the effect that no milk will be accepted there unless it comes from herds so tested. 5. In several places the Poor-law guardians are considering the addition of inexpensive annexes or the setting apart of special wards for advanced consumptive cases. 6. In some places there is a movement for erecting inexpensive cottage sanatoriums. 7. Nurse visitors for cases of consumption have been established in three places and are being considered in others. These evidences and the eagerness of the people to learn more, to come to further lectures, and to talk over health matters, show how ready the soil is for further seed-sowing. It would appear that few crusades against disease have had so promising a first year's record, and there is every prospect that the enthusiasm and persevering energy of Her Excellency will secure a continuance of corresponding success while she retains the leadership. As regards the question of infant mortality Lady Aberdeen said: "We are only beginning our work in connexion with infant mortality, but several of the branches intend taking it in hand this summer and we would specially draw our members' attention to the success which has attended the experiment made in Belfast in one district by the establishment of a system for visiting newly made mothers or babies' clubs, on the line of the School for Mothers at St. Pancras, where young mothers are invited to come and to bring their babies for advice as to their management, where the children can be weighed, and where great good can be done in preventing wrong feeding and in preaching the pre-eminent value of breast-feeding. Irish mothers, happily, adhere to this practice more than most modern mothers, and it must be our aim not only to confirm them in this, but to see to it that the mothers themselves are properly nourished both before and after the birth of their children. You will notice that ere long we hope to have a Pasteurised milk laboratory here in Dublin, through the kindness of Mr. Nathan Strauss, and we shall hope to report satisfactorily regarding this later on. Please make people understand that we, as an association, hold that the only ideal milk is that which comes undiluted, uncontaminated, from a perfectly healthy cow, housed in a well-ventilated cowshed, and milked by clean hands. But we equally believe that such a supply of milk is practically an impossibility in our large towns at the present time. And so we advocate a careful system of Pasteurised milk as a makeshift to save our children from tuberculosis, summer diseases, and many other troubles. Meanwhile, let all our branches study the new Dairy and Cowshed Order issued by the Local Government Board, which comes into force on May 1st and which should do much to secure a purer milk-supply if properly enforced."

Literature of the Campaign against Tuberculosis in Ireland.

The issue[1] of Professor W. Osler's opening lecture at the Tuberculosis Exhibition held in Dublin, October, 1907, is but the preliminary step towards publication of the series of for the protection of poor helpless children from some of the dangers to which they are exposed. A league was formed one and a half years ago for carrying out these objects and during the whole of this time it has worked with unflagging energy. The league owns a large building in Budapest where destitute children are provided for, those who are ill being accommodated in the hospital section where medical attendance is gratuitous. Delicate children are sent to the seaside during the summer months. A large sanatorium is to be erected next year in the vicinity of Fiume on the Adriatic for the reception of scrofulous children. Contributions to the fund of the league are solicited on a very clever system. Once or twice in a year a day is appointed when merchants and manufacturers pay to the league a certain proportion (about 1 per cent.) of their takings for that day. They do this willingly, because what they lose by allowing 1 per cent. for the charity they regain from the profits on increased sales, because the benevolent portion of the public buys largely on this day when they know that a share of their money goes to serve a charitable purpose. This year the so-called "Children's Day" was kept on April 2nd. On this day the elementary schools are closed and in the streets ladies and girls are in charge of collecting boxes into which they invite the passers-by to drop contributions. Bands of music play in the streets and crowds of children assemble to listen to them; the theatres also hold children's matinées and the streets are as gaily decorated as on public holidays. Such a children's day might bring in from £8000 to £10,000 in the whole country. One town—*Nagyvarad*—*has sent in* £200. The above sum, considering the fact that administrative work is done gratuitously, is a fair amount.

---

[1] This has already been published in pamphlet form by the Women's National Health Association of Ireland.

Reform of the Army Medical Corps.

A long-existing anomaly will be shortly abolished by the new organisation of the Army Medical Corps. The Government has been induced to take this step by the circumstance that for several years past there have been on an average only six applicants for ten vacancies. This was due to the low rate of pay and to the unsatisfactory position as regards relative rank of military surgeons in Austria-Hungary. The Minister of War now perceives that the dearth of military surgeons cannot be avoided without a substantial improvement in the rank and pay assigned to them. He has therefore lately decided that promotion shall be accelerated and that military surgeons shall have relative rank analogous to that of the combatant officers as is the case in the British Army Medical Service. Military surgeons will be accordingly designated surgeon-major, surgeon-colonel, and surgeon-general, in addition to which there will be several new titles created. A regular yearly allowance of £50 or £60 will also be given to medical students who undertake to enter the Army Medical Service after graduation.

April 16th.

Obituary.

MARY EDITH PECHEY-PHIPSON, M.D. BERNE, L.R.C.P. IREL.

THE death of Dr. Mary Edith Pechey-Phipson has removed from the ranks of medical women one who would have made her mark in any age and in any calling. It is now some 38 years since she went to Edinburgh to join Miss Jex-Blake in the struggle that was being made for the medical education of women. It is remarkable how great the courage and patience of that handful of women must have been, and "in those difficult and stormy days," writes Miss Margaret Todd, M.D., "Miss Pechey proved herself a loyal comrade and—what was wanted quite as much—an admirable student." It is not easy nowadays for a woman to surprise us greatly by the brilliancy of her record in the schools. 30 or 40 years ago the position was very different, for, handicapped by the shortcomings of their previous education, women found it no easy matter to shine in the examination room. But from the beginning of her career Edith Pechey raised a standard which has scarcely been overtopped. We again quote from Miss Margaret Todd's sympathetic letter to us:—"She brought to the study of medicine quickness of perception, neatness of hand, and a genuine love of science. Having passed a brilliant examination in arts, she proceeded to the classes of chemistry and physiology, and at the end of the session she stood first in chemistry among some 300 students, male and female, of her year. From that time on the curriculum of the women ran a somewhat chequered they had to build the walls of Jerusalem with the one hand and the trowel in the other; but in Pechey obtained her diploma from the Irish C Physicians and in the same year the degree of M.D. University of Berne. Immediately after graduation fortunate enough to obtain a post in Birmingham Lawson Tait, from whom she gained that experience minal surgery which was to stand her in such stead, and after practising for a short time in Leeds appointed to the control of the newly founded Kan pital in Bombay. The opportunity was a fine one was the very woman for the task. The whole sch providing medical aid for the women of India was its infancy and much of its subsequent success is du masterly fashion in which she planned out the work, acting in firm adherence to the best ethics of the pro A dispensary was speedily opened and by the end of a w patients were seen daily. The opening of the hospital fo with as little delay as might be, though the cosmo character of Bombay and the many races and castes had to be reckoned with made the task a very difficu Quickly establishing a creditable record in major she organised the work of the hospital and, in the te native prejudice, revolutionised the whole system of At the same time, her strong and picturesque pers gave her a position to which the women who followed steps owed much. She was appointed a member *Senate of Bombay University*, an honour which so fallen to the lot of no other woman. Some years befo she had married Mr. Herbert Phipson whose scientific proved a bond of common interest. Jointly they foun philanthropic sanatorium in the Deccan and purs study of many scientific and social questions."

From the first she had found the climate of Bomb trying, aggravated as were its effects by hard w heavy responsibility. After some 10 years of service she retired from her post with broken he on the outbreak of the plague in 1896 she was am first to organise and to take part in the house-to-hous tion. To the end of her life she retained her keenne intellect and her extraordinary grip of all que scientific and social—of the day. She was a loyal brilliant hostess, and a very kind woman. She died what unexpectedly from a chronic malady at Folke April 14th.

OSWALD AUCHINLECK BROWNE, M.D. CANT F.R.C.P. LOND.

To his many friends the news of the death of O Auchinleck Browne, which occurred on April 9th, have come as a sad surprise, for but little had heard of any illness. As a matter of fact, however, th stands thus. For some time past he had been subj attacks of acute abdominal pain and at last an op was considered necessary. This was performed succes when the trouble was found to be due to duoden among other causes. On the afternoon of April sudden attack of cardiac failure set in, from which he rallied. Dr. Browne was born in 1855 and wa cated at Harrow and at Trinity College, Cambridge, he received his medical training at St. Barthol Hospital, London. He qualified as M.R.C.S. En 1881 and from 1882 to 1883 held the post of physician to Dr. S. J. Gee. In 1884 he graduated Cantab., proceeding to the degree of M.D. in 1897. He b a Member of the Royal College of Physicians in 1886 Fellow in 1898. He was casualty physician at St tholomew's Hospital during the years 1886, 1887, and being also elected physician to the Royal Hospit Diseases of the Chest, City-road, in 1886. In 1890 h elected assistant physician to the *Metropolitan Hospit* in 1903 was appointed consulting physician, and same year he was appointed assistant registrar of the College of Physicians. Dr. Browne was a man of larly modest and retiring disposition and the many works which he did were known to very few others those who benefited thereby. He was an earnest Church and took a deep interest in the Universities Missio Central Africa, of the medical board of which he wa a long time a most valued member. Outside the more p medical aspects of his calling he was for many years o the churchwardens of the parish of St. Mary Magd Munster-square, where as chairman of the school mana son of Dr. J. B. Aickin of Belfast, studied at Queen's College, Belfast, and graduated M.D. of the old Queen's University in 1855 and in 1856 he became M.R.C.S. Eng. He practised in Belfast where he succeeded his father as surgeon to the Royal Irish Constabulary. He was also police surgeon and medical attendant to the members of the Fire Brigade. Dr. Aickin leaves a widow and family of three daughters and two sons.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Stomatitis due to Grey Oil.

AT a meeting of the Hospitals Medical Society held on March 20th M. Gaucher and M. Bory brought forward eight cases of mercurial stomatitis due to the use of grey oil. Of these eight cases six proved fatal. The stomatitis began just like an ordinary stomatitis but in all cases on the right side; it then rapidly became of a gangrenous nature and mercurial necrosis of the maxilla occurred, preceded by necrosis of the submaxillary tissues. The cause of death was either asphyxia, despite the performance of tracheotomy, or else a general septic infection. The doses given were, it is true, large, for they amounted to ten centigrammes, but even larger doses of mercury have been given without evil result. M. Queyrat pointed out that the quantity of grey oil injected was an important point and so also was the technique of the injection. The fact that nodules persisted after the injection ought to have given warning that further injections should not be made. The treatment which he considered most successful in such cases was a daily injection of 0·05 cubic centimetre of colloidal platinum as well as an injection of isotonic sea-water. Further, before commencing the treatment the state of the mouth and of the renal functions should be carefully investigated, and the flask containing the grey oil should be well shaken so that the mercury contained in it should be uniformly distributed.

The Academy of Medicine.

On April 7th the Academy of Medicine nominated M. Dastre, already a member of the Academy of Sciences, as member in the section of anatomy and physiology.

A Hospital Drama.

On April 13th Dr. Civel, physician to the Civil Hospital at Brest, was seeing his patients, when one of them, aged 63 years, suddenly drew a six-chambered revolver and fired at him. The bullet missed Dr. Civel but found its billet in the right elbow of an old man who was in the room. The man tried to fire again but Dr. Civel grappled with him and succeeded in disarming him; the excuse of the assailant was that Dr. Civel had failed to cure him.

Obituary.

The Paris Faculty of Medicine has recently suffered severe loss by the death of two of its most eminent members, Professor Terrier and Professor Cornil. Professor Terrier, who died on April 8th, aged 71 years, was elected an *agrégé* professor of surgery in 1872. Later as surgeon to the hospital he became well known to the younger generation of students by his completion of Jamin's classic Handbook of Minor Surgery. He became a member of the Academy of Medicine in 1890 and professor at the Faculty in 1893, while he made the Bichat Hospital, at which he worked, a school of surgery and a centre of teaching the influence of which was very great. As director of the *Review of Surgery* he published, either alone or in collaboration with his pupils, a large number of works dealing with almost every branch of that art, more especially dealing with the surgery of the intestine, the stomach, and the liver, for which he had a universal reputation. He was a man of the highest integrity and of marked uprightness of character, though perhaps a little unbending. Four days after the death of Professor Terrier Professor Cornil passed away. He died on the evening of April 12th at Mentone, where he had been staying for some weeks with a view to re-establish his health, and with his death there passed away one of the greatest masters of pathological anatomy and of microscopical science. He was born at Cussey, in the department of the Allier, in 1837, and became an *agrégé* of the Faculty of Paris in 1869. He was physician to the hospitals and a member of the Academy of Medicine and in 1882 he succeeded Charcot in the chair of pathological anatomy. He was closely connected with Gambetta and was at first Deputy and then for 18 years a Senator for his native department of the Allier. At the last senatorial elections he was not again nominated and last year he was put on the retired list which affected him profoundly. This event, which coincided with his non-election to the Institute, was the signal for the decline of his health. His published work was considerable. His manual of "Pathological Anatomy," published in collaboration with Professor Ranvier, is acknowledged as a universal authority. He also published a treatise on "Bacteria" in collaboration with Dr. Babès, a treatise on "Diseases of the Kidney" in collaboration with Dr. Brault, and a number of other works of which I may mention one in collaboration with Professor Chantemesse on "Pneumo-enteritis in the Pig" and others upon "Metritis" and upon "Syphilis." His later works, which deal with diseases of the bones and cartilages, were published in collaboration with his pupil, Dr. Coudray, and at the time of his death he was bringing out a work on "Mammary Tumours." He was President of the Anatomical Society and was the first President of the International Association of the Medical Press. In the Senate he introduced the Bill for the Protection of the Public Health. He was the type of the kindly *savant* and an untiring worker; not a day of his life went by of which he did not spend many hours in his laboratory at the École Pratique, where he gave advice to all who sought it with exquisite courtesy.

A Workman's Compensation Act.

During the week ending April 11th there was a meeting of a commission, originally appointed in 1905, composed of representatives of the medical profession, of pharmacists, of trade unions, of employers' associations, and of insurance societies. The meeting was held at the Ministry of Labour and the matter under consideration was the tariff of fees due to medical men and pharmacists in the case of accidents to workmen. After a lengthy discussion, and following on certain observations made by the representative of assurance and provident societies, the commission came to the conclusion that the most efficacious way of safeguarding the free choice of a medical attendant for the victims of industrial accidents and of avoiding the piling up of expenses which might be a heavy tax upon labour was the following. It was proposed to establish, after consultation between the medical profession and the insurance societies, a normal tariff for medical expenses drawn up according to the different categories of accident. In the case of exceptional accidents, however, this tariff should be capable of being modified in either direction, and the amount of increase or reduction should be appraised by an arbitration committee representing the various interests at stake. The commission unanimously agreed to the principle of this solution of the question at issue.

April 21st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Balneological Association.

THE meeting of the German Balneological Association was held this year at Breslau, Professor Brieger being in the chair. Professor Strümpell (Breslau) read a paper on the Treatment of Bronchial Diseases by Electric Light Baths. He said that he had obtained good results, especially in dry bronchitis and in asthma; in every case a careful examination of the heart should be made previously to the treatment, because certain cardiac diseases and also sclerosis of the aorta might present the appearance of chronic bronchitis. Typical fits of bronchial asthma and chronic dyspnœa caused by bronchiolitis were both of them favourably influenced by exposure to the electric light. The treatment must be commenced very cautiously, beginning with an irradiation whilst the patient is in bed; afterwards he might be put into the inclosed bath chamber and stay there in the presence of the medical attendant. Inveterate bronchitis has been recovered from after five or six applications of the electric light. In very severe cases the use of the electric light might be combined with medicines, such as iodide of potassium. Absolute rest was essential for the treatment and for this reason better results were obtained in hospitals and sanatoriums than when for the quieter patients. There are tennis and croquet grounds for the nursing staff whose indoor comforts have also been carefully studied. The general bathing of the patients is on the spray system which has been found more expeditious and economical of water than the more general open bath system. As regards the various installations required in an institution of this kind, such as fire-extinguishing apparatus, departmental telephone service, and electric tell-tale apparatus, the hospital is well equipped. The low-pressure hot-water system is employed for heating the rooms and corridors. A central power station generates current for all necessary purposes. The committee is to be congratulated on having provided a pathological laboratory and an operating room, both well equipped; also rooms and appliances for electro-therapeutics, and all clinical appliances likely to be of service. These facilities, combined with the advantage of proximity to the Cardiff Infirmary and the laboratory of pathology and bacteriology at the Cardiff University College, will doubtless be appreciated by the medical staff of the new mental hospital and will tend to promote scientific work in connexion with it.

THE Royal Dental Hospital, Leicester-square, has received a donation of 50 guineas from His Majesty the King.

THE CASE OF CROPPER *v.* STOKES.—At an extraordinary meeting of the Islington Medical Society held on *April 14th it was resolved*:—

> That the members of the Islington Medical Society, in special meeting assembled, express their sympathy with Dr. Henry Fraser Stokes in respect of the case of Cropper *v.* Stokes. They refer especially to the extraordinary remarks of Judge Edge on the evidence of the defendant, an old and well-known member of the society, and the refusal of his honour to allow any appeal or facilitate any rehearing of the case.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co. announce for publication to-day, Friday, April 24th, a volume upon "Electrical Treatment," by Dr. Wilfred Harris, and "Diseases of the Nervous System," by Dr. H. Campbell Thomson.—A new journal, entitled the *Zeitschrift für Laryngologie, Rhinologie, und ihre Grenzgebiete* (*Journal of Laryngology, Rhinology, and Allied Departments of Surgery*), will appear every two months, the annual subscription being 24 marks, to be paid to the publishers, Curt Kabitzsch (A. Stuber's Verlag), Würzburg. It will be edited by Dr. Felix Blumenfeld of Wiesbaden, with the coöperation of specialists.

THE MUNICIPAL EXHIBITION.—Having in view the great amount of interest which has been created in connexion with the use of x rays in hospitals, the management of the Municipal Exhibition, which will be opened at the Agricultural Hall on May 1st, has arranged with Mr. Alfred E. Dean to instal an x ray apparatus in a special building in the hall, and to give demonstrations illustrating its use, to be carried out at certain hours each day. The public are promised the opportunity of seeing the latest scientific developments in actual use. A new system of constructing fire-proof floors and partitions will also be on show, and will be of interest to the many medical men concerned in the conduct of institutions, such as hospitals, infirmaries, asylums, and retreats, where a rapid outbreak of fire would constitute a most appalling tragedy.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The spring meeting of the South-Eastern Division of this association will be held, by the courtesy of Dr. W. J. Seward, at the London County Asylum, Colney Hatch, on Tuesday morning next, April 28th. After inspection of the asylum and grounds, Dr. Seward will provide the members with luncheon (1.30 to 2.30 P.M.). Then follow a meeting of the divisional committee and at 2.45 P.M. the general meeting. After the transaction of formal business the following communications will be made:—Dr. Seward: "Notes on the History of Colney Hatch Asylum." Mr. W. C. Clifford Smith: "A Descriptive Account of the Buildings now in course of Erection at Colney Hatch Asylum." Dr. D. G. Thomson: "A few Remarks on the Teaching of Psychology." Dr. Harvey Baird: "Some Observations on Insanity in Jews." The members will dine together, after the meeting, at the Café Monico, Piccadilly Circus, London, W., at 7 P.M., provided that a sufficient number agree to dine. The price of the dinner is 5*s.*, exclusive of wine.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THE following answers to questions which were on t of Tuesday, April 14th, were circulated on the following

The Inspection of Imported Meat.

Mr. FIELD asked the President of the Local [illegible] whether he was aware that the Glasgow veterinary opinion that all meat imported from over seas ought to for examination in such form as would enable inspectors revise the previous work of inspection and thus form a the wholesomeness *for* human food, and that all boneless scrap should be entirely excluded; and whether the would consider the advisability of appointing and of inspectors.—Mr. BURNS wrote in reply: My attention called to this report. I propose that the regulations Health (Regulations as *to Food) Act which I have* in should deal with imported boneless scrap meat. Other relating to the wholesomeness of imported meat are attention, but I do not think that inspection of the kind the last part of the question would be practicable at the

The Post Office Medical Staff.

Mr. FIELD asked the Postmaster-General whether he would amount of sick leave and annual leave *respectively of each of* Office medical officers in London, male and female, during *last five years.—Mr. BUXTON replied: I annex a statement* sick leave of the Post Office headquarters medical staff during five years and the annual leave to which each medical officer is The third assistant medical officer and the resident medical been omitted, as they have not yet been employed for a full 1907 no sick absence was granted.

—	Sick absence.				Ann all

Mr. FIELD also asked the right honourable gentleman to st name, age, length of service, medical qualification, salary imperial funds, and emoluments from other sources of each Post Office medical officers in London, male and female.—Mr. answered: There are over 90 medical officers in the London district in addition to the headquarters staff. The preparation return asked for by the honourable Member would involve consi labour without, as it appears to me, leading to any very useful re

Appointments.

Successful applicants for Vacancies, Secretaries of Public Instit and others possessing information suitable for this column, invited to forward to THE LANCET *Office, directed to the Editor, not later than 9 o'clock on the Thursday morning of week, such information for gratuitous publication.*

APPLEYARD, WILLIAM, M.B., B.S. Lond., F.R.C.S. Eng., has appointed Senior House Surgeon at the Wolverhampton Staffordshire General Hospital.

ASKINS, J., M.B., B.Ch., B.A.O. Dub., has been appointed Medical spector of School Children by the Merthyr Tydvil (Glamorgan Education Committee.

BARRY, J. P., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appoi Certifying Surgeon under the Factory and Workshop Act for Inistioge District of the county of Kilkenny.

CASEY, CHARLES, L.R.C.S. Irel., L.A.H. Dub., has been appoin Medical Officer and Medical Officer of Health to No. 2 Distric the North Dublin Union.

CURTIS, C. F., L.M.S.S.A. Lond., has been appointed Assistant Ho Surgeon at the General Infirmary, Stafford.

DAVIES, IVOR J., M.B., B.S. Lond., has been appointed Senior Ho Physician at the Royal Free Hospital.

DUNN, ARTHUR GIBSON, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lon has been appointed Resident Medical Officer at the Newcastle-up Tyne Dispensary.

EDWARDS, H. J., M.D. Durh., D.P.H., has been appointed Certify Surgeon under the Factory and Workshop Act for the Lyn District of the county of Devon.

FOTHERGILL, W. E., M.D., C.M. Edin., has been appointed Honora Assistant Gynæcological Surgeon to the Manchester Roy Infirmary.

FERGUSON, J. M., L.R.C.P. & S. Edin., D.P.H., has been appointed Cer fying Surgeon under the Factory and Workshop Act for the Sou Burnley District of the county of Lancaster.

robable that suggestion played a prominent part in obtaining the good results. Professor Israel-Rosenthal agreed with Professor Gram. In one case which he had seen there was pronounced improvement after each bath, but the disease (chronic nephritis and myocarditis) nevertheless progressed with extraordinary rapidity. Professor Friedenreich pointed out that it was often very difficult to arrive at a prognosis in cases of angina pectoris and that the patients often rallied spontaneously in a most surprising way. One patient, whose condition he had regarded as hopeless, lived for 15 or 20 years afterwards. Professor Henriques discussed the theoretical foundation of the treatment. That it brought about hyperæmia of the skin could not be doubted. Dr. Hasselbalch had further found that the pressure in the brachial artery was lessened, but this did not show that the aortic pressure also decreased, so that the chief contention on which the treatment was based could not be considered proved. But even if the aortic pressure really became less the treatment might be dangerous in many cases; for instance, in hypertrophy of the heart in renal affections, for in these patients the high blood pressure is very important. Dr. Jacobæus agreed with Professor Henriques in what he had said about the aortic pressure. But it was undeniable that dilated hearts contracted under the light treatment, so that it was necessary to presume that the dilatation of the vessels of the skin brought about a decrease in the aortic pressure.

Recently a fresh discussion on the same subject took place on the occasion of a communication made by Dr. Bie and Dr. Bing to the Society for Physical Therapeutics and Dietetics. These investigators had tried to apply the treatment to heart diseases and other affections in the Kommune Hospital of Copenhagen. Instead of using a 150 ampères arc lamp, as Dr. Hasselbalch and Dr. Jacobæus had done, they had employed the far less costly "uviol lamp," a mercury incandescent lamp with "uviol" glass. The light of this lamp contains plenty of the effective ultra-violet rays but only few of the particularly heating rays, so that it is possible to place the lamp quite near to the skin. An illumination of the skin for a period varying from 15 to 30 minutes with the lamp at a distance of from 15 to 30 centimetres results in a very pronounced erythema of the same intensity and duration as that brought about by the arc lamp. The skin retains its scarlet colour for about one week, after which desquamation sets in and pigmentation takes place, so that after two weeks the skin becomes of a brownish tinge. But even several months after the light bath a slight remnant of dilatation of the vessels of the skin was discernible. Though it is scarcely to be expected that the dilatation takes place in more than a few tenths of a millimetre of the uppermost layers of the skin, it is not a small quantity of blood that the skin can absorb in this way. How this may influence the circulation can scarcely be estimated in the present state of physiological knowledge. The patients treated had chiefly suffered from neurasthenia or diseases of the circulatory system. The most pronounced improvement occurred in the neurasthenic cases. The patients suffering from heart disease were, as a rule, improved to a certain degree, in so far as they complained less of pain or insomnia. But trustworthy data for the estimation of the improvement were unfortunately not available. Further investigations were needed in order to make out the indications of the light bath treatment. Dr. Hasselbalch thought it important for the future of the new treatment if a cheaper and less intense source of light than that which is used in the Finsen Institute should prove useful. He said that his latest investigations had shown that the light treatment, amongst other effects, brought about (1) an increase of the total capacity of the lungs, due to augmentation of the inspiratory innervation; (2) a decrease in the respiratory frequency; and (3) an augmentation of the *so-called* pulse pressure. Dr. Jacobæus said that he regarded the light bath as a valuable help in various diseases, including cardiac affections, and that he had particularly noted its good effect on the painful attacks of angina pectoris. Dr. E. E. Faber said that in his opinion the alteration of the respiration and circulation brought about by the treatment was too small to explain the good results and that the treatment perhaps had more of psychical influence than was *commonly* supposed by its advocates. Professor Israel-Rosenthal said that he felt somewhat astonished at the roseate tints in which Dr. Jacobæus had depicted the results of the treatment. He had himself seen eight or nine of the patients treated at the Finsen Institute and of these not one had been conspicuously improved. Only one had improved considerably and this improvement had merely been transitory. In all the remaining patients the effect had been *nil* or very slight and transitory, probably due to suggestion. It was not to be forgotten that the whole apparatus and procedure of the light bath treatment were admirably fitted to act by the power of suggestion, and pain, even if due to organic lesions, might undergo temporary relief due to suggestion. He felt bound to mention that he had heard of two cases with good results, but even in these the improvement soon passed away. His experience was consequently the opposite of that of Dr. Jacobæus. Dr. Clod-Hansen reminded the meeting of the many wonderful cures of stenocardiac attacks effected by Pastor Kneipp in Germany only by pouring cold water on the feet and legs of the patients. In these diseases suggestion counted for much.

Postponement of a Medical Congress.

It is much to be regretted that the political tension existing between Sweden on the one side and Denmark and Norway on the other, ever since the declaration of independence on the part of Norway, threatens to prevent the Scandinavian medical men from meeting as usual at the Congress of Internal Medicine which was to be held in Bergen this summer. The Congress has been postponed, as the Swedish members of the committee have resigned. Representatives of the four nationalities concerned—namely, Denmark, Finland, Norway, and Sweden—will presumably meet in Copenhagen and consider the best means of restoring the good understanding which ought always to reign amongst members of our profession.

Death of Professor Lennander.

By the death of Professor Karl Gustav Lennander of Upsala Swedish surgery has lost one of its most eminent representatives. He was only 51 years old when he died, having for several years struggled with exceptional fortitude against chronic heart disease. Professor Lennander was particularly interested in abdominal surgery and was the author of a long series of important contributions to this branch of modern surgery. His investigations into the sensibility of the different organs, and particularly of the peritoneum, made his name very widely known. He suggested an original method of avoiding thrombosis of the veins of the lower extremities after abdominal operations, the chief point being the elevation of the foot of the bed. The deceased has bequeathed his considerable fortune and library to Swedish medical institutions.

April 20th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Urethroscopic Diagnosis of Gonorrhœa.

ONE of the most active of the Hungarian urologists, Dr. Joseph Sellei, has written a small work on the diagnosis of urinary diseases. He was induced to undertake this task, as he says in the preface, by having had under his observation a great number of cases of gonorrhœa which had persisted in spite of treatment. On inquiring into the reason of this he came to the conclusion that the want of success was due to improper therapeutic measures owing to incorrect diagnosis. Most patients stated that no urethroscope was used in their treatment. Dr. Sellei says that the use of the urethroscope is indispensable for arriving at a proper diagnosis and in his opinion a urethroscopic examination is not complete unless a magnifying glass is used. Methods of magnifying the visual field have been suggested by several experts but their instruments have not been favourably received by the specialists. Dr. Sellei has, however, succeeded in devising a urethroscope which answers all requirements. He adapts an auxiliary rail to the handle of the lamp-holder and on this there is mounted a magnifying glass which can be pushed to and fro and the centre of which coincides with the optical axis of the urethroscope. This glass can be turned into a variety of positions in order to allow the introduction of a small tampon into the tube. With this modification the dispersion of light is avoided so that the image becomes clearer and the visual field is also considerably enlarged.

The Protection of Children.

A couple of years ago a movement was started in Hungary

Notes, Short Comments, and Answers to Correspondents.

POISONING BY TRIONAL.

THE following brief note of an interesting case of poisoning by trional has been sent us by a well-known medical man who regrets that his name must not appear in connexion with it. The patient is to be congratulated upon the prompt and skilful treatment which he received:—

> After taking, on his own initiative and without medical advice, 15 grains of trional for 32 nights a man suddenly became comatose. Found at 7 A.M. in his bedroom in this state; the writer saw him at 7.50 A.M. He was absolutely stupefied, could in no way be roused, all reflexes absent, respirations eight per minute, temperature (rectal) 97·2°; no water in bladder. The writer tied a catheter in the bladder and relied on saline injections, subcutaneous and rectal. Urine began to dribble from the bladder in an hour (exactly) and by pushing the salines a steady flow of urine was established. As soon as the kidneys were deemed to be doing good work food was given per rectum at regular intervals. From 7 A.M. till 2 A.M. of the next morning the coma did not lift. After 19 hours (but probably much longer as we had no data as to the time of its incidence) the coma began to have intervals, querulous and questioning, with long lapses of minor coma and finally long sleeps. From the time he was found till the time he recognised the writer (whom he knows well) was 72 hours. His proper adjustment of vision did not ensue for five days and the power over his bladder did not completely return for six days. The writer has never before seen toxæmia from this drug and probably the bare facts may be of interest to your readers.

MEDICAL FEES UNDER THE MIDWIVES ACT.

To the Editor of THE LANCET.

SIR,—In October last the guardians of Nottingham issued circulars to the medical practitioners of the district informing them that they had adopted the recommendation of the Local Government Board and that "if the guardians are satisfied that the husband or natural guardian of the patient is too poor to pay for her necessities they will exercise the powers given them and pay a fee of 21*s.* in each case (and a higher fee where exceptional circumstances warrant it) in which medical assistance has been rendered on the application of a midwife."

About two months ago I was sent for by a midwife who had difficulty in delivering the after-coming head. I sent in an account for 21*s.* to the guardians and the enclosed is a copy of the clerk's reply. I hold that this was a case that should be paid. The man had to make an allowance to his wife's parents for board for two people.

No county court judge would make an order against a man earning only 20*s.* a week and yet the guardians think he is quite able to pay. Any case poorer than this one would expect to be attended by the parish doctor. I would be glad to have your opinion and that of your readers on the subject.

I am, Sir, yours faithfully

Nottingham, April 18th, 1908. WILFRID J. H. HEPWORTH.

[INCLOSURE.]

Poor Law Offices, Nottingham,
Feb. 18th, 1908.

Midwives Act, 1902.

DEAR SIR,—With reference to the case of *Mrs. S—— of ——street* and your claim upon the guardians for payment of a fee of 21*s.*, I am instructed to refer you to the woman's *husband for payment* of the fee. The man earns 20*s.* a week, has no children, and lives with his *wife's parents, consequently* the guardians consider he should be responsible for it.

Yours truly,
G. M. HOWARD,
W. H. Hepworth, Surgeon. Clerk to the Guardians.

⁂ We should certainly have thought that the fee, though the lowest fee possible in the circumstances, was out of the range of the patient's husband.—ED. L.

HEALTH REFORM IN GLASGOW.

DR. A. K. Chalmers, medical officer of health of Glasgow, recently delivered an interesting lecture on the subject of Practical Health Reforms under the auspices of the Glasgow Health Culture Society. In dealing with the subject he referred more especially to the problem *of town* population, which was increasing to such an extent that now almost 75 per cent. of the population lived in towns. It was being earnestly asked what was the effect of town life on individual resistance to disease. It was not wholly a question of fatal disease, but of the vigour of the survivors. He believed that the two were *correlated, although* the *reports* of some friendly societies appeared to indicate that both the sickness-rate at given age periods was *now greater* than *formerly,* and that the sums paid annually in sick relief exceeded the annual contributions and could only be met *from* the proceeds of invested capital. These were serious suggestions if they righ the facts. The facts, however, were not wholly tions of town life. The average boy in secondary was physically fitter than the average boy of rural was wanted was not a record of mortality but of vit to be accomplished by a national stocktaking of and fitness, medical inspection of school children, an of hygiene. There would be fewer dirty and unventila a much better selection of the foodstuffs for househol the teaching of hygiene to children undertaken in th the recent circular of the Education Department ducing. The modern city was ill-adapted to the need There was need for a playground for each tenement, atmosphere, and a pure milk-supply.

IMPROPER ADVERTISEMENTS.

A MEDICAL man has sent us the red cover of a p magazine, dated April 23rd, on the inner page of wh what astonishing array of advertisements. Ther advertisements of so-called "Ladies' Remedies," and the advertisement is worded so that it may make th that she is purchasing something that will bring on period. They are said to contain pennyroyal or apiol *fail to give relief,* although they do not contain penny is not one of them that cannot be detected at once advertisement, in *view of the fact that during the* period suppression of menstruation is generally due There are four *invitations to* "weak" men or "nervou pamphlets which will teach them how to re-create the there are ordinary advertisements of quacks. We fear anything in the matter, though we are obliged to our for inviting our attention to it. We could pillory the pr paper in question, but he must know the way in whi is being made, so that there is no reason to suppose he his tactics. Nothing that we said about the morals of people who prey upon the sexual weaknesses of the cause them to suppress their advertisements. As lo obtain a place for their advertisements in newspaper they advertise. Our opinion of their character is, of consequence to them. The public has the remedy in If a large section of the public were to write to the pro paper in question and say that they declined to enter hi competitions until he had purged his advertise from filth, every one of these advertisements would next day. They are inserted *because there is money* they would be suppressed the moment money began them.

RETURN TO LIFE.

A SENSATIONAL story *has been going around conc* return to life of a dead patient. Medical men bored lately by sensational and unwarranted stat the frequency with which burial alive takes p *suggestion being frequently* added that these hor medical carelessness. We have no doubt whateve *case is filed for future reference* as one of suspend where the medical man was deceived into believing th was dead, and it may be so used for platform purposes turned out that the medical man had never believed be dead, but that the patient's friends had misunder said and had already taken steps to draw the insurance patient and his family came of a thrifty race.

his medical knowledge found much scope for good Like his namesake Sir Thomas Browne, he was the the cultured and learned physician, one who ever him the motto of Manchester al Mondo—

that would end his dayes well must spend them well."

RY COLLIER LECKY, M.A., B.M., B.CH. OXON., D.P.H. OXON.

announced a fortnight ago, Dr. H. O. Lecky died ex County Hospital, Brighton, on March 31st. commenced with dramatic suddenness, as he a shop at Brighton, was taken to his rooms, found to be suffering from a right-sided pleurisy. later pneumonia developed; subsequently the g became involved and death occurred at about the third week. Up to the time of his illness for Dr. Lecky had been acting as medical officer of Brighton; previously to this he had for two years acted as resident medical officer of h sanatorium and deputy medical officer of Brighton; he had also held important resident at St. Thomas's Hospital, London, and the Infirmary, Oxford. Death has thus cut short at what promised to be a more than usually useful career, for Dr. Lecky was but 29 years Highly trained, devoted to his scientific studies, a l and exact investigator, and one who never t and laborious work, it seemed to his numerous friends that he had a splendid future before him. had much to do with students writes: "A loss knew him personally, he is no less a loss to the profession. He will pass in my memory to a very of young men of the highest promise, eight or . Throughout life he possessed to a remarkable power of making friends and no one was ever the friendship."

Brighton a similar testimony to Dr. Lecky's winning , for a medical friend writes from there: "In we had known him at Brighton we had come him. His brightness, unselfishness, and unfailing kindness to all compelled affection. I never a word I would have wished unsaid and never do a thing I would have wished undone. His was almost a source of weakness, so over anxious always not to hurt another's feelings. I cannot er character quite like his."

that these brief lines in memory of Dr. Lecky's personality and of the high standard of life which himself will be a source of gratification to the who are now regretting his untimely death.

Medical News.

Before going to Bonn in 1900 he was Assistant in the Medical Policlinic in Berlin for 16 years.—*Erlangen:* The Bavarian Academy of Sciences has granted Dr. Richard Fuchs, *privat-docent* of Physiology, 1500 marks (£75) for the purpose of his researches on the effects of the air at high altitudes on the human body.—*Florence:* Dr. Antonio Mori has been recognised as *privat-docent* of Operative Medicine.—*Königsberg:* Dr. Siegfried Hammerschlag, *Oberarzt* of the Gynæcological Clinic, has been appointed Professor of Gynæcology.—*Paris:* Dr. Gley, whose researches on the physiology of the thyroid gland are well known, has been appointed to the Chair of General Biology in the Collège de France.—*Padua:* Dr. Luigi Peserico has been recognised as *privat-docent* of Medicine.—*Palermo:* Dr. Santi Pusateri has been recognised as *privat-docent* of Otology and Laryngology.—*Pavia:* Dr. Gaetano Ronzoni has been recognised as *privat-docent* of Internal Pathology, and Dr. Domenico Pane as *privat docent* of Bacteriology.—*Philadelphia* (*Jefferson Medical College*): Dr. Hiram L. Roux has been appointed Assistant Professor of Diseases of the Genito-Urinary Organs.—*Prague* (*German University*): Dr. Konrad Helly has been recognised as *privat-docent* of Pathological Anatomy.—*Strasburg:* Dr. Heinrich Kraft, *privat-docent* of Hydrotherapeutics, has been granted the title of Professor.—*Tomsk:* Dr. A. Lindström of Kieff has been appointed Extraordinary Professor of Dermatology.—*Vienna:* Dr. Hans Eppinger of Gratz has been recognised as *privat-docent* of Medicine.—*Zürich:* Dr. M. Rodari has been recognised as *privat-docent* of Gastro-Intestinal Diseases.

CARDIFF CITY HOSPITAL FOR MENTAL DISEASES.—This institution was formally opened by the chairman of the visiting committee, Councillor Morgan Thomas, on April 15th, in the presence of the Lord Mayor of Cardiff, the corporation, and a large number of guests. After a tour of inspection, during which great satisfaction was expressed with the arrangements for the patients' comfort, visitors were entertained to tea in the recreation hall by the chairman and members of the visiting committee. The buildings are grouped about a main corridor of horse-shoe shape, the wards being arranged in intercommunicating blocks which radiate from the convex aspect and face south, whilst the administrative offices, power-station, shops, &c., are on the inner aspect. The building has only two floors which will be found a great convenience in practice. The architects are Messrs. Oatley and Skinner of Bristol. There is no separate accommodation for private patients. In view of the undoubted need for suitable accommodation for mentally afflicted persons of the middle-class in South Wales, it is to be hoped that the committee may ere long see its way to erect two separate houses, for the two sexes, on the estate which covers 120 acres. The cost of the site was very considerable, the land being "accommodation" land, well suited for the purpose in view, with a gravelly soil, and only 15 minutes from Cardiff by rail. On the other hand, since building operations were commenced a suburb has sprung up round about the hospital, causing it to be somewhat overlooked and increasing the anxieties with regard to the supervision of patients. The total cost of the land and the buildings is approximately £350 000. The cost of furnishing and equipment, including all fixtures and also the church and recreation hall and farm equipment, amounts to £24,000. The wards accommodate 750 patients but administrative accommodation for 1250 exists, so that future extension of wards is provided for. The medical superintendent's residence is situated some 250 yards from the building and the three assistant medical officers provided for are housed in a block communicating with the corridor of administration. Gardens for exercising the patients are laid out on the southern aspect of the building and include tennis courts

P.M. and 9.30 A.M.), West London (2.30 P.M.). Hospital (2 P.M.), the Royal London Ophthalmic Westminster Ophthalmic (1.30 P.M.), and the mic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 15 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and *Post Office Orders (crossed* "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.
